Without placing entire faith in Manship's conclusions, however, there is sufficient evidence of the antiquity of the Yarmouth herring fishery; and as it keeps up its repute at the present day, and has indeed considerably increased in recent years, some details of its working may be acceptable. The nets used in the drift-fishing were formerly all made of hemp or flax, but for some years past cotton has almost entirely superseded these materials. Cotton nets are manufactured at Bridport, Manchester, Musselburgh, and other places, and are about 30 yards long and 9 or 10 yards deep. One of the long edges of the net, called the "back," is fastened to a rope corked at regular intervals, whose purpose is to keep that part of the net uppermost. The number of such nets used by each vessel depends chiefly on her size, and ranges from 80 to 130, or even more. They are fastened together end to end, and thus united form what is called a "train, fleet, or drift of nets," often extending to a length of more than a mile and a quarter. The size of the mesh was at one time regulated by law, and the smallest dimensions allowed in herring nets were one inch "from knot to knot along the line," or, to speak more concisely, one inch square. Under the present fishery regulations, however, it is wisely left to the fishermen to choose a mesh of such a size as will be most effective in catching the fish, and their practical good sense does not often lead them astray in this matter. With herrings of average size the inch mesh is found to do the most profitable work. An exception to this freedom from restriction to any particular sized mesh exists, however, on one part of the west coast of Scotland, and to that we shall direct attention when we speak of the Scotch fisheries. Twine nets are coarser than those made of cotton, and the material not being so flexible, machinery cannot be satisfactorily used in their manufacture; they are therefore netted by hand, and are made in narrower pieces called "deepings," which are laced together one below the other to make up the required depth. The labor of hauling in these nets is of course more severe than with cotton, on account of their greater weight and faculty of absorbing the water; and the comparative stiffness of the mesh is not so favorable to the capture of the fish when they strike the net. On the other hand, it was objected to the cotton nets that the thread was so fine as to cut into the fish which were meshed, and to tear off their heads as the nets were hauled in. Whatever force there may be in this objection, the advantages in time and labor saved both in making and working cotton nets have practically decided in their favor, and cotton is now almost universally employed in all our drift-fisheries. The object of the cork-rope is, as we have said, to keep that edge of the net uppermost, but in the ordinary net the corks are only sufficient for that purpose, and will not prevent its sinking. This is provided against by the use of buoys, or "bowls," as they are called, one being attached by a rope to each net, and by lengthening or shortening this rope the net can be kept at any distance below the surface that may be considered best for catching the fish. It is always a matter of uncertainty at what depth the fish may be found, and a good deal of judgment is needed in sinking the nets, if there are no signs of the fish being near the surface. It is found convenient to color these bowls so as to mark the divisions of the fleet of nets. The first net, or the one nearest the fishing boat, is marked by a small white bowl, called the "puppy," and at the end of the next four nets is a "dan," or buoy with a pole carrying a small flag. The rest of the nets are marked in four divisions; at the first quarter from the pole is a bowl painted one quarter red and three quarters white; the next is half red and half white; and at the beginning of the last division the bowl is three quarters red and one quarter white. All the rest of the bowls from the beginning to the end of the train of nets are entirely black. The only part of the gear in connection with the long string of nets is the warp, a stout rope to which each net is fastened by two smaller ropes called "seizings," and long enough to allow the warp to hang down near the foot of the nets. This warp has a two-fold purpose: it prevents the loss of the nets if by any chance a vessel should pass through and cut them when near the surface, an accident not unlikely to happen, as the nets are only used at night and extend a considerable distance, often in the course of trading vessels going up and down the coast; and it is by means of the warp the nets are hauled in, the strain being thus brought evenly, by means of the seizings, on each separate net. The Yarmouth drift boats are the largest used for this kind of fishing on any part of our coasts. They are fine decked vessels of about 36 tons, the largest being upwards of 52 feet on the keel, with about 17 feet beam and 7 feet depth of hold. The universal rig has long been that of a lugger, with two masts only, and they carry a jib, a large dipping fore-lug, and a mizen with a topsail. The mizen-mast is always kept standing, but the fore-mast is made to lower backwards when fishing is going on, so as to enable the vessel to ride easier, as at that time she is head to wind and without any sail that can steady her. The mast is not lowered on to the deck, however, but, as is the practice with all large drift-boats, the head is supported on a wooden crutch 10 or 12 feet high, in the Yarmouth vessels called a "mitch-board." In this manner the mast lies very snug, and does not interfere with the room on deck. The interior of the vessel is fitted up with separate spaces for the nets, warp, fish, and salt, of which last a quantity is always taken to sprinkle the fish with before they are stowed away. These boats carry as many as ten or twelve men, as the labor of hauling in the nets is considerable; but more than half the crew are landsmen who are mainly employed at the capstan by which the warp and nets are got in. Strength, and not nautical knowledge, is required for this work; and all the important part of the fishing—the deciding where to work and at what depth to place the nets—is the business of the experienced fishermen.

Drift-net fishing is with rare exceptions only carried on at night. The time for commencing is just before sunset, and the nets are then got into the water by the time it is dark. When the vessel has arrived at what—from certain indications, such as numerous seabirds or possibly fish playing at the surface, or even without any special signs to guide the fishermen—may be thought a likely place for fish, for there is a great deal of speculation in the matter, the vessel is sailed slowly before the wind, and if possible across the tide; then the net is shot or thrown out over the vessel's quarter, the men being distributed at regular stations, some hauling up the net from below, others throwing it over and taking care that it falls so that the foot is clear of the corked back; others, again, looking after the warp which has to be paid out at the same time, and seeing that the seizings are made fast to it in their proper places. When it is all overboard, and about 15 or 20 fathoms of extra warp, called the "swing-rope," given out, the vessel is brought round head to wind by the warp being carried to the bow; the sails are then taken in, the masts lowered, a small mizen set to keep the vessel with her head to the wind, and the regulation lights are hoisted to show that she is fishing. A few of the hands remain on deck to keep a look out, and the vessel and nets are left to drift wherever the wind and tide may take them. It is very rarely that there is an absolute calm at sea; and if there is the faintest breath of air stirring, the fishing boat will of course feel it more than the buoys supporting the nets; she will consequently drift faster, and being at the lee end of the train, will have a constant pull upon them, and so keep them extended almost in a straight line, so that every portion of the nets hangs clear and free from folds. If there is a great deal of wind more swing-rope is allowed, so that the nets may not be dragged through the water or any undue strain be thrown on the warp, as the more warp there is out the greater spring there is in it, and the less danger of its breaking. The first net in the train is called the "look-on" net, and frequently after an hour or so, that one is hauled in to see if any fish have been taken, and if so, in what part of the net. If it has been allowed to sink too low, that will be shown by the fish being only in the upper part of the net, or *vice versâ*. Such an examination of one of the nets (called in Scotland by the name of "preeing") also sometimes discloses the fact that dog-fish are unpleasantly abundant, and this makes it desirable to haul in the nets very soon, as these pests of the fishermen do a great deal of mischief to both the fish and the nets if they are allowed to remain long in the water. The operation of hauling in the nets is carried on in the same systematic manner as in the case of shooting them. The laborious part of the work is now performed by the "capstan-men," whose duty it is to heave in the warp, the regular fishermen looking after the net as it comes on board, and shaking out the fish, which is at once sprinkled with salt and stowed away in the fish room.

[1] *The Herring; its Natural History and National Importance* (1864).

[2] *History and Antiquities of Great Yarmouth*, p. 5 (1772).

After a day or two, depending on the success or failure of the fishing, the vessel returns to port; and the general practice since the opening of the extensive covered fish market by the side of the Yarmouth haven is for the luggers to go into the river and deliver their cargoes direct into the market. It is at times, however, a difficult matter to enter the haven, and then the old practice of landing the fish on the beach in front of the town is resorted to. The landing is effected by means of large "ferry-boats," which go off loaded with baskets of a peculiar shape, called "swills," each one capable of holding 500 herrings, and put them on board the lugger which is anchored at a short distance from the shore. The fish are then counted rapidly into the baskets, which are placed, when full, in the ferry-boat, and as soon as she is loaded she returns and is laid broadside on to the beach. A set of strong, active fellows, known as "beachmen," at once go to work, and two men taking each basket between them in their arms, soon carry up the fish to the carts waiting to take them either to the market or direct to the curing houses. The situation of the market by the side of the haven is very convenient; and, if required, more room can be easily provided by adding some of the vacant land immediately adjoining it, and with the same river frontage. The market was completed only in 1867, and although the Yarmouth fishery has been carried on continuously for many centuries, it is only since the opening of the new market that an accurate account has been kept of the quantity of herrings landed there.

The following statement shows the number of lasts of fish received at the market during each of the ten years 1868–77, and as a "last" of herrings contains 13,200 fish, some idea will be gained of the produce of the Yarmouth fishery, without taking into consideration what is landed elsewhere by Yarmouth boats:

Years.	Lasts.	Years.	Lasts.
1868	15,098	1873	18,796
1869	13,608	1874	17,724
1870	19,420	1875	11,820
1871	19,008	1876	12,824
1872	14,450	1877	18,900

The following is the mode of counting herrings on almost all parts of the east coast of England:

4 herrings = 1 warp.
33 warps = 1 hundred = 132 fish.
10 hundreds = 1 thousand = 1,320 "
10 thousands = 1 last = 13,200 "

Only 30 warps or 120 fish, however, go to a "hundred" of mackerel.

It will be observed that considerable fluctuations have taken place in the produce of the Yarmouth fishery during the last ten years; and there is no doubt that they have been almost entirely caused by variations of weather during the herring season.

Bloaters and red herrings.

A few words must be said here about the manufacture of bloaters and red herrings, which has made Yarmouth famous all over the world. The same mode of curing herrings is now adopted in many other parts of England and in Scotland, but the time spent on the operation is not in all cases the same.

As soon as the herrings are brought to the curing houses at Yarmouth, the fish are all washed to get rid of the salt they were sprinkled with on board the fishing boats, and then, without being gutted, or any other preparation, they are again put into salt, which is generally brought from Liverpool. Their subsequent treatment depends on whether they are to be made into red herrings or bloaters. The latter—Yarmouth bloaters, *par excellence*—are generally selected fish, full-roed and of the best quality. The finest are made in October and part of November, when the home fishery is going on, and they should be cured as soon as possible after they are taken out of the water. Strictly speaking, a bloater is nothing more than a herring that has been only slightly cured; it is kept in salt from twelve to eighteen hours, and then smoked for about twenty-four hours. But as any herring can be made into what may be called a bloater, and there being always a demand for them, their manufacture is carried on throughout the season with the best fish that can be obtained; and we need hardly say that bloaters are to be had all over the country, and cured in various places, which come far short in excellence of the selected Yarmouth fish. A properly cured bloater is ready for the market at once, and the sooner it appears on the breakfast table the better it is likely to taste. In the last few years some bloaters have been prepared at Yarmouth with even less curing than that we have spoken of, but they will not bear keeping very long. It is the practice at Yarmouth to keep the fish in salt for fourteen days if they are to be made into "red, well-cured, or high-dried herrings;" they are then washed and hung in wood-smoke for another fortnight. The curing is mainly done by women, and after the fish have been taken out of the salt and washed, they are "rived" or strung in "spits," or thin sticks, about 4½ feet long, which are thrust under one gill-cover and out at the mouth. Twenty-five fish are put on each stick. The spits are then taken to the smoke-room,—a lofty chamber, perhaps about 16 feet square, having a series of wooden frames reaching from floor to roof, with small transverse beams, called "loves," beginning at a distance of six or seven feet from the ground, and running, one above the other, from one side of the room to the other. The frames are four feet apart, and the spits are placed in rows between them, the ends of the spits resting on opposite loves. The roof is made of tiles, uncemented, so as to allow a good draught through the room, which when filled contains three lasts of fish. About sixteen fires are made on the stone floor of this room, the fuel generally being oak billets, which give a high color to the fish. Ash timber, producing a different color, is used in some cases, to suit the fancies of particular foreign markets. When the room has been thus filled with spits of fish, the fires are lighted and kept burning for two days; they are then let out, and the fish allowed to drip for a day; the fires are again kept alight for two days, and the process of alternately drying and dripping is continued for a fortnight, when the herrings are considered thoroughly cured, or high-dried, and are fit for packing. For the export trade they are packed in barrels, each of which should hold 650 good-sized fish, or a larger number of smaller ones. The manufacturer's name and the number of fish are marked on each barrel. The export trade is to Italy, the Greek islands, and the Levant. The time employed in curing these herrings is longer than is given in Scotland, but in some cases only half the usual time is allowed, and such fish are sent by steamer to the Mediterranean, where they are soon disposed of; but it is not considered safe generally to consign any but "well-cured" herrings to the foreign markets, especially in warm climates. For the home market both bloaters and "reds" are packed as a rule in flat boxes.

The drift fishery for herrings is carried on more or less along the whole east coast of England, throughout the English Channel, and to a small extent on the Welsh and western side of England. The seasons for this fishery differ, however, on different parts of the coast. It commences on the Northumberland coast in the latter part of July, becoming later as we go southward; at Yarmouth and Lowestoft the home fishery is in October and November; but a spring fishing has been made for some years past at Lowestoft, beginning at some distance from the land, and gradually coming nearer as the season advances. It is a fishery that has given rise to much complaint on account of the generally small size of the fish then caught. In the Channel herring-fishing goes on during November and December, and at the extreme west in the early part of the year. It is not a very important fishery there, however, and the attention of the fishermen is soon entirely given to the more lucrative fishing for mackerel, which may be said to have its headquarters at the mouth of the Channel, although the fish gradually advance eastward as the summer goes on.

Mackerel drift fishery.

The mackerel drift fishery is worked practically in the same manner as that for herrings, but a larger mesh is of course required, and about an inch and a half square has been found most suitable. That, however, is not the only difference between mackerel and herring nets. It is the special habit of mackerel to keep near the top of the water, and the nets are consequently so well corked as to float at the surface. It is also unnecessary to have the same depth of netting as when herring fishing, and what is saved in this direction is added to the length. A full train of mackerel nets as used by the large Yarmouth drift-boats is as much as 2½ miles long, or double that of a herring fleet. Twine was long used in their manufacture, but cotton has taken its place generally whenever new nets were required. Mackerel first appear in deep water south and south-west of the British Islands, and are sometimes caught as early as January many miles west of Scilly, but the general Cornish fishery does not usually begin till towards the end of February, and it extends into June. May, June, and July are the months in which the mackerel drift fishery is carried on farther up the Channel, and at the later part of that season in the southern portion of the North Sea. The important fishery for mackerel is, however, on the Cornish coast, and thither resort fishing-boats from Yarmouth, Lowestoft, and the various Channel ports, and, in company with the famous Mounts Bay luggers, devote themselves to the ingathering of this great harvest of the sea. Many thousands of tons of mackerel are landed at the western ports during the season, particularly at Plymouth and Penzance, and are sent away by rail to the London and other markets.

Pilchard drift fishery.

The pilchard drift fishery is worked in the same manner as that for herrings, but rather a smaller mesh is used, and herring nets which have shrunk too much for their original purpose are often usefully employed for the capture of pilchards. This fishery begins in July and continues till September. It is mostly worked on the coast of Cornwall, but during the last few years a great many of these fish have been taken along almost every part of the south coast of Devon. Pilchards may be regarded in England as essentially Cornish fish; there is very little sale for them out of their proper county, but there they are looked upon almost as one of the necessaries of life, and every household likes to have a store of salted pilchards for winter use. These are all the produce of the drift nets, the fish taken by the seans being cured for export to the Mediterranean. A new industry in connnection with the pilchard fishery has been recently established at Newlyn in Mounts Bay, and at Mevagissey, further to the eastward. This is the manufacture of "sardines," in precisely the same manner as has long been carried out on the French coast. The so-called "sardines," caught so largely in the Bay of Biscay, being nothing but young pilchards, there seemed no reason why the Cornish fish, if treated in the same way as the French, should not turn out as good. Curing-establishments were therefore set up at the two places named, and measures having been taken to insure a thorough knowledge of the French mode of curing, "Cornish sardines," or "pilchards in oil," were prepared, and with so much success that orders for them are now received for more than the present limited means of manufacture can supply.

Sardines.

Sean Fisheries.

Sean Fisheries.—Sean or seine nets are used on the English coasts chiefly for the capture of mackerel and pilchards, but sprats and various other fish are occasionally taken by them. The particular fishery with which this net is most commonly associated is that for pilchards at St. Ives, on the north coast of Cornwall, where seans are kept in readiness for working on a very large scale. For a long course of years St. Ives Bay has been more or less visited by shoals of pilchards, generally during the months of October and November. These fish are found in abundance off the south-west of Ireland rather earlier in the year, and it appears as if the shoals were returning towards the Bay of Biscay, when they arrive on the north coast of Cornwall in October. In their course southwards some of them enter St. Ives Bay and sweep around it, and if, in doing so, they come within a certain range of part of the shore, the seans are brought into play, and large captures of fish may be made. The seaning ground is on the western side of the bay, and extends southwards for nearly three miles from the bar. It is divided into six stations or "stems," by marks or boundaries on the land, in positions fixed by a local Act.[1] These stems have each a name, and no fishing boats besides those employed in the sean fishery are allowed to fish or anchor within a certain distance of the stems between an hour before sunrise and the same period after sunset from the 25th of July to the 25th of December; and any passing boats must keep near the shore. Under favorable circumstances the fishery is likely to be so valuable and of such general advantage to the town that the Act of Parliament regulating the proceedings is strictly carried out with the approval of all concerned. For this reason also no seans below a certain size are allowed to be used, so that the danger of disturbing a large body of fish, and perhaps frightening them into deep water without having secured a good haul, may be as much as possible avoided. The smallest sean of legal size at St. Ives is 160 fathoms along the cork-rope, with a depth of 8 fathoms at the middle or bunt and 6 fathoms at the ends or wings. Some of the seans are as much as 200 fathoms long, and the mesh in all is three-quarters of an inch square throughout the net. The object is not to mesh the fish as in a drift-net, but to inclose them. What we have described is the sean proper, but there is another of smaller size and different proportions which also takes part in the fishery. This is called a tuck-sean, and is only 70 to 80 fathoms long, but it is 8 fathoms at the wings and 10 fathoms in the middle or bunt. Besides these there are other nets called stop-nets, which are practically only additions which can be made to the principal sean, and which are so used when the sean is being worked. As there are about 250 seans at St. Ives, and only six stations in which they can be used, some arrangement is necessary to prevent confusion and interference, and this and other details are the subject of special regulations. The seans are all registered, and many of them belong to companies. Several boats are employed when a sean is to be shot. The largest, called the sean-boat, is about 32 feet on keel, with plenty of room for carrying the net; she has six men for rowing and two for shooting the sean. Two tow-boats about 24 feet long, and each carrying a stop-net, with a crew of six men, make up the working party; but besides these there is a small boat called the "volyer" or "lurker," from which the master seaner directs all the proceedings. The position of the shoals of fish is pointed out by men called "huers," who are selected from the sharpest and cleverest of the fishermen. There are generally two of them on the hill above each station, and when they see the shoals of fish, looking like the shadow of a cloud on the water, they signal with a large white canvas ball to the boats waiting below in the stations. These men remain on duty for three hours at a time, and receive £3 a month, and one hogshead out of every hundred hogsheads of fish landed. When the shoal has come within a convenient distance of one of the stations, the boats containing the sean and stop-sean, which have been previously joined together, commence shooting the nets at the same time, the larger net being thrown out in a direction parallel with the shore, while the stop-sean is shot in front of the shoal as the boat is rowed towards the land. The two boats ultimately turn towards each other, and gradually bring the ends of the nets together, thus cutting off and surrounding as many fish as they can. The second stop-net is joined to the first if there is a probability of its being wanted. The nets are then fastened together at the point of meeting, and the circle gradually contracted until all the fish are inclosed by the single large sean. The ends being securely joined and the stop-nets taken away, the circle of netting with the inclosed pilchards is slowly hauled towards the shore, into some quiet place as much as possible out of the run of the tide, till the weighted foot of the net touches the bottom, and there it is safely moored. The fish cannot now escape, and if the haul be a large one several days may elapse before they are all taken out. "Tucking" the fish is the next operation, and this is performed with the tuck-sean, which we described as being

St. Ives pilchard fishery.

---

[1] 4 and 5 Vict. c. 57.

very deep in the middle. It is shot in the ordinary way with one boat, but inside the other sean, and as it is hauled in, the foot of the bunt is raised so as to bring the fish to the surface, whence they are dipped out in large baskets and put into attendant boats to be carried on shore. This is of course the exciting moment of the day, and all the town is astir, and taking part in the general rejoicing. Landing and carrying the fish to the curing houses is done by men termed "blowsers," who are paid in proportion to the catch of fish. The seanmen receive certain wages in money and a share of the fish, and every household does a little curing on its own account. The great bulk of the fish, however, goes into the houses of the large curers, who are generally the proprietors of the seans.

Export of Pilchards to Italian Ports from 1815 to 1877.

Pilchard curing.

Women are employed in the curing, which consists in packing the pilchards in alternate layers of coarse salt and fish on the stone floor of the curing house," until the "bulk," as it is called, has reached a height of five or six feet. The fish remain here a month, and the oil and brine draining from the mass are carried off by gutters in the floor to a cistern. When the fish have been sufficiently salted they are washed and packed with the heads outwards in hogsheads, and a "rose" of fish in the middle to keep the level. Gradual pressure is now applied on top of the fish, until the contents of the cask have been reduced one-third in bulk, and a large quantity of oil squeezed out; this escapes through the sides of the hogshead, the hoops not being at first very tightly driven. The cask is filled up three times before the pressing is finished, and then, after eight or nine days, the hogshead of fish should weigh four hundredweight gross. The average number of fish in each hogshead is 2500, and sometimes as many as 1000 hogsheads have been taken at one haul of the sean. The largest single catch recorded at St. Ives was 5500 hogsheads actually landed, and on that occasion great numbers of fish were lost besides. The fluctuation in the sean-pilchard fishery at St. Ives is very great from year to year; and it would appear remarkable, if the success of the fishery did not almost entirely depend on whether or not the shoals came into that part of the bay where alone the seans can be used. The St. Ives sean-fishery has been unsuccessful for the last four years, less than 10,000 hogsheads having been cured in each of those periods; but in the "Pilchard Circular" issued by Messrs. G. C. Fox & Co. of Falmouth, giving an account of the fishery season of 1877, it is said that "considerable bodies of fish visited the coast, but did not come into the stems where seines might have inclosed them."[2] The pilchards cured by the sean owners at St. Ives are all sent to the Italian markets;[3] and we have to thank Messrs. Fox for the preceding statistics of shipments since 1815. The fluctuations are almost entirely due to the variations in the great sean fisheries.

The special sean fisheries for mackerel are along the Chesil Beach near Portland, and on the Sussex coast, at and near Brighton; but they do not call for particular notice.

Stow-net fishery.

Sprats.

Stow-net Fishery.—This fishery appears to be entirely confined to the Solent, inside the Isle of Wight, the estuary of the Thames, and the Wash, between the Norfolk and Lincolnshire coasts. It is specially for the capture of sprats, although many young herrings are sometimes caught, and it is worked most extensively at the entrance of the Thames. The stow-net is a gigantic funnel-shaped bag having a nearly square mouth, 30 feet from the upper to the lower side, and 21 feet wide. It tapers for a length of about 90 feet to a diameter of 5 or 6 feet, and further diminishes to about half that size for another 90 feet to the end of the net. The whole net is therefore about 180 feet or 60 yards long. The upper and lower sides of the square mouth are kept extended by two wooden spars called "balks," and the lower one is weighted so as to open the mouth of the net in a perpendicular direction when it is at work. The size of the meshes varies from an inch and three-eighths near the mouth to half an inch towards the end, where, however, it is again slightly enlarged to allow for the greater pressure of the water at that part. The mode of working the net is very simple. Oyster smacks are commonly used in this fishery, although shrimping boats are also employed in it in the Thames. The smack takes up a position at the first of the tide where there are signs of fish, or in such parts of the estuary as are frequented by the sprats during that part of the season; she then anchors, and at the same moment the net is put overboard and so handled that it at once takes its proper position, which is under the vessel. It is kept there by a very simple arrangement. Four ropes leading, one from each end of the two balks, and therefore from the four corners of the mouth of the net, are united at some little distance in front, forming a double bridle, and a single mooring rope leads from this point of union to the vessel's anchor; so that the same anchor holds both the vessel and the net. The net is kept at any desired distance from the bottom by means of two ropes, one from each end of the upper balk to the corresponding side of the smack, where it is made fast. The open mouth of the net is thus kept suspended below the vessel, and the long mass of netting streams away astern with the tide. The strain of this immense bag-net by the force of the tide is often very great, but if the vessel drags her anchor, the net being made fast to the same mooring, both keep their relative positions. Here they remain for several hours till the tide slackens, the vessel's sails being all taken in, and only one hand being left on deck to keep watch. The way in which the fish are caught hardly requires explanation. The sprats, swimming in immense shoals, are carried by the tide into the open mouth of the net and then on to the small end, where they are collected in enormous numbers; from this there is no escape, as the crowd is constantly increasing, and they cannot stem the strong tide setting into the net. The first thing to be done in taking in the net is to close the mouth, and this is effected by means of a chain leading from the bow of the vessel through an iron loop in the middle of the upper balk down to the centre of the lower one, and by heaving in this chain the two balks are brought together and ultimately hoisted out of the water under the vessel's bowsprit. The net is then brought alongside and overhauled till the end is reached, and this is hoisted on board. The rope by which it is closed having been cast off, the sprats are then measured into the hold of the vessel by about three bushels at a time, until the net has been emptied. The quantity of sprats taken in this manner by many scores of fishing craft during the season, which lasts from November to February, is in some years simply enormous; the markets at Billingsgate and elsewhere are inundated with them, and at last they can only be disposed of at a nominal price for manure; and in this way many hundreds of tons are annually got rid of. The stow-boats do not generally take their fish on shore, but market boats come off to them and buy the fish out of the vessel's hold, and carry it away. The mode of working is the same in the Solent and the Wash as that we have described in the Thames and large quantities of sprats are landed by the Southampton boats.

---

[1] Previous season's fish.

[2] It is difficult to suggest any satisfactory explanation of the fact, that, though large shoals of pilchards are every year observed passing the north coast of Cornwall, it is only in particular years that any great numbers of these fish enter St. Ives Bay and come within reach of the seaners. It might seem that the streams, containing drainage from mining works, which fall into the bay, would pollute the water, and tend to turn back the fish, but there is much less mining in the neighborhood now than formerly. The fishermen's idea that the state and direction of the tide, when a shoal of fish is near the entrance to the bay, affect the course of the shoals appears more plausible, for it must be remembered that, though the fishery season lasts several months, it is only at intervals that the nets are put into the water, and the tide may be unfavorable when the fish are heading towards the bay. It is quite clear that, as the sean fisheries of 1871 and 1873 were the most successful on record, there has been no gradual diminution of pilchards from over-fishing.

[3] A fishery for pilchards has recently been established along the coast of Galicia, and Spanish pilchards, cured in the same manner as the Cornish fish, are making their way in the Italian markets.

White-bait.

"Whitebait," or young herrings, as they should properly be called, are caught in the Thames by a net which is practically nothing else but a very small stow-net, and it is worked in essentially the same manner.

Line fisheries.

Line Fisheries.—Hand-lining and long-lining are worked more or less all round the British Islands, and various kinds of fish, such as cod, haddock, whiting, coalfish, pollack, bream, and conger are taken regularly on the English coast, some being more abundant in one part and some in another. The cod fishery in the North Sea, however, is the one specially deserving notice; it has been carried on in a systematic manner, and on rather a large scale for a great number of years. Welled smacks were in use at Harwich as early as 1712, and in them the cod were brought alive into port just as they are at the present day. The idea of keeping the fish alive appears to have been taken from the Dutch fishermen, and in the interval between 1712 and 1715 three vessels fitted for that purpose were built, but very inferior to those afterwards constructed.[1] In the year 1720 the number had increased to 12, and in 1735 to 30. Of that number Mr. Nathaniel Saunders, the progenitor of several generations of fish-factors and salesmen at Billingsgate, had six, and with four of these, which were very superior to the other two, he visited the coast of Scotland in the course of his fishing expeditions, and was at that time the chief medium for conveying goods to and from the north of Scotland. In 1766 a Mr. Orlibar, a fishing smack owner at Harwich, made the first attempt to fish for cod with long lines on the Dogger Bank; and although he was at first very unsuccessful, he persevered, and was so fortunate that in 1774 the number of smacks had increased to 62, of which 40 went regularly to the Dogger to fish with long lines. In 1788 there were 78 smacks, and in 1798 the number had increased to 96. About this time a few attempts were made at Gravesend, Greenwich, and Barking to construct smacks of a similar description, and the Harwich fishery gradually declined. Afterwards the three places on the Thames increased their connection with this fishery, and Barking especially became an important station, not only for cod-boats, but also for trawlers. Many cod vessels were likewise owned at Gravesend and Greenwich, and these two towns for many years had stores of live cod in chests floating in the river. Great changes have, however, taken place in recent times; the Thames water became so impure that the cod could not be kept alive in it for many days, and ultimately the storing of the fish there was altogether given up. The Harwich river was still used for that purpose, and is so now, although there are but few cod-boats belonging to the place; but the opening of the railways on the east coast gradually brought Grimsby into notice, and its position in relation to the fishing grounds was found so convenient that it gradually became, and there is every reason to believe it will remain, the headquarters of the North Sea cod fishery.

North Sea cod fishery.

The special feature in this fishery which distinguishes it from all other line fishing on the coast of the United Kingdom is the systematic use of welled vessels, in which the cod are kept alive until they are brought into port. These welled smacks are built for the purpose, the well not being a tank fitted into any suitable vessel, but a part of the original construction of the hull. Two strong water-tight bulkheads are built entirely across the vessel from keelson to deck, enclosing a large space just in the centre of the smack. This is the "well;" and a constant supply and circulation of the water from the sea is kept up within it through large auger holes bored in the bottom of the vessel, in that part of it between the bulkheads. The vessel is in fact built in three compartments, and the water has access to the central one through the holes made at the bottom of it. The entrance to the well is on deck through a hatchway, the four sides of which are carried down for about three feet to what is called the well-deck, above the level of the water-line, extending all round the hatchway to the bulkheads and sides of the vessel. The object of this lower deck is to keep the level of the water within certain limits when the vessel is rolling about or pressed down under sail. The cost of these welled smacks is about £300 more than that of the ordinary "dry-bottomed" vessels of the same size. The working expenses of a cod smack are also much heavier than in a trawler. Each of these line boats carries from nine to eleven hands, of whom as many as six or seven are apprentices of various ages; and the system of payment by shares, so general with the trawlers, is here only adopted in the case of the captain, who gets 9 per cent. of the proceeds of the voyage, the mate receiving 24s. per week, the men 22s., and the apprentices from £5 to £12 a year, according to their length of service. Provisions are found by the owner, entirely or nearly so. Both hand lines and long lines are used in this fishery, depending on season and locality. A complete set of long lines consists of about fifteen dozen, or 180 lines, 40 fathoms in length, each supporting 26 hooks on smaller short lines called "snoods," which are fastened to the main line a fathom and a half apart. A "string" of lines of this description is 7200 fathoms long, or nearly eight miles, and has 4680 hooks. Whelks or "buckies" are always used for bait where they can be procured in sufficient quantities, and in the regular long-line season each smack takes about 40 wash[2] of whelks with her for the voyage, and about half that quantity as the season draws to a close in March. The whelks are preserved alive in net bags, and are kept in the vessel's well till wanted, when the shells are broken and the tough fleshy animals extracted. Baiting the large number of hooks used gives plenty of employment to the large crew of the smack. The lines are shot at sunrise or earlier if the weather is fine and there is light enough to see what is being done. The smack is put under easy sail, and kept as much as possible with the wind free, so long as a course can be sailed across the tide, which is important, as then, as the line is paid out, the snoods drift clear of it. The lines are neatly coiled, and with the baited hooks are laid in trays all ready for running, each tray containing from 12 to 16 pieces of line, and as the vessel sails slowly along, the whole length of line is gradually put overboard. A small anchor at every 40 fathoms keeps the line steady on the ground, and its position at the two ends and at every intermediate mile is marked by a conical buoy or "dan," with a staff passed through it and carrying a small flag. When after a few hours the tide has nearly come to an end, the smack, which meanwhile has been hove to in the neighborhood of the last buoy, gets the end of the line on board and works in short tacks along its course, the line being hauled in, and the fish taken off the hooks as she proceeds. When the wind is very light a boat is used for hauling in the line, and the fish are kept alive in the stern of the boat, which is partitioned off so as to form a water-tight division. In any case the strong and lively fish are transferred as soon as possible to the ship's well, and dead fish, or those which do not appear likely to live in the well, are stowed away in ice. The season for long-lining is during winter, and the fishery is carried on both on the Dogger Bank and on well-known ground off the coast of Norfolk. In April this fishery comes to an end, and a few of the smacks go away hand-lining to Iceland and the Faroe Islands, salting the fish they catch there, and usually landing it at Shetland. In July hand-line fishing for cod begins in the home waters, and is continued till October, the commencement of the long-line fishery of which we have just spoken. The July fishery is at a distance of from 10 to 30 miles from the coast, as the approach of the herrings to the land at that time causes a great gathering of cod in their neighborhood. The smack is hove to when hand-lining, and each man works with a single line furnished with from two to six hooks. On the return of the vessel to Grimsby after a few days, the fish are taken out of the well by means of long-handled landing nets, and are put into wooden chests which are kept floating in the fish-dock. These chests are 7 feet long, 4 feet wide, and 2 feet deep, and are constructed so that there is a free circulation of the water through them. The water in the dock at Grimsby being quiet, the chests are made with the ends square; but at Harwich, another storing place for live cod, the chests are moored in the tideway, and have the ends boat-shaped, so as to offer less resistance to the stream. There are about 400 of these chests in use at Grimsby during the height of the cod season, and as many as from 15,000 to 20,000 live cod in them at a time. There is a great advantage in thus storing these fish, as they can always be sent quite fresh to market, and only as many forwarded as there is a demand for. Killing the cod for market is a strange scene, and it goes on daily during the season. Each chest will hold from 40 to 100 cod according to their size, and when the fish are wanted, a chest is hauled alongside a hulk kept in the dock for the purpose, and hoisted up just clear of the water; the top is then opened, and a man steps into the chest and lifts the fish out, seizing them by the head and tail, and throwing them on the deck of the hulk. It is often difficult work to get hold of the struggling and slippery cod, but one after another they are taken out and handed over to the executioner on the deck of the hulk; he grasps the fish tightly behind the head with his left hand, holding it down on the deck, and giving a few heavy blows with a short bludgeon on the nose, kills it at once. The dead fish rapidly accumulate in a heap, whence they are taken on shore to be packed in bulk in the railway trucks waiting by the side of the market to receive them. The fish thus killed and packed reach Billingsgate early the next morning, and are known in the trade as "live cod;" they fetch the highest prices; and there is something in the manner in which they are killed which enables them to be properly crimped many hours after their death.

---

[1] Our notice of the early history of the cod fishery as carried on from Harwich is taken from a statement prepared by Mr. Groom of Harwich, and given to the Royal Sea Fisheries Commissioners in 1864.

[2] A wash is a stamped measure capable of holding twenty-one quarts and a pint of water.

SCOTCH FISHERIES.

SCOTCH FISHERIES.—The important fisheries on the coast of Scotland are drift-fishing for herrings, and line-fishing for cod, haddock, ling, and some other kinds. Besides these there is in particular localities sean or "trawl" fishing for herrings, and for sprats or "garvies."

Herring fishery.

Herring Fishery.—We will first speak of this special fishery, which from its profitable character, extensive range, and the employment it gives to vast numbers of the coast population, both afloat and on shore, ranks as one of the most important fisheries of the United Kingdom, as it is also one of the great harvests of Scotland.

Herring season.

The herring season on the Scotch coast does not commence everywhere at exactly the same time, although the principal fishing is always during the summer months, the winter fishings being local and rather uncertain. The earliest herrings are taken on the west coast, and are generally first met with outside a line between the Butt of Lewis and Cape Wrath during April. In May the herrings come into the Minch and work their way southwards; but they sometimes enter the Minch at the south end of the islands, and in 1870 in particular, there was a large fishery near South Uist and Barra, but mostly on the Atlantic side, some miles south-west of Barra Head. It is rarely, however, that herrings are taken on the western side of the outer Hebrides, and the great fishery may be said to lie between those islands and the mainland. The fish remain in these waters in greater or less abundance till nearly the end of September, but May and June are the most productive months of the season, and during that period a great number of boats from the east coast go to the western side to take part in this early fishery. As July approaches the order of proceeding is reversed: the time is near for commencing the great fishery on the east coast, and one by one the boats which had come from that side return to their own waters, and many others from the western districts accompany them. The eastern fishery begins about the middle of July, and continues until about the end of September, commencing at the north and extending gradually southwards as the season advances. Many changes in the importance of particular districts as centres of this fishery have taken place in the course of years. For a long time Wick was the leading fishing and curing station on the east coast, sending out 1000 boats daily during the best of the season; but recently the fisheries from Peterhead and Fraserburgh have been unusually successful, and they have taken the principal position on the east coast for the extent of their curing operations.

Nets and boats used.

Drift-fishing is the method by which most of the Scotch herrings are taken, the use of seans or "trawls" being practically confined to a few localities on the west coast so far as regards the herrings, although they are employed on the eastern side for the capture of garvies. Cotton nets are now universally used, and the manner of working them is precisely the same as we have already described in our account of the Yarmouth fishery; but there has been a considerable increase in both the size and number of the nets worked by each boat. This has been due to several causes. The lightness of cotton nets compared with those of hemp formerly in use enables a larger quantity of netting to be easily handled by the same number of men, and thus more catching power is provided. Then it is desirable to make up a certain weight of nets in proportion to the size of the boats, that they may not drift too fast and drag the nets through the water; for all the strain that is needed on a fleet of nets is as much as will keep them extended in as near a straight line as may be. The fisheries have in late years been carried on far out at sea, and a remarkable change from open to decked fishing boats has taken place, a change that had for a long time been earnestly recommended to the fishermen for their own sakes, and to prevent the great loss of life which had so frequently occurred when the open boats were overtaken by bad weather. This change led to larger boats being built, capable of using an increased quantity of fishing gear. There are thus many reasons for the additional netting now generally employed, without resorting to the idea that it has become necessary owing to herrings having gradually diminished in the seas. We may here mention that the official returns of Scotch fishing boats have of late years shown a steady diminution in their number, but it will be found on examination that the falling off has been only in the second and third class boats, and that those of the first class have been increasing. In the last report issued by the Board of Fisheries, that for 1876, a decrease of 109 boats is recorded; but at the same time it is stated that there were 181 fishermen and boys more than in the previous year, and the estimated value of the boats, nets, and lines, had increased by as much as £35,719. The size of the fishing boats is limited unfortunately by the general absence of natural deep-water harbors where they would be most useful, so that no very great increase in their tonnage can be conveniently made; and although first-class boats are taking the place of those which were in the second, the change does not involve an addition of more than four or five tons in one of the larger craft. Fourteen tons was a common size for a large second-class boat, and as anything over 15 tons ranks in the first class, the new ones of 17 or 18 tons are all included under that head. There is little difference at first sight in the appearance above water of most Scotch fishing boats, but there are many distinctions below the water-line in accordance with local ideas. As a rule, excepting on parts of the west coast, the boats are sharp at both ends and have a great deal of beam, but they differ much in depth and in the extent of rise to the floor. The Buckie boats have long been remarkable for their peculiar build and rig, having a low and broad midship section with a flat or rather hollow floor; they are very fine at both ends, and have considerable rake of both stem and stern post. They are commonly known as "scaffy" boats. Another peculiarity in these boats was that they carried a mizen lugsail in addition to the large fore and main lugs which were the usual working sails of the general run of Scotch fishing craft. Fishermen as a class are most unwilling to make any change in their style of boats or methods of fishing; but when decked boats were fairly tried on the Scotch coast, their advantages could not fail to be acknowledged; and as it was found that profitable fishing[1] could be carried on with them in weather such as was dangerous for open boats, the change from undecked to decked fishing boats gradually gained favor, and is now very general. This alteration, however, involved an important change in the rig of the boats in the doing away with the main-lug, a sail which for many years had given a distinctive character to the Scotch fishing boats. In our notice of the Yarmouth luggers we mentioned that when the vessel was fishing, the foremast was lowered on to a crutch on deck, so that the vessel might ride easier and not roll about, as the weight of the standing mast would be likely to make her do. This is the practice with all drift-fishing boats; but in decked boats there is a difficulty in doing this with a second mast, and if it were done there would be so much more hamper upon or near the deck and in the way of the fishermen as to cause much inconvenience. The mainmast has therefore been done away with, and the necessary after-sail is provided by means of a mizen, which, being outside the stern, has plenty of power when wanted, and is out of the way of the fishermen. The fore-lug is made larger than it used to be, so that there is still plenty of canvas, and the general rig of the boats is now just what has been for a very long time adopted by the English fishermen as the most convenient for drift-fishing. Steam-tugs have been advantageously used in towing the fishing boats towards and from their fishing ground; but such a system could hardly be generally applied to the vast fleet of boats which collect in certain years at some of the stations.

---

[1] As evidence of the advantage of using large-decked boats, the following extract from the fishery officer's report from Eyemouth is quoted by the Hon. B. F. Primrose, the energetic and obliging secretary to the Board of Fisheries, in his *Annual Report* for 1876:—"The crews who had large-decked boats, and perseveringly followed out the fishing were successful; while those crews about Berwick and Spittal who were not so well prepared did little good. Many of the Eyemouth and Coldingham boats made from £200 to £300 for the season, several from £400 to £500, and a few from £500 to £700 each. The Berwick and Spittal crews, on the other hand, who fished with open boats and inferior netting, made only from £60 to £120." Evidence to the same effect is given from Anstruther, and similar records have appeared in former reports.

Fluctuations in herring fishery.

The fluctuations in the herring fishing are very remarkable, but they are not more so on the coast of Scotland than on that of Norway and elsewhere. Indeed, Norway and Sweden afford instances unparalleled in Britain of the disappearance of herrings from particular districts, and their return in the most unexpected manner after a long course of years (see p. 234). On the coast of Scotland, the changes which take place in the fishery consist in an increase or decrease at particular districts rather than a total disappearance from any one of them. The most marked failure in recent years is in the Firth of Forth, where the summer fishing has now been given up, only a small winter fishing being carried on. At Wick, also, for a great number of years the most important station on the east coast, the herring fishing has been more or less diminishing, whilst at the same time Fraserburgh, only about 70 miles distant from it, has gradually assumed an unexampled importance. It is true that in 1876 there was an immense falling off in the quantity of fish landed at the latter port, but it was a bad year at almost every station on the east and west coasts, and the almost general decrease arose not from any apparent scarcity of fish, but from the boats being frequently kept in harbor by a continuance of very bad weather during the fishing season, or being unable from the same cause to work their nets when they reached their regular grounds. There is some reason for believing the alleged scarcity of herrings near the land is not so great as has been supposed. Successful fishing many miles out at sea has attracted large numbers of boats from the home waters, and the catches inshore have been consequently much diminished; still the general opinion appears to be well founded that the fish have not entered the firths and lochs in the last few years to the same extent as they used to do. That the fisheries, taken as a whole, have been gradually increasing is shown by the carefully prepared statistics of the Board of Fisheries; and it is desirable to point out that the great increase in the quantity of netting now used is to some considerable extent counterbalanced by the shorter time the nets are in the water; for the boats go long distances to sea, and they have to leave off fishing earlier in order to bring in their fish in good time to the curers. It may appear strange that after the lapse of centuries during which the herring fishery has been regularly carried on, so little knowledge should have been gained of the habits of this valuable fish; but it must be confessed that at the present moment we can say nothing positively about what brings the herring towards the land, why at one time they will "strike" the nets, and at another they will apparently not go near them—in short, what are the particular influences which regulate their movements. Of course, the old idea that these fish come into shoal water in order to deposit their spawn is the one still generally received, and we will not venture to say it is incorrect; but if it be true that the spawning fish come in for that purpose, that cannot be the inducement in the case of the "maties" or fish which show no development of the milt or roe. Yet both these herrings do precisely the same. Mackerel differ from herrings in spawning at the surface, and it has been abundantly proved that their ova float during the whole period of development; still we find that mackerel in full spawning condition, and half-grown fish also, are mixed up in the same shoals at the time when they approach the land. Thus we find the habits of surface-spawners and ground-spawners are alike in this respect, yet the common explanation of the visits of the spawning herring will not apply in the case of the mackerel, or even in that of the "matie." With respect to the causes which induce the herrings to keep near the surface, or to remain at some little depth, a step seems to have been taken in the right direction in the observations now being made of the possible relation of the temperature of the sea to the higher or lower movements of the fish. Good service was done by the late Marquis of Tweeddale when he provided a number of deep-sea thermometers for the use of the fishery officers and fishermen, whose observations are reported weekly to the Meteorological Society of Scotland, and come under the careful scrutiny of the secretary, Mr. Alexander Buchan. It is early yet to expect any definite results from this inquiry, as it has only been carried on for four or five years; but the observations hitherto made point to a high degree of temperature in the sea being unfavorable to fishing, and show that, when the sea is found to be colder in any one district than in that on either side of it, the herrings are more abundant and the fishery is more successful in the colder than in the warmer water. It is also stated that the influence of thunderstorms had been perceptible in each year; and that if a thunderstorm of some magnitude had extended over a large portion of the east of Scotland, good takes of fish might be made on that day, but on the following day few if any fish would be caught over that part of the coast, unless at the extreme verge of a deep part of the sea, as if the fish were retreating thither. Observations on the influence of winds and the temperature of the sea have also been made by the Dutch fishermen; and Herr von Freedon of Hamburg believes, from an analysis of these observations, that a temperature of from 53° to 57° F. is most favorable for the herring fishery, and that the chances of success diminish with higher or lower temperatures. Should these conclusions be confirmed, it is quite possible that the fishermen may be enabled, by a trial of the temperature of the sea at different depths, to determine how far their nets should be sunk to give them a fair hope of a successful fishing, instead of working, as they do now, very much on the chance system, often finding that they have been too high or too low for the principal part of the shoal.

Herring curing.

The important system of curing herrings in the wet state, or, as it is properly called, as "white herrings," is more completely worked on the east coast than on the west. The whole process of curing is carried on under the supervision of the Board of British White Herring Fishery, which was established by the Act, 48 Geo. III. c. 110 (1808), and, with some slight changes in its organization and additions to its duties, has continued its labors to the present time. Its particular duties are to inspect the curing, and to see that the proper regulations are duly carried out; to place the Government brand on the barrels when desired, according to the quality of the cure; to see that the regulations for registering the fishing boats are duly attended to; to maintain order on the fishing grounds; to lay out to the best advantage a special grant of money for improving or building fishery harbors; and to prepare accurate statistics of the fisheries. Many years ago curing according to this system was done at some of the English ports,—hence the word British in the title of the board; but for some little time past "white herrings" have practically only been prepared in Scotland, and the now ordinary name of "Fishery Board, Scotland," fairly expresses the geographical limits within which its duties are performed at the present day. The general out-door work of the board is performed by a body of men who are well known by the title of fishery officers; and it is essential that they should have been brought up as coopers, an important part of their duties being to see that barrels[1] of a proper size and make are used for the packing of the cured herrings, and that they are securely headed and driven before they are sent abroad. The various duties these officers have to perform, and the careful training they have had in them, have resulted in the board gradually obtaining a staff of men by whose intelligence and experience a vast store of information about everything connected with the working of the Scotch fisheries has been collected. Each man is placed in charge of a district of the coast, and the detailed reports they make to the secretary form the basis of the valuable and instructive reports of the Commissioners of the Fishery Board annually presented to Parliament.

---

[1] When the fish are brought on shore from the fishing boats, the quantity is ascertained by a "cran" measure, which should hold 45 gallons of ungutted herrings; each cran of such fish is expected to furnish enough good cured and gutted herrings to fill a "barrel" having a capacity of 37½ gallons,—the difference between the two measures being usually accounted for by the broken fish unsuitable for curing, and the less space occupied by the gutted fish.

The operation of curing the herrings begins as soon as they are landed, and the busy scene which is presented at the large curing stations when this work is going on is well described in the article "Fisheries" in the last edition of the present work:—

"All along the inner harbor, and in almost every street and quay, of the town of Wick, as well as within many large inclosed yards and covered buildings, there are numerous square boxes as big as ordinary-sized rooms, the containing sides, however, being only two or three feet high. Into these huge troughs the herrings are carried from the boats as soon as possible after they arrive. There they are all tumbled in helter-skelter, in a long-continued stream of fish, until the boats are emptied or the troughs are filled. Then come troops of sturdy females of various ages and complexions, each armed with knife in hand, who range themselves around the fishery chambers: the process of gutting immediately commences, and is carried on with such ceaseless and untiring activity that the unaccustomed eye can scarcely follow the quickness of their manipulations. One woman will eviscerate about two dozen of herrings in a minute; and when nearly 2000 of them are working at that rate, with but brief intermission from early morning till the close of day, the amount of disembowelment may be more easily imagined than described. This important process is effected in the following manner. The practitioner takes a herring in her left hand, its back lying in her palm, and inserts the point of her knife into the near side of the neck, bearing well down upon the backbone, and making the weapon protrude a little through the other side. She then gives the knife a turn, and pulling it outwards and upwards, with an opposing pressure of the thumb, she draws forth in the first place the gills, stomach, and intestinal canal, and tosses them into an adjoining barrel. She then inserts the knife a second time, and by a peculiar twitch removes what is called the crown gut or cœcal appendages and liver. There are thus two actions performed, each of which seems to occupy about a second of time. This is the ordinary Scotch practice. The Dutch method is somewhat different. They leave in the crown gut, and so with them a single pull suffices to remove whatever is to be taken away. This latter method is partially followed in this country, as being best adapted for the Continental market, where it is believed that the crown gut has a powerful influence in improving the flavor of the fish, and where the appearance of the herring is held to be injured if it is removed. These fair gutters usually work together in little companies of two or three, so that while one is filling a measure with her gutted fish, another carries them off to be *roused*, as it is called, that is, cast into vats or barrels, then sprinkled with salt, then more herrings and more salt, and next a brawny arm plunged among them far above the elbow, thus mingling them together, and so on till the space is filled. They may lie a longer or shorter time in this state, according to the supply of labor at command, and the immediate necessities of gutting and rousing; but the next usual step in the routine is for a third hand to remove those herrings from the second vats or vessels, and re-salt and pack them carefully, every successive row crossing at right angles that which precedes it. Herrings intended for the foreign market are usually arranged with their backs downwards, while those for the Irish market are preferred when packed flat, or more upon their sides. Each row gets a fresh sprinkling of salt until the barrel is filled. The head of the cask is then laid loosely on, the contents being allowed to settle down, or *pine*, as it is called, for a time,—which they soon do so considerably as to admit of each cask receiving another row or two, with additional salt, before being closed by the cooper. The barrels should then be headed up, tightened in the hoops, laid upon their sides, and placed under cover, so as to be shaded from the sun's rays, which are injurious to the fish. They should also be rolled half over every second or third day, until they are bung-packed; which process, if the after intention is to receive the official brand of the Board of Fisheries, must not be sooner performed than after the lapse of ten free days from the date of capture." Sir Thomas Dick Lauder[1] thus describes the final operations:—"When the pickle has been sufficiently poured off, a handful of salt, if required, should be thrown around the inside of the barrels, and the herrings should be pressed close to the inside of the casks, and additional fish, of the same description and date of cure, should be packed in until the barrel is properly filled; after which it should be flagged, headed, blown, and tightened, and the curing marks scratched upon the sides. The barrel may then have its pickle poured in, and be finally bunged up."

Classes and brands.

The cured herrings are separated into four classes:—"Full," or fish having large milt or roe—in fact, those which are nearly or quite ready to spawn; "Maties,"[2] or fat fish, in which the milt or roe is quite undeveloped; "Spent," or shotten, those which have recently spawned, and consequently are in very poor condition, having neither the fat of the maties nor the roe of the full fish; and "Mixed," consisting of fish of all kinds, or unassorted. For these four classes the Board of Fisheries gives distinct brands, denoting the quality and description of fish in each barrel; but the crown full brand, given only to "full" fish properly cured, is the one in special request. It denotes the finest production of the system of the British white herring cure. Branding is quite optional on the part of the curer; but in any case this method of curing can only be carried on under inspection, and barrels of a particular size must be used for packing the fish in. It is one of the anomalies of the system, however, that although it is absolutely forbidden to use barrels of other than a certain specified size, there is not the slightest restriction as to the quality or condition of the fish to be packed in them, so long as the Government brand is not desired for them. Any refuse fish may be cured and packed, but the barrel must be of a certain size. The advantages or disadvantages of the branding system have been often discussed, and it has been frequently condemned as opposed to the general policy of making the sale of an article dependent on its merits alone; it has been contended that the Government is not justified in giving a certificate of the quality of cured herrings more than of any other manufactured article, and in no other case would such a guarantee be given. To this it is replied that there is a demand for "white herrings" in numerous and distant European markets; that without the Government brand a barrel of herrings would in some places rarely be sold unless the contents were first examined; and that the disturbance and exposure of the fish would lessen their value when they were ultimately unpacked at the end possibly of a distant journey. They may pass through many hands before they finally reach the consumer, and each person would be anxious to satisfy himself of their quality. There is no doubt that the brand facilitates the sale under such circumstances, but at the same time it cannot be disputed that thousands of barrels are sold on the Continent every year with no other guarantee than that of the curer's name. Up to the year 1859 no charge was made for branding; but since then a fee of fourpence per barrel has been paid, and the proceeds practically count against the expense of the board. It was believed in some quarters that the alleged value of the brand was really not so great as to make the curers willing to pay for it, and consequently the system might be quietly got rid of by the curers ceasing to make use of it. The result has been precisely the reverse; and the argument against the continuance of branding on the ground of the expenses in connection with it has been considerably weakened by the fact that the system is now to a large extent self-supporting.

The following table shows the amount of fees collected in the years 1859–77, in accordance with the Act 21 and 22 Vict. cap. 69 (1858):—

Year.	Fees Collected.	Year.	Fees Collected.	Year.	Fees Collected.
1859	£2644 12 0	1866	£4158 10 0	1873	£7254 11 6
1860	3865 4 6	1867	5290 7 0	1874	8625 19 6
1861	4422 9 0	1868	3491 0 10	1875	8729 16 6
1862	5578 10 8	1869	4075 7 6	1876	4216 6 6
1863	4614 13 6	1870	4989 13 10	1877	6629 18 4
1864	3623 4 0	1871	5777 4 6		
1865	3613 1 8	1872	7045 10 6		

West coast curing.

On the west coast of Scotland the herring fishery is also of great importance, and, as we have previously mentioned, it begins earlier than that on the eastern side. There is a good deal of curing in the Stornoway district, but the brand is in little favor. It is alleged that the western fish, especially those caught early in the season, are more delicate than those taken on the east coast, and will not bear the close packing requisite for ensuring the proper weight in each barrel if it is to receive the brand. The real explanation is doubtless that the curers are anxious to catch the market as soon as possible, and will not allow the number of days for the fish to be in pickle before sending them away that is necessary according to the branding regulations. These early cured fish are maties or fat herrings, and are chiefly sent to the Russian market. A very large quantity of the western fish caught later in the season is, however, sent to market in the fresh state; they are sprinkled with salt and loosely packed in barrels, and quickly taken by special steamers to Glasgow and to Liverpool. These fish are given under the head of "bulk" in the published returns by the Fishery Board, and, being slightly salted, are included among the "cured fish," although not with those which have been gutted and have gone through the regular preparation for export. On arrival at the home markets they may be readily sold as fresh herrings, after the sprinkling of salt has been washed off.

---

[1] *Directions for taking and curing Herrings, and for the curing of Cod, Ling, Tusk, and Hake*, by Sir Thomas Dick Lauder, Bart., Edinburgh, 1846.

[2] "Maties" is a corruption of the Dutch *maatjes*, the term applied, to herrings in which the roe is small or undeveloped. Its signification, however, is doubtful, and the nearest approach we can find to the word is *maatje* (*klein maat*), a small measure which it seemed might possibly refer to the small size of the undeveloped milt or roe, as compared with the bulky proportions of those organs in the full fish. But our inquiries on the subject from authorities, both in England and the Netherlands, have failed to elicit any definite explanation. The Dutch separate their herrings into three classes, as we do, according to the condition of the reproductive organs, viz:—"Voll," full of roe; "Maatjes," with the roe undeveloped; and "Ylen," empty or shotten. *Maatjes* are generally fat fish, but herrings are in that condition only when the roe is very small. As the breeding season advances, the fat is gradually absorbed, and the fish become *voll;* and when the spawn, then fully matured, is deposited, the herrings are called *ylen*, or empty.

Close time for herrings.

It is on the western coast that the question of a close time for herrings has been so much discussed, and unfortunately in 1860 an Act (23 and 24 Vict. c. 92) was passed by which a close time was established there. The bill was brought in at the instance of some of the curers at Glasgow and other places, principally on the west coast. By this Act herring fishing was entirely prohibited from the 1st of January to the 31st of May on any part of the coast between Ardnamurchan Point and the Mull of Galloway on the south, and from the 1st of January to the 20th of May between Ardnamurchan and Cape Wrath on the north. Not a herring was allowed to be taken during the close season for the purpose of sale, or to be used as bait, or to keep the fishermen from starvation; and it appears that this cruel prohibition was to be enforced that the markets might not be supplied with fish which were not of the best quality, but yet were sufficiently good to command an easy sale, and therefore to lower the prices the curers would otherwise have obtained from the regular summer fishery. It was professed that the early fishing broke up the shoals before they entered the Minch, and therefore diminished the supply in June and July; and it was said that many of the fish caught between January and May were unwholesome and unfit for food. But an inquiry into all the circumstances of the case clearly showed that the promoters of the Act for establishing close time were the curers alone, who held meetings of their own body, and, without consulting the fishermen, pressed forward a measure which sacrificed every one's interest to their own. It was one of the most unhappy episodes in the history of the Scotch fisheries; but fortunately the effects of the close time were soon made known, and after a short experience it was found impossible to enforce a law which brought misery and starvation to the homes of a coast population, many of whom previously could only manage to obtain a bare subsistence by hard and unremitting toil. The law remained practically in abeyance for a time, and no prosecutions for infringing it were carried on pending the result of the report of the royal commission in 1862 on herring trawling. In 1864 this question of close time came also before the royal commission for inquiring into the condition of the sea fisheries generally; and such overwhelming evidence of the evil effects of the close time was brought before the commissioners that, in anticipation of their complete report, they did not hesitate to bring the subject before the Government, with the view to some relief being given before the question could be finally disposed of. This resulted in instructions being given not to enforce the law; and in the following session of parliament a bill was passed by which close time was entirely abolished north of Ardnamurchan Point. This included all the inner and outer Hebrides, where the restriction had been so severely felt. South of that part of the coast close time was continued as before, with the exception of January, which became free to the fishermen. By subsequent legislation (the Sea Fisheries Act, 1868) this close time has been done away with beyond the three-mile limit, so that at the present time herring fishing is entirely free everywhere around the British Islands except within three miles of that part of the coast of Scotland which lies between Ardnamurchan Point and the Mull of Galloway; and the difficulties of enforcing the law there are so great that the close time has now only a nominal existence. Another commission which has been recently engaged in inquiring into the state of the herring fisheries of Scotland has also reported against the utility of close time.

"Trawling" or seaning for herrings. Loch Fyne disputes.

The fisheries of the west coast of Scotland have unfortunately given rise to much bitter feeling among those who are interested in them, either as fishermen or curers, and nothing has caused so much social disturbance as the quarrels between the drift-fishermen and those who have been using the sean-net, or, as it is called in Scotland, the "trawl," for catching herrings. The localities in which these disputes have specially taken place are Loch Fyne and the Kyles of Bute, but more particularly in the former long famous waters. We have already described the general mode of working the sean, when speaking of the English fisheries, and we will only now repeat that this method of fishing consists in shooting a long sheet of netting in a semicircle, both ends of which are most commonly hauled on shore until the whole net with the inclosed fish is landed; but sometimes a boat is used as the fixed point at which the ends of the net are made to meet, and into which the net is hauled as before. In the former case the net is used as a ground-sean, in the latter as a circle-net. Both are equally objected to by the drift fishermen, who, until about the year 1838, had fished Loch Fyne according to the old established method. The trawl was then introduced, and on several occasions a gunboat has been required to keep order between the fishermen when both modes of fishing were being carried on. Loch Fyne, as we have said, was the special scene of these disputes, and one common complaint by the drift fishermen was that the trawls intercepted the fish at the entrance to the loch, and broke up the shoals, so that the herrings did not find their way to the upper water, where it was alleged there always used to be plenty of fish at the proper season. There were complaints also that fish of all sizes were caught by the trawl, those which were too small to be stopped by the drift nets and those too large to be meshed in them—the "mother fish," as some of the fishermen called them. Then it was said that the trawlers sometimes made such enormous hauls that only a portion of the catch could be saved, and, besides other sins laid to their charge, it was finally stated as the crowning offence—one that really explained the principal opposition to the trawlers—that they lowered the price of herrings to a considerable extent by the large supplies they could with little expenditure of time and trouble sometimes throw into the market, and so prevented the driftmen from obtaining the better prices they had commonly got from their smaller catches.

The result of these several complaints was that in 1851 an Act (14 and 15 Vict. c. 26) was passed to put an end to trawling for herrings on the coast of Scotland; but that not proving effective, more stringent measures were brought to bear on the fishermen in 1860 (23 and 24 Vict. c. 92) and 1861 (24 and 25 Vict. c. 72), and fishing with the trawl was completely suppressed. So strong a feeling existed, however, among a large body of the fishermen and others that the complaints against trawling were unjust, and the prohibition injurious to the interests of the public as well as to the fishermen immediately affected by it, that in 1862 a royal commission was appointed especially to inquire into the subject; and in 1864 the question was independently considered by two of the members of the general Sea Fisheries Commission, the third commissioner being purposely absent from the second inquiry, as he had taken part in the proceedings of the previous one. The conclusions arrived at by the two commissions, after hearing a great deal of evidence from both sets of fishermen, were decidedly adverse to the opponents of trawling, and were to the effect that the herring fishery in Loch Fyne had suffered no diminution by that method of working; on the contrary, it had really been progressive, when the periods of comparison were made sufficiently long to correct the annual fluctuations, which were always considerable in this as in all other herring fisheries. They say[1]:—"The selected years of bad fishing, brought as proofs that trawling was destroying the fishery, have, when examined, no application to the question, as an equal number of years of quite as bad fishing are found in every decennial period before the system of trawling had been discovered. . . . Trawling for herring has been an important means of cheapening fish to the consumer, by the large and sudden takes, and has thrown into the market an abundant supply of wholesome fresh fish at prices which enable the poor to enjoy them without having to come into competition with the curer. It is this circumstance which, in our opinion, has produced the demand for repressive legislation, for the gains of the drift-net fishermen are much affected by the sudden and great captures of the trawler, who, working with less capital and with a more productive kind of labor, is able to undersell the drift fishermen, and to derange the market for the curers."

It happened that in 1860, the last year of trawling before its complete suppression, the fishing in Loch Fyne was the largest ever known there; in 1861 it fell off, but in 1862 it was again very large, and that was followed by fluctuations as before, although the drift fishermen then had it all their own way. The recommendations of the two commissions were embodied in an Act (30 and 31 Vict. c. 52) passed in 1867, by which any kind of herring net with what was then the legal mesh was permitted, and trawls so constructed again came into use. By the Sea Fisheries Act, 1868, all restrictions as to the size of mesh were done away, but as that Act only applies to fishing beyond the three-mile limit, the Act of 1867 still regulates the fishing in Loch Fyne. It chanced that from 1868 to 1874 the produce of this loch gradually fell off from 46,813 barrels to 6934 barrels; the herrings did not go to the upper waters of the loch in the same numbers as before, and we need hardly say that the drift fishermen accounted for it mainly by the fact that trawling had again been permitted. The drift fishermen had little belief in the two commissions which had reported that trawling had done no harm; but in 1874, when matters were at their worst, three Scotch gentlemen of position, who were likely to command the confidence of the fishermen, formed themselves into a private committee to inquire into the causes of the failure in Loch Fyne. The result as regards the effects of trawling in keeping away the herrings may be best given in their own words:—"The fact cannot be explained away that the fish seem to be at present disinclined to enter other narrow waters where trawling is unknown."[1] The idea, however, that the opinions of these gentlemen would be received with respect has proved to be a mistaken one; and the fact that three inquiries had resulted in the same conclusions seemed only to make these fishermen the more determined to clamor against trawling. In 1877 a fourth commission was appointed; its object was to examine into the condition of the Scotch herring fisheries generally, and the state of the Loch Fyne fisheries was therefore once more investigated. Yet, notwithstanding that the produce of this loch had increased from 6934 barrels in 1874 to 15,097 in 1875, and to 34,471 in 1876, with a further increase in 1877, so far as the returns had been made up at the time, all the old statements were again brought forward by the drift men. But the facts against them appear to have been too strong, and this last commission, like the three previous ones, has declined to recommend that trawling should be suppressed.

---

[1] *Report of the Royal Sea Fisheries Commissioners*, p. 43 (1866).

Average produce of Loch Fyne.

There is abundant evidence in the records for a great number of years that the annual produce of Loch Fyne has been subject to large fluctuations. But if we compare successive periods of ten years each we shall find that not only are the average total catches in recent years far in excess of those in earlier times, but the average for each boat has very largely increased. The following official record for periods of ten years is very instructive:—

Period.	Average No. of Boats.	Average No. of Barrels.
1827–1836	300	3,469
1837–1846	350	7,388
1847–1856	396	19,949
1857–1866	558	33,096
1867–1876	479	25,561

The average for the ten years 1857-66 was much raised by the enormous catch of 79,893 barrels in 1862, whilst the small number of 6934 barrels only being taken in 1874 has materially lowered the average for the last ten years.

Produce of west coast of Scotland.

If we now look at the produce of the fishery on the whole west coast of Scotland for the last thirty years, taking the average in periods of ten years as before, we find the following:—

Years.	Average Catch.	Highest Catch.	Lowest Catch.
1847–1856	85,837	109,806	56,206
1857–1866	122,154	173,827	83,218
1867–1876	156,988	226,037	83,892

The quantities here given are in barrels, as usual; and the figures in this and the preceding return are taken from the statistics carefully prepared by Mr. George Reiach, assistant inspector under the Board of Fisheries, and furnished by him to the commission in 1877. He had been 27 years in the service of the board, and for the last 14 years the whole of the west coast fisheries had been under his inspection.

Annual returns of herrings.

There is nothing that enables us better to understand the actual condition of a fluctuating industry like our sea fisheries than accurate records of its annual produce. In this respect Scotland, owing to the careful labors of her Board of Fisheries, is in a far more fortunate position than either England or Ireland; and the following tables taken from the last report of the Fishery Board will readily show, by the comparison of any two selected series of years, the gradually increasing importance of the Scotch herring fishery, notwithstanding the fluctuations arising from unfavorable weather and other natural causes. We may add that considerable quantities of herrings which are sold in the local markets and consumed whilst quite fresh, do not appear in the board's returns, but those which are slightly salted for transit by ship to the great markets are so included. The quantities are in barrels, as before.

ABSTRACT showing the total quantity of White Herrings cured, branded, and exported, year by year, *in so far as brought under cognizance of Fishery Officers*, from the 1st of June, 1809, to the 31st of December, 1877; distinguishing the export to Ireland, to the Continent, and to places out of Europe. The periods for which each Return is made end on the 5th of April down to 1844; from that year to 1852, on the 5th of January; and afterwards on the 31st of December; hence two returns were published in 1852. There were no returns for England after January, 1850, or for the Isle of Man after January, 1869.

Periods.	Total Cured.	Total Branded.	Exported.			Total Exported.
			To Ireland.	To the Continent.	Out of Europe.

N. B.—In the six years ending 5th April, 1815, the bounty on herrings cured gutted was two shillings per barrel, while there was a bounty at the same time of two shillings and eightpence per barrel, payable by the excise, on the exportation of herrings, whether cured gutted or ungutted, but which ceased on the 1st June, 1815; in the eleven years ending 5th April, 1826, the bounty on herrings cured gutted was four shillings per barrel; in the four succeeding years the bounty was reduced one shilling per barrel each year till the fifth of April, 1830, when it ceased altogether, and has not since been renewed.

Garvie fishing.

Garvie or Sprat Fishing.—This is carried on to some extent at the upper end of the Firth of Forth, and in the Beauly Firth. In the former locality the garvies are caught by means of trawls (seans), and the principal fishing is on the western side of Inchgarvie. In the Beauly Firth drift-nets are used, and only fish of fair size are taken. Complaints have long been made in both places of the capture of young herrings with the garvies, and the herring fishers have done their best to get the garvie fishery put a stop to; but fortunately they have not succeeded, for this fishery gives profitable employment to a good many fishermen, and there is not a particle of proof that the herring fishing farther out has suffered from the occasional capture of young herrings with the garvies. Sprats are not in much demand in the Scotch markets, and almost all that are taken in the localities mentioned are sent by rail to London. We are sorry to say that the old fallacy of the sprat being nothing but a young herring still prevails among some of the fishermen and curers.

---

[1] The Report of these gentlemen is given in full and ably discussed in the *Annual Report* for 1875 of the Board of Fisheries.

Line fisheries. *Line Fisheries.*—The capture of cod, haddock, ling, and saithe or coalfish is general around the coast of Scotland; and the tusk or torsk, a northern species of the cod family, and in shape like a short-bodied ling, is taken in some numbers at the Shetlands, and a few at the outer Hebrides. Long lines are in use for haddock, ling, and tusk, and also for cod on many parts of the coast; but at the Shetlands hand lines are employed for cod and saithe, and also at Faroe and Iceland. At Newhaven, Eyemouth, and other places in the neighborhood in the Firth of Forth, two sizes of long line are regularly worked in the proper season. The smaller or haddock lines have from 800 to 1000 hooks each, or even more, on snoods 14 inches long and 2½ feet apart, and mussels and lug worms are used as bait. Some little interest is attached to the state of this fishery, as it is an important one in Scotland, and a few years ago it was said to have fallen off very much. But it appears there are still plenty of haddocks on the coast, and now that larger and decked boats are used, and the fishermen are consequently more independent of weather, very large takes are not uncommon. In one week in January, 1876, the Eyemouth boats were at sea six times, and landed 20,000 stones of haddocks, which sold at 2s. per stone, producing in that short period no less than £2000. The season lasts here from October to April, and the average gain for the season by each boat usually ranges from £400 to £600. There is a considerable trade in smoked haddocks, particularly from Eyemouth, and the curing consists in soaking the fish in pickle for half an hour, and then hanging them for about four hours in some hardwood smoke. The village of Findon, between Stonehaven and Aberdeen, has long been famous for first preparing the fish known as "Finnan haddies." Their peculiar flavor, which has made them so popular, arises from their being hung in peat smoke. They are cured in the cottages, and some little variation in the time in pickle and in smoke is made according to the time they are intended to keep. This manufacture is now carried on at many places besides Findon. The cod or "great lines" are of the same description as those used for haddock fishing, but have longer snoods, and the hooks farther apart. It is unnecessary to speak of the manner in which these long-lines are worked, as we have fully described it in our notice of the North Sea cod fishery. A vast quantity of line fish is sent to the fresh market, but the great importance of this Scotch fishery is due to the large extent to which curing operations are carried on, and more especially in the distant districts such as the Shetlands and the outer Hebrides.

Curing of cod, etc. Curing is performed in two ways—dry and in pickle. The latter method consists in packing the fish, after they have been split open, gutted, and part of the backbone and the head removed, with layers of salt in barrels; but when to be cured dried, these fish, perhaps caught as far off as the Faroe Islands or Iceland, and landed at the Shetlands, are unpacked, washed, and spread out either on stages or on the beach, and exposed for some days to the air and sun, due attention being given to them to ensure their being evenly dried. When thoroughly cured, they are kept in a cool dry place, until wanted for shipment. The fish caught near the coast are salted as soon as landed, and afterwards treated as the others. The produce of the Shetland fishery is large in itself; but the return of fish cured in those islands is greatly increased by the supplies of fish in pickle landed there for curing by the Grimsby and Shetland smacks, which go every year to Faroe, Iceland, and other more or less distant fishing grounds.

A great deal of the cod and some of the ling go to the Spanish markets and a little to Australia; but the ling and tusk are chiefly sent to Dublin, Glasgow, and Leith, and the saithe to Belfast, Leith, and Dundee.

In 1877[1] the number of fishing boats in Scotland was 14,623, and of fishermen and boys 45,890, and the estimated value of the boats, nets, and lines employed in the herring and cod and ling fisheries was £1,178,412, being an increase over the numbers for 1876 of 76 boats and 627 fishermen and boys, and also an increase of £50,418 in the estimated value of boats, nets, and lines.

ABSTRACT showing the Total Quantity of Cod, Ling, Hake, Saithe, and Tusk, cured and exported, year by year, *in so far as brought under cognizance of Fishery Officers*, from the 10th of October, 1820, when the system for encouragement and improvement of the Cod and Ling Fishery commenced, to the 31st of December, 1877. The periods for which each Return is made end on the 5th of April down to 1844; from that year to 1852 on the 5th of January, and afterwards on the 31st of December. Two returns, therefore, appear for 1852 in the tables. The collection of Returns for England ceased from the 5th of January, 1850, when also the Punching and Branding of Cod and Ling came to an end; and there were no Returns for the Isle of Man after January, 1869.

N. B.—The books of the Fishery Board do not show the total quantity of cod, ling, etc., *cured* till the year commencing 5th April, 1825. The bounty from the earliest date in this abstract to the 5th of April, 1830, was four shillings per cwt. for fish cured dried, and two shillings and sixpence per barrel for fish cured in pickle, taken by the crews of vessels or boats *not* on the tonnage bounty; while the bounty for vessels licensed for the cod and ling fishery, on the tonnage bounty, was fifty shillings per ton, for tonnage and cargo, to the 5th of July, 1826, diminishing five shillings annually to the 5th of April, 1830, when the bounties altogether ceased.

IRISH FISHERIES. IRISH FISHERIES.—After a continuous depression of 30 years, during which the number of boats and fishermen was reduced to less than a third, the Irish sea fisheries showed some indications of an improvement in 1876, the last year[2] for which the inspectors have published their annual report. The difficulty in ascertaining the precise number of boats and fishermen on some of the wilder parts of the coast is so great, however, notwithstanding the important fact that the coastguard is employed in collecting the information, that, as the inspectors tell us, the returns even at the present time cannot be taken as quite trustworthy. There was, however, an apparent increase of 46 craft and 585 fishermen, and this seemed certainly the most encouraging report that had reached us for many years. But an analysis of the return shows that this increase is more apparent than real. The inspectors conveniently divide the boats with their crews into three classes independently of tonnage, and this plan enables us in some measure to understand who are included under the head of fishermen. The divisions come under the following heads, and we give the returns for 1875 and 1876 for the sake of comparison:—

Year.	Solely Fishing.		Mostly Fishing.		Occasionally Fishing.	
	Boats.	Men.	Boats.	Men.	Boats.	Men.
1875	1341	6241	602	1870	3976	14,997
1876	1283	6105	644	2248	4038	15,340

The total number of boats and men in 1876 was—boats 5965, and fishermen 23,693, being a slight increase in both over the previous year. But there is a falling off in the number of regular fishermen, and the increase is only in those who devote part of their time to fishing. We have it on the authority of the inspectors that the men in the third division, or occasional fishermen, are not employed in that occupation on an average for more than one month in the year, and yet we find the boats in this division form more than two-thirds, and the men nearly the same proportion, of the total numbers in Ireland.

---

[1] Report of Fishery Board, Scotland, for 1877.

[2] After the above was in type the Inspectors' Report for 1877 has been published. They state that there has been an apparent decrease of no less than 583 fishing boats and 3300 fishermen and boys since 1876; but, as in previous years, they do not appear to have much confidence in the accuracy of the returns. The herring fisheries were better than in 1876, those for mackerel and pilchards not so good; but the total quantity and value of the herrings, mackerel, and cod consigned to the English markets exceeded those of the year before.

The history of the Irish fisheries shows that great fluctuations have taken place at various times, but the last great decline undoubtedly dates from the period of the famine in 1846, and those who have been long acquainted with the west coast fishermen in particular believe that their present depressed state is entirely the result of that disastrous time. Local assistance has been given time after time with only a temporary improvement; and now the experiment is being tried of advancing money from the Irish Reproductive Loan Fund to enable the fishermen to provide the necessary gear for fishing. The applications for loans have been, as was expected, far in excess of the amount available for the purpose, and in very many cases no security could be obtained that the money would be expended in the manner proposed. No doubt some good will be done by these loans, but much lasting advantage is not to be expected from the system. Emigration has carried off thousands from the country, and mainly from the west coast, where, however, the majority of the fishermen were little more so than in name, and fishing was never allowed to interfere with sea-weed cutting, farming, and any chance occupation. There is this to be said, however, that on very many parts of the west coast of Ireland the weather is frequently so bad, and the seas so stormy that fishing cannot be carried on with any regularity; and when favorable times arrive, the neglected boats and fishing gear are too often unfit for use. On the east and south coasts things are in a better condition; important fisheries for herrings and mackerel in their seasons there provide profitable employment not only for Irish fishermen, but for large numbers of Cornish, Scotch, and Manx fishing boats, which until the last year or two have far outnumbered the native craft. There is plenty of fish to be caught on the Irish coasts; and the influence of the strangers is telling on many of the Irish fishermen, and leading them to improvement in their boats and all that relates to carrying on their work.

The principal methods of fishing in Irish waters are trawling, drift-fishing, and line fishing; there is also a little done with seans and trammels.

Trawling.

Trawling.—Dublin is the headquarters of the deep-sea trawlers, and possesses a fleet of about 50 smacks, ranging from 30 to 50 tons, and working chiefly from that station. Deep-sea trawlers were first used from Dublin in 1818, when, as previously mentioned, some Brixham boats and fishermen were brought over. The fishing was found to be profitable, and the fleet of smacks was gradually increased until it reached its present size. The trawlers work throughout the year when they can get sufficient hands, but the light summer weather is not very suitable for them; and the attractions of the herring fishery and profitable employment on board yachts take away a great many men for several weeks from their ordinary occupation. The principal trawling grounds lie within a triangular space between Dublin and Dundrum Bays and the Isle of Man, and consist of a number of patches differing in shape and extent, which are worked over, either on the inner or outer grounds, according to the season. The Isle of Man ground, lying in deep water, and a favorite place for soles, is usually fished from March to July. In January there is a partial migration of the trawlers to the south of Ireland, and a very productive fishing place known as the Saltee ground, and about south-west from the Saltee lightship, near Waterford, is worked by them with advantage. Farther out at sea, at a distance of 30 or 40 miles from the land, and without any very clearly defined limits, is what has long been spoken of as the Nymph Bank.[1] Extraordinary results have been anticipated from fishing this ground, and no doubt there is plenty of fish upon it; but there are difficulties in working it properly, partly on account of many scattered rocks which interfere with trawling on it generally, and partly because of a want of organization for bringing in the fish and sending them to market. For a long time the greatest difficulty encountered was from the local fishermen, who would not work in a deep-sea trawler, or allow one to use her nets anywhere within the headlands, although the weather was too bad to go outside. Companies have been formed for trawling from Waterford harbor, but the determined hostility of many of the native fishermen, and the fears of others in consequence, have done more to discourage trawling there on a large scale than anything else. English crews have been tried, but it is not surprising that they should be unwilling to remain in a locality where the feeling against them was so strong. Matters seem to have improved of late, but a good deal of enterprise is needed to carry on the fishing in the way in which it might be done. Trawling is worked in the shoaler parts of Waterford harbor by the local fishermen; and the complaint made by them that the large trawlers did so much mischief in destroying the young fry, whilst the small boats habitually worked where the young fish were most abundant, was not too absurd to be listened to by the inspecting commissioner of fisheries a few years ago. A bye-law was therefore established (probably with the object of preserving the peace) to keep the large trawlers beyond a certain depth of water, and the small ones then had it all their own way inside. Under the present more enlightened system of inspection the tendency is happily to remove restrictions to fishing rather than to make them; and the results of a systematic search for spawn in the Irish bays are reported to have been such as to refute completely the charges brought against the trawlers of destroying it.

Drift fishing.

Drift fishing.—Two of the most important fisheries in Ireland are those for herrings and mackerel. That for herrings is carried on more or less on many parts of the coast, but its chief seat is in the Irish Channel, with Howth, the northern point of Dublin Bay, and Ardglass, opposite the Isle of Man, for its headquarters. The fishery begins at the end of May or beginning of June, and lasts well into September, or in some parts into October. By July it is in full work, and the two stations above mentioned are then the scene of unusual life and activity, for a very large proportion of the fish landed there is at once packed and sent off fresh to the English and Scotch markets. A little curing is done at Howth, but it better answers the purpose of the Irish people to send their own fish fresh to market, and to import cured fish from Scotland. The question of introducing the branding system into Ireland has recently been considered by the inspectors of fisheries, and inquiries were held on various parts of the coast in order to find out the general feeling about it. The inspectors say, however, in their report for 1876:—"With regard to branding, we felt it our duty to report that under existing circumstances we were unable to recommend extension of the system to Ireland—there being, firstly, no *bona fide* desire for it existing amongst the Irish fishermen or curers; and, secondly, that the fish caught in Ireland and sold fresh realized a much higher price to the captors than the price received by the fishermen in Scotland and cured for the foreign markets, and that no material benefit would therefore really be derived from such extension."

Ireland is in fact well off in having a market across the channel for any quantity of fresh fish she may send over; and a large proportion of the herrings and trawl fish caught on the east coast, and almost all the mackerel taken in the Kinsale fishery, are at once despatched there. The drift fisheries are, as before mentioned, by no means monopolized by the Irish fishermen, but are taken part in by a large number of strangers. The inspectors in their report for 1876 tell us that "the highest number of boats of each country at Howth during the season was—Cornish 206, Irish 209, Scotch 224, Manx 133. At Ardglass the highest average number that fished during one day (23d July) was —Scotch 140, Manx 20, Irish 42, Cornish 19." These figures show a slight increase in the Irish boats over those in previous years. The east coast fishermen have of late shown many signs of improvement; and the better boats and steady industry of the Manx, Scotch, and Cornish fishermen have not been without their use as examples of how to work the fisheries with profit.

---

[1] Mr. Fraser mentions that in 1726 a proposal was made by Mr. William Doyle, hydrographer, for supplying the large English markets with fish preserved in well-boats, from the southern coast of Ireland, and particularly from a fishing ground he states he had discovered, unto which he gave the name of Nymph Bank, from a vessel called the "Nymph," which he employed in the examination of this fishing ground.—*Review of Domestic Fisheries*, p. 4 (1818).

Kinsale mackerel fishery.

Kinsale has in recent years come into notice as the great station for the mackerel fishery. This fishing begins early in March and goes on till about the end of June, thus immediately preceding the herring season. In 1876 there were 217 English and Manx boats, 13 Scotch, and 133 Irish engaged in this fishery, besides more than 60 large French luggers, the last-mentioned boats salting their fish as soon as caught, and returning home when they have made their cargo. The mackerel fishery is a very important one for Kinsale, as it gives employment, not only to the fishermen, but to numerous other persons of various descriptions. The mackerel are almost all packed in ice and sent to England. During the season of 1876 there were 7 steamers and 11 cutters in this carrying trade,—the former at a monthly expense of £350 to £400 for each vessel, besides paying all dues, coals, and pilotage; and 4400 tons of ice were imported solely for the package of the fish. The mackerel are packed in boxes containing a "hundred," or six score of fish in each, and the official returns show a total capture of 139,083 boxes full in the season of 1876. The prices ranged from 12s. to £5 per box in the course of the regular season; but some boats made a large catch afterwards in July, when there was little demand for the fish, and prices then went as low as 3s. per 100.

Exports of fish from Ireland.

The following is a summary of the quantity of herrings, mackerel, and cod exported from Ireland to the undermentioned places in England during 1876:—

	Herrings.	Mackerel.	Cod.
	Boxes of 2 cwt.	Boxes of 2 cwt.	Boxes of 2 cwt.
London	31,606	29,500	11,882
Nottingham	3,552	2,770	4,829
Bradford	6,977	3,805	3,001
Manchester	17,555	9,721	9.854
Sheffield	7,819	5,583	2,465
Wolverhampton	5,521	4,078	2,098
Leeds	6,998	5,282	2,953
Liverpool	21.763	14,017	12,000
Birmingham	12,204	4.894	5,987
Total	113,995	79,650	55,069

Herrings valued at £2 per box	£227,990
Mackerel,[1] 139,083 boxes at an average of 16s. per box	111,266
Cod at £3 per box	165,207
Total value	£504,463

It will be seen from the above figures that the Irish fisheries are by no means wanting in importance, and it is much to be regretted that the fishermen of the country do not take a larger share in working them. The produce of the deep-sea trawl fishery is also very valuable, but we can give no return of the considerable quantity of trawl-fish sent to England.

Proposed pilchard fisheries.

It has been a matter of surprise to many that no systematic attempt has been made to catch the large shoals of pilchards which annually visit the south coast of Ireland. The prejudice of the Irish fishermen against pilchards has been so great as to almost dishearten the inspectors in their repeated endeavors to bring this fishery into notice. Whilst the great Cornish sean-fisheries have been languishing because the shoals of pilchards have not come into the bays within reach of the nets, they have been in plenty on parts of the Irish coast. One of the inspectors (Mr. Brady) has been untiring in his exertions to procure every kind of information about the catching and curing of pilchards in the Cornish fashion, in the hope of its leading to the establishment of curing stations in Ireland, but little progress has yet been made. The inspectors, however, continue to be hopeful in the matter, and in their report for 1876 they say:—"No efforts have yet been made to cure for the Continental markets, but some have been cured for home consumption on various parts of the coast. By degrees this fish is being regarded with more favor by the country people, and if they continue to frequent our coast as they have now done for some years, there is little doubt but that a considerable trade will result, as they come more into favor."

We have now referred to all the important Irish sea fisheries. It may be added that line-fishing is more or less general around the coast, and is perhaps more systematically attempted on the north and west sides than elsewhere.

MANX FISHERIES.

MANX FISHERIES.—The fisheries carried on from the Isle of Man do not call for special notice, as they are practically those of the Irish sea, and in which the industrious Manxmen always take a prominent part.

British crab and lobster fisheries.

MINOR BRITISH FISHERIES.—*Crab and Lobster Fisheries.*—The demand for these crustaceans has increased so much within the last few years that the supply from the coasts of Britain has been insufficient, and from 400,000 to 600,000 lobsters have for some little time been annually imported from Norway. They travel without much loss in vessels fitted with wells; and for journeys lasting no longer than two or three days they will live very well if packed with wet seaweed in boxes. The places from which the principal home supplies are sent to the large markets being now mostly within easy reach of railways, there is little occasion to use welled vessels for collecting them.[2] The English markets are mainly supplied from Cornwall and the south coast of England, from the Orkneys and Hebrides in Scotland, and from the west coast of Ireland. Besides these, about 200,000 come from France, the fishery for them being in the neighborhood of Cherbourg, and a few from Sweden. The means adopted for catching lobsters and crabs in the British Islands are either circular basket-work "pots" with a mouse-trap entrance at the top, or cages covered with netting and with one or two entrances as in the pots. These cages are commonly called "creels." Crabs are taken in most abundance in the west and south of England, and more or less generally on the east coast, and in Scotland and Ireland, those from parts of Devon and Cornwall being the finest which are sent to market. There is a general disposition on the part of the fishermen to submit to some law limiting the size of both crabs and lobsters to be offered for sale, so as to put a stop to the falling off in these fisheries, which is apparent on some parts of the coast. A close-time is objected to, as no month in the year is generally suitable, and "berried" lobsters are so valuable for the market that if they had to be returned to the sea the fishermen would lose a great part of their present profits. A limit to the size allowed to be sold seems therefore to be the best means of protecting these fisheries; and such a law is now enforced on the coast of Norfolk.

Shrimps and prawns.

Shrimp and Prawn Fisheries.—The most important of these fisheries are carried on in the estuary of the Thames, Pegwell Bay near Ramsgate, and Morecambe Bay on the Lancashire coast, but they are more or less general wherever suitable ground is met with. Leigh is the headquarters of the Thames shrimpers. They fish with a net mounted very much like a beam-trawl, but having a long, straight piece of wood at the lower part of the mouth to work over the ground instead of the ordinary ground-rope. This is, in fact, like the common form of hand-shrimping net, but so fitted as to be towed instead of pushed. Ordinary trawls are used for prawns or "red shrimps," and in some other places for true shrimps. The supply of shrimps from Leigh sometimes amounts to 2000 gallons in a day.

Oyster fisheries.

Shellfish: — Oysters, Mussels, Whelks, Periwinkles.—The oyster fisheries of the British Islands have been in a failing condition for some few years past, owing to a deficiency of spat, the cause of which has been the subject of active controversy, not only between rival theorists, but also among practical fishermen. Over-fishing has been regarded by many as the main cause of the decrease, and it may possibly have helped to make matters worse than they would otherwise have been; but it is difficult to explain in this manner the fact that in England, Scotland, and Ireland there has been a general failure of spat for some years past, on all kinds of ground and under every condition, in public and private beds, and whether they have been carefully protected, as in the case of old established private companies, or left to the working of the general public, except during a definite close-time, more or less enforced. In Ireland, where there are regulations for close-time, and restrictions as to the size of oysters allowed to be sold, and where in some cases all fishing has been stopped for two or three years, the decrease of oysters has been as decided as in England or Scotland;

---

[1] 139,083 boxes of mackerel were recorded, and most of them were exported, but the returns of exports are incomplete.

[2] *Report of Commission on Crab and Lobster Fisheries*, p. ii. (1877).

and Mr. Blake, until recently one of the inspectors of Irish fisheries, and chairman of the oyster commission in 1868, stated in his evidence given before the select committee of the House of Commons in 1876 that the decline in the oyster fisheries was due to the bad spatting seasons, and to the great increase of dredging; "but if the spatting went on as it formerly did, the amount of dredging would not be of much importance."

The bulk of English supplies is obtained from the oyster beds of private companies, of which the Whitstable company is the most ancient, having worked from time immemorial on their present ground on the south shore of the entrance to the Thames. In 1793 they purchased from the lord of the manor the exclusive right of fishing there. The company is a corporation of fishermen governed by elected members of their own body. The men are paid for the daily work done by them, and each member of the company also receives his share of the profits on the sale of the oysters. A great part of their employment, besides dredging and keeping their own ground clean and free from vermin, consists in dredging for spat in the public portion of the river for the purpose of laying it down on their own beds. A general failure of spat, such as there has been in recent years, is therefore not only felt by them on their own limited ground, but they suffer from the scarcity in what may be called their reserves. The Whitstable company is, however, only one among many which occupy the shores of the Thames estuary and the small rivers which flow into it. The oysters thus laid down or bred in these situations become remarkable for the thinness of their shells, and the good flavor and comparatively large size of their contents, and are what are known as "natives." There are numerous companies or individual proprietors engaged in cultivating oysters on various parts of the coast, but at the present time they are, we believe, all more or less suffering from deficiency of spat. Channel or deep-sea oysters are generally large and coarse, and do not fetch more than one-tenth of the price given for the more delicate "natives." Attempts at the artificial cultivation of oysters have not met with much success.

Mussels and whelks.

Mussels and *whelks*, while in some request for food among the lower classes, are in especial demand for the purposes of fish-bait, and the value of mussels in this respect has recently led to a more careful protection of the older banks, and some attempts at the cultivation of new ones. Whelks are particularly valuable in the North Sea cod fishery, and a number of vessels from Grimsby are regularly engaged in fishing for them. Their mode of catching them is by means of shallow hoop-nets baited with refuse fish, and sunk to the bottom on suitable ground. In these the whelks collect in large numbers, and are caught without any difficulty. A considerable supply is also obtained from the oyster dredgers; and at the mouth of the Thames they are caught largely by using "trots" or bulters—long-lines of small dimensions; but instead of having baited hooks, they have common small shore-crabs threaded on the snoods, about twenty on each. These are seized by the whelks, and so firmly held whilst being devoured that the line may be easily hauled in without disturbing the numbers found on every snood. *Periwinkles* are all procured between tide-marks, and are of course collected by hand. The London market is mainly supplied from the western islands of Scotland, the Orkneys, the Shetlands, and parts of the Irish coast.

Periwinkles.

British American fisheries.

British North American Fisheries.[1]—The principal fisheries coming under this head are for cod, herring, and mackerel, including the long-famous cod fishery of Newfoundland The fisheries of the Dominion of Canada are chiefly carried on with open boats, and consequently are to a great extent, though subject to some variation, what may be called shore fisheries. The proportion, as given by Professor Hind, of the shore fisheries to the deep-sea fisheries, in which decked vessels are employed, is 4·4 to 1, so that "by far the largest proportion of the fishing industry of the Dominion is pursued in coastal waters, and much of it rarely extends beyond the limit of three marine miles from the coast line." The following table shows the number of boats and vessels, with the aggregate number of men employed in each, in 1876:—

	Boats.	Men.	Vessels.	Men.
Nova Scotia............	9,585	18,093	653	6,049
New Brunswick........	3,850	7,322	463	1,794
Quebec	5,815	10,777	256	1,219
Prince Edward Island	991	3,831	7	35
Total.................	20,241	40,023	1,397	9,097

In the Newfoundland fisheries boats and vessels are also used, but the deep-sea fishery is scarcely distinct from that pursued in coastal waters, or within the three-mile limit from the shore. The total number of boats employed at Newfoundland in 1874 was 18,611, and the number of persons engaged in catching and curing fish 45,854, while the number of vessels was 1197, with an aggregate of 61,551 tons, and manned by 8394 fishermen sailors. These vessels, however, include the large number used for sealing. The number of "fishing rooms" or portions of the shore set apart for the curing and storing of fish was 8902 in the same year. The numbers of fishing craft, men, and fishing rooms in 1874 showed a considerable increase over those for 1869. Professor Hind, in speaking of the large proportion of inshore fishing, says:—"The changeable character of the weather on the British American coast, the sudden and unexpected occurrence of fogs, the variations of currents produced by tides, the long experience of the dangers attending fishing in open boats some distance from the land, the pecuniary resources of the fishermen, conjointly with the abundant fish resources of the coastal waters, have combined to limit the industry of the British American fishermen in a great measure to the immediate vicinity of the shore line, and within easy reach of harbors. This is particularly the case with Newfoundland." This inshore fishery, however, depends for its success on the supply of bait fishes, especially the capelan and herring; and, as in every kind of fishery, there are years when migratory fish, those which more or less change their quarters at particular seasons, vary in abundance in certain localities, and sometimes forsake one part of a coast and go to another, so the important fisheries dependent on these movements are subject to fluctuations. The cod, in fact, there follow the bait-fishes precisely as, on the English coast, the cod and coalfish become most numerous near the land when the shoals of herrings come closest in. On the coasts of British North America the fishing interest is almost entirely concerned with species whose natural habitat is in cold waters; and as an immense area of fishing water is there influenced by the Labrador current, it is not surprising that cod, holibut, herring, mackerel, and others should be found in abundance on these coasts. The mackerel has also an extensive range south along the coast of the United States; but the Labrador current is little felt south of Cape Cod, its influence being there almost destroyed by the Gulf Stream. The really cold-water species are therefore mainly found in the Dominion seas; and the fact that American fishermen so systematically work there for them is the ground on which the Dominion claim for compensation from the United States Government was based. The sum recently awarded to the colony by the arbitrators is much less, however, than the amount of the claim.

The methods of fishing in use in the Dominion and Newfoundland waters are of the same kind as in the British Islands, with the exception of beam-trawling, which seems to be practically unknown on the American coasts. Herrings are taken by drift-nets, anchored nets, and seans; mackerel by seans and hook and line; capelan by seans; and cod and its allies by long-lines or bulters—there, strange to say, known as "trawls."

Professor Hind states (at p. 58 of pt. 1 of his report) that the aggregate number of barrels of herrings caught in Dominion and Newfoundland waters in 1874 may be put down at—

Dominion waters........................	534,307 barrels.
Newfoundland waters.....................	271,382 "
Total........	805,689 barrels.

This number does not include the quantities used for manure or bait; and he adds:—"A million barrels of herring each year, and gradually increasing, will fairly represent the quantity of this fish taken from British American seas." In the same year 164,879 barrels of mackerel were taken in Dominion waters, of which 80 per cent. were caught on the coast of Nova Scotia. The mackerel fishery at Newfoundland appears to have been very small for some years; and the fishermen do not now seem to be well provided with the means of catching them; but there is reason to believe that this fishery might be largely increased in the Dominion waters if more attention were given to it. There is a very great demand for mackerel in the American market. The Newfoundland and Dominion cod fisheries are, as we have mentioned, almost entirely inshore fisheries, and the abundance or scarcity of capelan or other fishes there used as bait materially affects the success of the fishery, for if the bait fishes do not come inshore, there is no attraction for the cod. In the deep-sea fishery on the banks the case is different; but they are almost neglected by the Dominion and Newfoundland fishermen, for reasons previously stated. The produce of the inshore cod fisheries, although fluctuating, shows no signs of being exhausted. The following table, it is believed, represents with tolerable accuracy the catch of cod and allied fishes on the Dominion coasts in the years stated:—

---

[1] An elaborate and in many respects valuable Report, by Professor Henry Youle Hind, M. A., of the Fishery Commission, Halifax, published so recently as 1877, has largely supplied us with materials for our notice of the fisheries of British North America.

Year.	Quintals.	Year.	Quintals.
1869	730,928	1873	1,405,804
1870	801,553	1874	1,278,499
1871	964,131	1875	1,193,579
1872	1,372,207		

The export of dried cod in quintals from Newfoundland in the years 1869–1876 was:—

Year.	Quintals.	Year.	Quintals.
1869	1,204,086	1873	1,369,205
1870	1,213,737	1874	1,609,724
1871	1,328,726	1875	1,136,235
1872	1,221,156	1876	1,364,068

The British American fishery for lobsters is of some importance, and cod roes and livers are among the valuable articles of export.

The French fisheries at Newfoundland are carried on both on the banks and near the island, the craft employed being of various sizes, ranging from vessels averaging about 170 tons down to open boats. The following table[1] gives the number of craft of all kinds and the total number of men in each year from 1867 to 1874:—

Year.	Vessels, etc.	Men.	Year.	Vessels, etc.	Men.
1867	804	7178	1871	665	5295
1868	774	6552	1872	865	5620
1869	806	6452	1873	899	6036
1870	833	6397	1874	847	5621

Of the numbers of fishing craft here given about 70 per cent. are boats. The produce of the French Newfoundland fishery in 1872 was said to be 10 million francs.

United States fisheries.

UNITED STATES FISHERIES.—These may be divided into warm-water and cold-water fisheries, the latter being for the most part carried on in British American waters. The cod fishery formerly prosecuted off the coast of New England, in the cold water north of Cape Cod, is said to have seriously decreased, and it is believed by Professor Baird, the commissioner of fish and fisheries, that the failure is largely due to the diminution of alewives and other bait-fishes, caused by the numerous dams and obstructions in the rivers in which these fishes were accustomed to spawn. The young fish formerly produced in such myriads are now said to be comparatively few, and the cod and allied fishes consequently have less food to attract them to the old haunts. As there is no reason to suppose that cod, as a species, are diminishing in numbers the conclusion obviously is that they are seeking other feeding grounds. The warm-water fisheries include the pursuit of a variety of fishes, but the "scup," a kind of bream, and the "blue-fish," both migratory species, are those whose capture is thought of most value. Although almost all the shore fisheries are said to be decreasing,[2] Professor Baird, in his elaborate reports to the United States Government, does not seem to be quite clear as to an effectual remedy. The pounds and weirs are said to be very destructive to spawning fish, but they supply a large quantity of fish to the markets. The scourge of the American coast appears to be the blue-fish, "destroying ten times as many fish as they really need for food, and leaving in their track the surface of the water covered with the blood and fragments of the mangled fish."[3] Professor Baird estimates that in 1871 there were 100 millions of these fish on part of the American coast, and that each one destroyed twenty fish per day; and as the blue-fish season lasts from 120 to 150 days, some idea may be formed of the extent of the mischief caused by them. Fortunately the blue-fish is in great request as an article of food, and about a million and a quarter were captured in 1871, or, as estimated, one in a hundred of those on the coast. To the blue-fish Professor Baird assigns the very first position among the injurious influences that have affected the supply of fishes on the coast. The agency of man he places next,—the pounds and weirs along-shore catching spawning-fishes, and the dams and other obstructions in the rivers preventing certain species from ascending to their proper spawning grounds. He proposed to limit the working of the pounds and weirs to a certain number of days in each week, and to do away as much as possible with the river obstructions. The blue-fish is beyond control.

The estimated value of the United States sea fisheries in 1876 was—

Warm-water fisheries	$3,274,138
Cold-water "	9,756,683
	$13,030,821

The comparative value of the cold-water fisheries of the United States and of British North America for the years 1870–6 is shown in the following table[4]—the greater portion of the value in the United States return being from fish caught in British American waters:—

Year.	United States.	British North America.
1870	$5,313,967	$14,260,298
1871	11,482,410	16,086,081
1872	9,526,647	16,524,644
1873	8,348,185	18,793,953
1874	9,522,553	20,193,596
1875	10,747,579	18,193,214
1876	9,756,683	18,707,328

American oyster fisheries.

The oyster fisheries of the United States are on a very large scale, and the coast line generally appears to abound with suitable localities for the production of these favorite mollusks. The oysters are all of a more or less elongated form, and of large size, sometimes growing to a length of 12 or 15 inches. They are obviously more suitable for cooking than for consumption in a natural state; and it is therefore not surprising that they are unable to compete with the favorite "native" in the English market. The trade in oysters in the principal cities of the United States in 1859 was estimated as follows:—[5]

	Bushels.
Virginia (State)	1,050,000
Baltimore	3,500,000
Philadelphia	2,500,000
New York	6,950,000
Fair Haven	2,000,000
Other cities	4,000,000
Total	20,000,000

---

[1] *Report on Newfoundland and Labrador Fisheries*, 1875, by Captain Erskine, R.N.

[2] Professor Baird says at page 19 of Part i. of his Report—"It is by no means to be inferred from our remarks as to the scarcity of fish that fewer are actually caught now than formerly at any time, the contrary, perhaps, being the case, since by means of the improved methods of capture, in the way of pounds and nets, an immense supply is taken out at certain seasons of the year, so as frequently to glut the markets. The scarcity is better shown by the great difficulty experienced by line fishermen in securing a proper supply throughout the year, on grounds where they were formerly able to catch all they needed for their own use and for sale."

[3] Baird, *Report* for 1871 and 1872, part i. p. 23.

[4] *Report of Fishery Commission*, Halifax, part ii. p. 63.

[5] Report by Lieutenant P. de Broca to the French Government, 1862, given in *Report* by Prof. Baird, pt. iii. p. 282 (1876).

Norwegian and Swedish fisheries.

Norwegian and Swedish Fisheries.—The important fishery of Norway is that for cod, and the special seat of it is at the Lofoden Islands. In 1876[1] the fishery was very successful, more than 22 millions of fish having been taken, a larger catch than in any previous year since 1860, excepting 1875. Of this number about 16 millions of fish were salted, and most of the remainder dried. The average price on the spot was £1, 6s. 8d. per 100. The Finmark cod fishery in the same year fell off very much, as will be seen by the following returns for the years 1872–6:—

1872	11,500,000 cod.
1873	16,000,000 "
1874	17,500,000 "
1875	19,750,000 "
1876	3,500,000 "

The catch of Norway mackerel in 1876 was 1,800,000 fish, and the estimated produce of the herring fishery in that year was 400,000 barrels; but the spring or winter herring disappeared about 1874, and the market has since been supplied with the large northern herring. A remarkable instance of the capricious movements of the herring has just been reported[2] by Mr. F. W. Duff, the British consul at Gothenburg, to the Foreign Office. He states that "great shoals of herrings of the large kind which disappeared from this coast in 1809 have now made their appearance again north of Gothenburg, on the coast in this country. The first appearance of the herring took place at Christmas (1877), when whales were seen following the shoals of herrings towards the coast." This is by no means the first time that herrings have returned to a particular locality after an interval of very many years.

French and Dutch fisheries.

French and Dutch Fisheries.—The French fisheries on the coast of the Channel are of much the same kind as those on the English side—trawling, drifting, and line-fishing. Trawling is carried on to a considerable extent from Boulogne, Treport, Calais, and some other places where there is convenient access to railways; and recently two companies have been established for trawling with steamers along the sandy coast between Arcachon and the mouth of the Gironde. On the coast of Brittany the long-standing fishery for sardines, or, as they really are, young pilchards, is regularly worked. It is remarkable that this fishery is almost entirely dependent for its success on a good supply of cod-roes, in which a large trade with Norway and other places is carried on solely for this purpose, the separated ova of the cod being freely scattered among the sardine nets in order to attract the fish. French and Dutch vessels work regularly in the North Sea for herrings and cod, and the French fish in large numbers along the east coast of England in company with English boats during the herring season. They also take part in the Kinsale mackerel fishery. The French fisheries at Newfoundland have been already noticed; considerable attention is also given by the French to the cod fishery at Iceland. About 200 French vessels visited Iceland in 1877, and during the five years 1872–6 the average annual produce of about 120 vessels from Dunkirk alone was 5 million kilos. of fish, and of oil about 500,000 kilos.[3]

The French oyster fisheries have for many years received considerable attention, and at Arcachon especially great success appears to have attended the cultivation of the beds. Eighty-five per cent. of the oysters obtained from these fisheries are said to be the produce of four or five breeding grounds, Auray and Arcachon being the most prolific. The total produce of all the French oyster fisheries in 1875 reached the enormous number of 97,227,000 oysters.[4]

Echinus fishery.

Echinus Fishery.—On the French and Italian coasts of the Mediterranean the *echini* or sea-eggs, animals belonging to the echinoderm or star-fish tribe, are regularly collected for the market, and are in great request among the poorer classes of the population. They are eaten uncooked, the egg-shaped spiny shell being divided into two parts by a single cut with a knife, and the soft and slippery contents then readily extracted. The echini form part of the various marine productions well known at Naples as *frutti di mare*.

Tripang fisheries.

Tripang Fishery.—The tripang or *bêche de mer* belongs to the order *Holothuriadæ* or sea-cucumbers. Representatives of the group are found in British seas, but by no means so abundantly or of such general large size as in tropical waters. Several species go under the commercial name of "tripang;" they are collected among almost all the islands of the Indian Archipelago down to New Guinea and Australia, and also on the north coast of Ceylon. In shape the tripang resembles a cucumber, but with a circle of short branched tentacles at one end, and surrounding the mouth. The color is generally black, more or less variegated with red or orange, and although sluggish in its movements, the animal has great power of contracting and altering its form. Coral reefs are favorite haunts of the tripang, and it is found in both deep and shallow water. The only preparation it receives after being gutted consists in drying in the sun and smoking over a wood fire. Macassar is the centre of the tripang trade, but the whole produce of the fisheries goes to China, and the trade is entirely in the hands of native merchants.

(E. W. H. H.)

Law relating to Fisheries.

Fish in English law fall under the general principles of the law as to animals *feræ naturæ*. All mankind, says Blackstone, had by the grant of the Creator an original right to pursue them; and this natural right still continues unless so far as it is restrained by the civil law. Accordingly everybody has a right to take fish in the seas, in public rivers, or in private rivers belonging to himself. In private (*i. e.*, non-navigable) rivers the right of fishery belongs *prima facie* to the owners of the land on either side, in public or navigable rivers to the public at large. In both, however, an exclusive right of fishery may exist, by which the presumptive right is excluded; and this, in the case of public rivers, can only take place by grant of the crown. Since Magna Charta the crown can no longer make such grants—at least such seems to be the better interpretation of the words in the statute.

These various rights are more or less roughly distinguished in English law as follows. A *common* fishery is the right of fishing in the sea and public rivers open to all the public. A *several* fishery is the exclusive right of an individual, derived through or on account of ownership of the soil. A *free* fishery is an exclusive right of fishing in public water, derived from royal grant. A *common* of fishery is the right of fishing "in another man's water," like common of pasture, etc. These rights include fish of all descriptions, with this exception that the crown has an old prerogative right to the whale and sturgeon, which, "when thrown ashore or caught near the coast, are the property of the sovereign on account (as it is said in the books) of their superior excellence." A curious distinction is made between the whale and the sturgeon:—*De sturgione observetur quod rex illum habebit integrum; de balena vero sufficit si rex habeat caput et regina caudam.*

As to the mode in which fish may be caught there does not seem to be any restriction at common law. It is a question, however, whether a wear, "by which is meant a fixed structure on the bed of the river, the object of which is, either by means of an apparatus which then catches them or by impeding their progress, to prevent all or nearly all the fish from passing upwards,"[5] is not illegal at common law. In the case of a public river a structure of this sort would be objectionable on the ground of its impeding the navigation, and in a case relating to the River Severn the judges held that the crown could not derogate from the public right of navigation by any grant to erect wears in a public river. The legal writer from whom we have quoted above, while stating that no case had arisen directly on the point in England, Scotland, or Ireland, is of opinion that "both wears and fixed nets, and all other apparatus which prevent fish passing to or fro are illegal at common law and form a good ground of action," even although they may not obstruct navigation. "Though one riparian owner may, by fishing by net or rod at all hours and by means of servants and assistants, almost use up the fish as effectually as by keeping fixed nets, this kind of user could not properly be a cause of action, just as one owner who has a large number of cattle could not be liable to an action at the suit of another who has no cattle, and so makes no use of the water. But it is otherwise where a total obstruction occurs. Hence, even independently of any statute, any fixed apparatus in a river or stream which prevents the fish going up to the other riparian owners is a good cause of action at common law, as it deprives him of one of the natural riparian rights."

A considerable number of statutes have been passed on the subject of fisheries, the most important of which are those relating to salmon. See Salmon.

[4] See a Report by Major Hayes to the Lord-Lieutenant of Ireland, 1878, which contains an immense amount of valuable information.

[5] *Fishery Laws of the United Kingdom*, by James Paterson, London 1863.

A short Act was passed in 1876 enabling boards of conservators to fix a close term for trout, commencing not earlier than 2d September, nor later than 2d November, and extending over 123 days. A bill for the protection of freshwater fish has passed through Parliament during the present session (1878). Sections 8 and 9 of the Salmon Fishery Act, 1861 (which relate to fishing with light spears and other prohibited instruments, and to using roe as a bait), shall, as amended by the subsequent Salmon Fishery Acts, apply to *trout* and *char* in all waters within the limits of the Act, which are the same as the limits of the Salmon Act. For all other freshwater fish, not migrating to or from the open sea, a close season is established from 1st March to 31st May, both inclusive. Fishing for or dealing in freshwater fish during this close season is subjected to a penalty not exceeding 40s. for the first or £5 for the second offence, recoverable on summary conviction before two justices. The Fisheries (Dynamite) Act is extended to private waters.

The Act 40 and 41 Vict. c. 62 is an Act to amend the law relating to the fisheries of oysters, crabs, and lobsters, and other sea fisheries. The sale of *oysters* is prohibited, in the case of "deep sea oysters," between 15th June and 4th August; in other cases between 14th May and 14th August. Oysters taken in foreign waters, or preserved in tins, or intended for the purpose of oyster cultivation are not within this section. The Board of Trade has power to temporarily prohibit or restrict dredging for oysters on certain banks. *Crabs* measuring less than 4½ inches across the back, or carrying spawn attached to the tail, etc., or having recently cast the shell may not be sold, except for bait. *Lobsters* measuring less than 8 inches "from the tip of the back to the end of the tail, when spread as far as possible flat," may not be sold. *Oysters* are also specially dealt with by the "Sea Fisheries Act, 1868," which is an Act to carry into effect a convention between England and France concerning the fisheries in the seas adjoining the British Islands and France, and to amend the laws relating to British sea fisheries.

International Law.—As between different nations, fishing in the high seas is common to all, while fishing in the territorial waters of any particular state (*i. e.*, within three miles of the coast) is limited to the subjects of that state. Between France and England the rights of fishing in the seas adjacent to both countries are regulated by the convention and Act of Parliament cited above. Between England and the United States questions of great importance have arisen as to their respective rights of fishing in North American waters. Mutual concessions were made by treaties in 1818, 1854, and 1871. The last was the Treaty of Washington, by which "the inhabitants of the United States are to have in addition to their rights under the treaty of 1818, in common with British subjects, for ten years from the date of the treaty and until the end of two years after notice has been given by either party, the right to take fish of every kind except shell-fish on the sea coasts and shores, and in the bays, harbors, and creeks of the provinces of Quebec, Nova Scotia, and New Brunswick, and the colony of Prince Edward's Island, and of the several islands thereto adjacent, without being restricted to any distance from the shore, with permission to land upon the said coasts and shores and islands, and also upon the Magdalen Islands for the purpose of drying their nets and curing their fish." Salmon and shad fisheries and all other fisheries in the rivers and mouths of rivers are reserved for British subjects. Exactly similar rights are granted to British subjects on the eastern sea coasts and shores of the United States north of the 39th parallel of north latitude. But inasmuch as the English Government insisted that the privileges granted to the United States were of greater value than those conceded to England, it was agreed that commissioners should be appointed to determine the amount of any compensation which ought to be paid to the English Government in consideration of such excess. The commissioners have recently made an award finding the sum of £1,000,000 to be due from the United States to England. Certain places designated in the abrogated treaty of 1854 are to be excepted from the operation of the treaty as "places reserved from the common right of fishing." (E. R.)

FISHES. See ICHTHYOLOGY and PISCICULTURE.

FISHING-FROG, also Frog-fish or Sea-devil (*Lophius piscatorius*), a fish well known off the coasts of Great Britain and Europe generally, the grotesque shape of its body and its singular habits having attracted the attention of naturalists of all ages. Its head is of enormous size, broad, flat, and depressed, the remainder of the body appearing merely like an appendage. The wide mouth extends all round the anterior circumference of the head; and both jaws are armed with bands of long pointed teeth, which are inclined inwards, and can be depressed so as to offer no impediment to an object gliding towards the stomach, but to prevent its escape from the mouth. The pectoral and ventral fins are so articulated as to perform the functions of feet, the fish being enabled to move, or rather to walk, on the bottom of the sea, where it generally hides itself in the sand or amongst sea-weed. All round its head and also along the body the skin bears fringed appendages resembling short fronds of sea-weed, a structure which, combined with the extraordinary faculty of assimilating the color of the body to its surroundings, assists this fish greatly in concealing itself in places which it selects on account of the abundance of prey. To render the organization of this creature perfect in relation to its wants, it is provided with three long filaments inserted along the middle of the head, which are, in fact, the detached and modified three first spines of the anterior dorsal fin. The filament most important in the economy of the fishing-frog is the first, which is the longest, terminates in a lappet, and is movable in every direction. There is no doubt that the fishing-frog, like many other fish provided with similar appendages, plays with this filament as with a bait, attracting fishes, which when sufficiently near, are engulfed by the simple act of the fishing-frog opening its gape. Its stomach is distensible in an extraordinary degree, and not rarely fishes have been taken out quite as large and heavy as their destroyer. It grows to a length of more than 5 feet; specimens of 3 feet are common. Young individuals are somewhat dissimilar in shape to old ones, and are provided with more numerous and longer appendages and filaments. The British species is found all round the coasts of Europe and western North America, but becomes scarce beyond 60° N. lat.; it occurs also on the coasts of the Cape of Good Hope. A second species (*Lophius budegassa*) inhabits the Mediterranean, and a third (*L. setigerus*) the coasts of China and Japan.

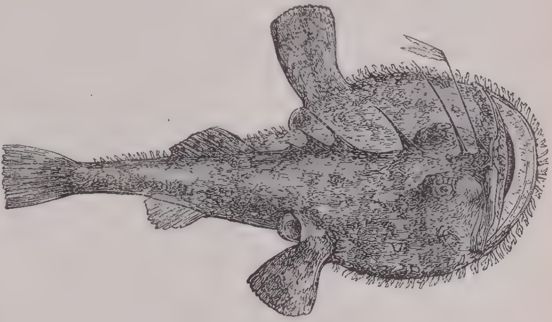

FIG. 1.—The Fishing-Frog (*Lophius piscatorius*).

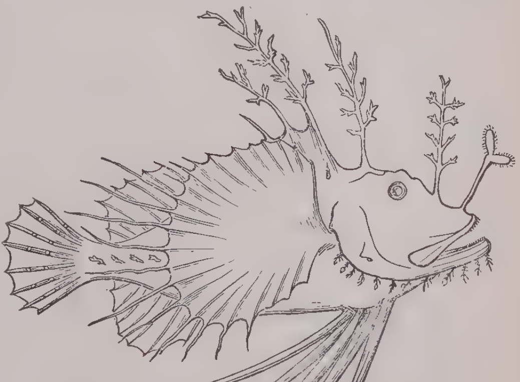

FIG. 2.—A young Fishing-Frog.

FISTULA, a term in surgery used to designate an abnormal communication leading either (1) from the surface of the body to a normal cavity or canal, or (2) from one normal cavity or canal to another. These communications are the result of disease or injury. They receive different names according to their situation:—*lachrymal fistula*, in connection with the lachrymal apparatus; *salivary fistula*, in connection with the salivary duct on the cheek; *anal fistula*, in connection with the anus; *urethral fistula* in connection with the urethra,—are all examples of the variety of the first kind of fistula; while *recto-vesical fistula*, a communication between the rectum and bladder, and *vesico-vaginal fistula*, a communication between the bladder and vagina, are examples of the second. The abnormal canal may be straight or tortuous, of considerable diameter or of narrow calibre. Fistulæ are formed in various ways:—(1) by an obstruction of the normal channel the result of disease or injury, which prevents, for example, the tears, saliva, or urine, as the case may be, from escaping; their retention gives rise to inflammation and ulceration, and the result is that they make a way of exit behind the obstruction; (2) by the formation of an abscess near, for example, the anus, which bursts into the gut and through the skin; the cavity does not close, and a *fistula in ano* is the result; (3) by destruction, by injury or ulceration, of the septum between one cavity and another, as in *recto-vesical fistula*, or between a cavity and a canal, as in *vesico-vaginal fistula*. The fistulous channel will remain patent as long as the contents of the cavity or canal with which it is connected pass along it in whole or in part. There is always a natural tendency to contraction. The treatment is founded on these principles:—remove the obstruction, encourage the flow along the natural channel; for example, open up the nasal duct, allow the tears to reach the nasal cavity, and the *lachrymal fistula* will close; so also in the *salivary* and *urethral* varieties. Sometimes it may be necessary to lay the channel freely open, and allow it to close from its deeper parts to the surface as in *anal fistula;* in other cases it may be necessary to pare the edges of the abnormal opening and stitch them together, hoping for union of the edges.

FITCH, John (1743–1798), one of the first inventors in connection with steam navigation, was born at Windsor, Connecticut, January 21, 1743. He was the son of a farmer, and received the usual common school education. At the age of seventeen he went to sea, but he discontinued his sailor life after a few voyages, and became successively a clock maker, a brassfounder, and a silversmith. During the rebellion he followed the trade of sutler to the American troops, and amassed in that way a considerable sum of money, with which he bought land in Virginia. He was appointed deputy-surveyor for Kentucky in 1780, and when returning to Philadelphia in the following year he was captured by the Indians, but shortly afterwards regained his liberty. About this time he began an exploration of the north-western regions, with the view of preparing a map of the district; and while sailing on the great western rivers, the idea occurred to him that they might be navigated by steam. He endeavored by the sale of his map to find money for the carrying out of his projects, but was unsuccessful. He next applied for assistance to the legislatures of different States, but though each reported in favorable terms of his invention, none of them would agree to grant him any pecuniary assistance. He was successful, however, in 1786, in forming a company for the prosecution of his enterprise, and shortly afterwards a steam-packet of his invention was launched on the Delaware. His claim to be the inventor of steam-navigation was disputed by James Rumsey of Virgia, but Fitch obtained exclusive rights in steam-navigation in New Jersey, Pennsylvania, and Delaware, while a similar privilege was granted to Rumsey in Virginia, Maryland, and New York. A steam-boat built by Fitch conveyed passengers for hire on the Delaware in the summer of 1790, but the undertaking was a losing one, and led to the dissolution of the company. In 1793 he endeavored to introduce his invention into France, but met with no success. On his return to America he found his property overrun by squatters, and reaping from his invention nothing but disappointment and poverty, he committed suicide in 1798. He left behind him a record of his adventures and misfortunes, "inscribed to his children and future posterity;" and from this a biography was compiled by Thompson Westcott (Philadelphia, 1857).

FITCH, Ralph, a London merchant and one of the earliest English travellers in India, lived in the latter half of the 16th century. As he was engaged in a traffic in Eastern products it occurred to him that he might pursue a more profitable trade were he to visit the countries from which they came. Accordingly, along with four other merchants, he re-embarked in January, 1583, in a ship called the "Tygre," and set sail for Tripoli in Syria. From Tripoli they journeyed to Aleppo and through Mesopotamia to Baghdad, from whence they sailed down the Tigris to Bussorah. From Bussorah they sailed in small boats down the Persian Gulf to the island of Ormus. Here from the jealousy of the other European merchants at their success, they were apprehended by the governor of the castle as spies and sent to the Portuguese viceroy at Goa. They afterwards received their liberty on paying a fine, but fearing a second imprisonment they escaped secretly from Goa, and journeyed through the interior of India. Fitch ultimately left his companions, and after reaching Bengal he sailed in 1589 for Cochin, touching on his way at Ceylon. After sojourning at Cochin eight months he re-embarked for Goa, and thence retraced his footsteps to Tripoli, finally reaching London on the 29th April, 1591. *The voyage of Mr. Ralph Fitch, Merchant of London, to Ormus and so to Goa, in the East India; to Cambaia, Ganges, Bengala; to Bacola and Chonderi; to Pegu, to Jamahay in the kingdom of Siam, and back to Pegu, and from thence to Malacca, Zeilan, Cochin, and all the Coast of the East Indies*, is included in Pinkerton's *Collection of Travels*.

FITCHBURG, a city of the United States, one of the capitals of Worcester county, Massachusetts, is situated on a branch of the Nashua river, 40 miles W.N.W. of Boston. It includes the villages of Crockerville, Rockville, South Fitchburg, Traskville, and West Fitchburg. It is the terminus of four railways—to Boston, Worcester, Brattleboro', and Keene and Bellows Falls. The principal buildings are the masonic hall, the city hall, the jail, the court-house, and the high school. It has woollen, cotton, and paper mills, machine shops, chair manufactories, iron foundries, and brass foundries. Fitchburg was originally included under Lunenburg. It was incorporated as a separate town in 1764, and became a city in 1872. The population in 1860 was 7805, and in 1870 it amounted to 11,260, 2517 being foreigners.

FITZGERALD, Lord Edward (1763–1798), one of the leaders of the Society of United Irishmen, was a younger son of the first duke of Leinster, and was born at Carton Castle, near Dublin, October 15, 1763. At ten years of age he lost his father, and, his mother marrying again, the family soon after settled in France. Lord Edward was carefully educated by his stepfather, Mr. Ogilvie, chiefly with a view to the profession of a soldier. Returning to England in 1779 he entered the English army, and in 1781 he sailed with his regiment for America, where he soon obtained the appointment of aide-de-camp on the staff of Lord Rawdon. He served in the war with no little reputation for personal courage, readiness of resource, and humane feeling. He was severely wounded at the battle of Eutaw Springs. After the surrender of York Town he joined the staff of General O'Harra at St. Lucia, and the same year (1783) returned to Ireland. He was soon returned as member for Athy to the Irish parliament; but the high hopes which he had cherished of serving his country faded away at the spectacle of political corruption and suppression of all genuine representation by the penal laws against Roman Catholics. In 1787 he set out for a visit to the south of Europe, went afterwards to America, and in 1790 returned to England, and soon resumed his seat in the Irish parliament. The French Revolution had broken out, and Lord Edward was one of those ardent spirits that welcomed with enthusiasm the promise of its first days. In 1792 he was attracted to Paris, and made the acquaintance of the most famous leaders of the Revolution. Having publicly renounced his title of nobility and avowed his sympathy with the republicans, he was dismissed, with other officers, from the English army. It was during this visit to Paris that he was introduced to the lady then known as "Pamela," the daughter of Madame de Genlis, by the duke of Orleans ("Égalité"). In December, 1792, they were married at Tournay, and returned to Ireland in January, 1793. After a period of singular happiness spent in a country home, his sympathies with the struggles of his countrymen led him out to the troubled arena of politics. He joined in 1796 the society of United Irishmen, was sent to France to negotiate a treaty with the Directory for a French invasion of Ireland, and urged on with the utmost zeal the preparations for an Irish insurrection. But the scheme was betrayed, several of the leaders were arrested, and Fitzgerald concealed himself in a house at Dublin, still continuing to direct the movement. A price was set on his head, the place of his retreat was discovered, and after a severe struggle he was captured by police officers (May 19, 1798), and committed to prison. There he died on the 4th of June, of the wounds which he had received; a bill of attainder was immediately passed against him, and his estates were confiscated; but the attainder was at a later time reversed. His widow married Mr. Pitcairn, American consul at Hamburg; but the union was an unhappy one, and ended in a separation by mutual consent. Lady Fitzgerald henceforward lived in retirement at Montauban till 1830, when she removed to Paris, Louis Philippe, the associate of her childhood, having become king of the French. He, however, refused to see her, and she died poor in 1831. An interesting narrative of *The Life and Death of Lord Edward Fitzgerald*, by Thomas Moore, was published in 1831, in 2 vols. 8vo. A cheap reprint in 1 vol. was issued in 1875.

FITZGERALD, Lord Thomas (d. 1536), was vice-deputy of Ireland for his father, Gerald, ninth earl of Kildare, in the reign of Henry VIII. He appears to have accompanied his father to London early in 1534, on occasion of the third summons of the earl to answer grave charges of maladministration as lord deputy. But after the earl's committal to the Tower he was sent back to Ireland to take the place of vice-deputy in his father's absence, with secret instructions to raise a rebellion against the English Government. He was at this time hardly of age, and his amiable manners and accomplishments had procured for him the appellation of "Silken Thomas." He was, however, of a high spirit and fiery temper, and fiercely resented the English rule. As soon as he arrived in Ireland, he cleared the way by formally surrendering his office and the sword of state, and then openly proclaimed a rebellion. He obtained possession of Dublin city before the end of July, and formed the siege of the castle, into which the English governor had withdrawn. Archbishop Allen, the primate who had been appointed by Henry VIII. to keep watch over Kildare and to report his proceedings, sought safety in flight and sailed for England. But the ship was run aground, and the archbishop was seized by the young Lord Thomas and massacred in his presence with his English chaplains and attendants. This murder was reported by a special messenger from Fitzgerald to the pope and the emperor, the former being asked for absolution if necessary, and the latter for assistance. Sentence of excommunication was pronounced on Fitzgerald for this murder of the archbishop. In August, Fitzgerald was forced to relinquish the siege of Dublin Castle, and hasten to defend or recover his own domains which the earl of Ormond had invaded. He tried in vain to seduce Ormond from his allegiance, but obtained a truce, of which he took treacherous advantage to attack him. He then again besieged Dublin, which had closed its gates against him. On October 14, in consequence of Ormond's renewed invasion of Kildare, he was compelled to raise the siege. Three days later the English army landed at Dublin, and was enthusiastically welcomed. Fitzgerald withdrew into the country; but, taking advantage of the inactivity of Skeffington, the new deputy, he approached Dublin again and burnt two villages near the city (November). The old earl had been attainted, and he died in the Tower soon after hearing of his son's rebellion and excommunication. The deathblow to the rebellion was at length given by Skeffington, who in March, 1535, stormed the castle of Maynooth, the chief stronghold of the "Geraldines." Lord Thomas, who had now succeeded his father, but did not assume the title, retreated into Thomond, intending to sail for Spain and plead with the emperor. This scheme he relinquished, and after leading a wandering life for some months, with a price set upon his head, he surrendered without definite conditions to Lord Leonard Grey (August), and was at once conducted by him to England. He was committed to the Tower with his five uncles; and the six Geraldines were hung at Tyburn as traitors (February 3, 1536). An act of attainder was passed against the earl of Kildare, Lord Thomas, and others, in 1537; but the family estates were restored by Edward VI., and the attainder was repealed by Queen Elizabeth. Moore has pointed out, in his *Life and Death of Lord Edward Fitzgerald*, some remarkable points of resemblance between his story and that of his ancestor, Lord Thomas.

FITZHERBERT, Sir Anthony, an eminent English lawyer, was born at Norbury. After studying at Oxford, he was called to the English bar, and in 1523 became justice of the court of common pleas, the duties of which office he continued to discharge till within a short time of his death in 1538. As a judge he left behind him a high reputation for fairness and integrity, and his legal learning is sufficiently attested by his published works.

He is the author of *Le graunde abridgement*, a digest of important legal cases written in Old French, first printed in 1524; *The Office and Authority of Justices of the Peace*, first printed in 1538, last ed. 1794; the *New Natura Brevium*, 1534, last ed. 1794, with a commentary ascribed to Sir Matthew Hale; and the *Book of Husbandry*, 1523, the first published work on agriculture in the English language.

FITZROY, Robert (1805–1865), a vice-admiral in the English navy, distinguished as a hydrographer and meteorologist, was born at Ampton Hall, Suffolk, July 5, 1805, being a grandson, on the father's side, of the third duke of Grafton, and on the mother's, of the first marquis of Londonderry. He entered the navy from the Royal Naval College, then a school for cadets, on the 19th October, 1819, and on the 7th September, 1824, was promoted to the rank of lieutenant. After serving in the "Thetis" frigate in the Mediterranean and on the coast of South America, under the command of Sir John Phillimore and Captain Bingham, he was in August, 1828, appointed to the "Ganges," as flag-lieutenant to Rear-Admiral Sir Robert Otway, the commander-in-chief on the South American station; and on the melancholy death of Commander Stokes of the "Beagle," 13th November, 1828, was promoted to the vacant command. The "Beagle," a small brig of about 240 tons, was then, and had been for the two previous years, employed on the survey of the coasts of Patagonia and Tierra del Fuego, under the orders of Commander King in the "Adventure," and, together with the "Adventure," returned to England in the autumn of 1830. Fitzroy had brought home with him four Fuegians, one of whom died of small-pox a few weeks after arriving in England; to the others he endeavored, with but slight success, to impart a rudimentary knowledge of religion and of some useful handicrafts; and, as he had pledged himself to restore them to their native country, he was making preparations in the summer of the following year to carry them back in a merchant ship bound to Valparaiso, when he received his reappointment to the "Beagle," to continue the survey of the same wild coasts. The "Beagle" sailed from Plymouth on the 27th December, 1831, carrying as a supernumerary Mr. Charles Darwin, to whose experience, then gained, the study of natural history has been so deeply indebted. After an absence of nearly five years, and having, in addition to the survey of the Straits of Magellan and a great part of the coast of South America, run a chronometric line round the world, thus fixing the longitude of many secondary meridians with sufficient exactness for all the purposes of ordinary navigation, the "Beagle" anchored at Falmouth on the 2d October, 1836. In 1834 Fitzroy had been advanced to the rank of captain, and was now for the next few years principally employed in reducing and discussing his numerous observations. In 1837 he was awarded the gold medal of the Royal Geographical Society; and in 1839 he published, in two thick 8vo volumes, the narrative of the voyage of the "Adventure" and "Beagle," 1826–30, and of the "Beagle," 1831–36, with a third volume by Mr. Darwin—a book familiarly known as a record of scientific travel. Of Fitzroy's work as a surveyor it is superfluous to speak. Though carried on under circumstances of great difficulty, with scanty means, and with an outfit that was semi-officially denounced as "shabby," the results have long been before the world stamped with the approval of the nautical profession, and more especially of Sir Francis Beaufort, the Hydrographer to the Admiralty, who, in a report to the House of Commons, 10th February, 1848, wrote that "from the equator to Cape Horn, and from thence round to the river Plata on the eastern side of America, all that is *immediately*[1] wanted has been already achieved by the splendid survey of Captain Robert Fitzroy."

In 1841 Fitzroy unsuccessfully contested the borough of Ipswich, and in the following year was returned to parliament as member for Durham. About the same time he accepted the post of conservator of the Mersey, and in his double capacity obtained leave to bring in a bill for improving the condition and efficiency of officers in the mercantile marine. This was not proceeded with at the time, but gave rise to the "voluntary certificate" instituted by the Board of Trade in 1845, and furnished some important clauses to the Mercantile Marine Act of 1850.

---

[1] This was written 30 years ago, before steam ships nearly 400 feet long made the Straits of Magellan a high road to the Pacific. The survey that was sufficient then is very far from sufficient now.

Early in 1843 Fitzroy was appointed governor and commander-in-chief of New Zealand, then recently established as a colony. He arrived in his government in December, whilst the excitement about the Wairau massacre was still fresh, and the questions relating to the purchase of land from the natives were in a very unsatisfactory state. The early settlers were greedy and unscrupulous; Fitzroy, on the other hand, had made no secret of his partiality for the aborigines. Between such discordant elements agreement was impossible: the settlers insulted the governor; the governor did not conciliate the settlers, who denounced his policy as adverse to their interests, as unjust and illegal; colonial feeling against him ran very high; petition after petition for his recall was sent home, and the Government was compelled to yield to the pressure brought to bear on it. Fitzroy was relieved by Sir George Grey in November, 1845.

In September, 1848, he was appointed acting superintendent of the dockyard at Woolwich, and in the following March to the command of the "Arrogant," one of the early screw frigates which had been fitted out under his supervision, and with which it was desired to carry out a series of experiments and trials. When these were finished he applied to be superseded, on account at once of his health and of his private affairs. In February, 1850, he was accordingly placed on half-pay; nor did he ever serve again, although advanced in due course by seniority to the ranks of rear and vice-admiral on the retired list (1857, 1863). In 1851 he was elected a fellow of the Royal Society, and in 1854 after serving for a few months as private secretary to his uncle, Lord Hardinge, the commander-in-chief of the army, he was appointed to the meteorological department of the Board of Trade, with, in the first instance, the peculiar title of "Meteorological Statist."

From the date of his joining the "Beagle" in 1828 he had paid very great attention to the different phenomena foreboding or accompanying change of weather, and his narratives of the voyages of the "Adventure" and "Beagle" are full of interesting and valuable details concerning these. Accordingly, when in 1854 Lord Wrottesley, the president of the Royal Society, was asked by the Board of Trade to recommend a chief for its newly forming meteorological department, he, almost without hesitation, nominated Fitzroy, whose name and career became from that time identified with the progress of practical meteorology. His *Weather Book*, published in 1863, embodies in broad outline his views, far in advance of those then generally held; and though, in the rapid march of modern science, this book must be considered as now in some measure obsolete, it is still worthy of careful attention and exact study, not only from the professed meteorologist, but from any one who wishes to have an intelligent appreciation of that question of everyday interest, the weather. His storm warnings, in their origin, indeed, liable to a charge of empiricism, were gradually developed on a more scientific basis, and gave a high percentage of correct results. They were continued for eighteen months after his death by the assistants he had trained, and though stopped when the department was transferred to the management of a committee of the Royal Society, they were resumed a few months afterwards. But though it is perhaps by these storm warnings that Fitzroy's name has been most generally known, seafaring men owe him a deeper debt of gratitude, not only for his labors in reducing to a more practical form the somewhat complicated wind charts of Captain Maury, but also for his great exertions in connection with the life-boat association. Into this work, in its many ramifications, he threw himself with the energy of an excitable temperament, already, it may be feared, strained by his long and anxious service in the Straits of Magellan. His last years were fully and to an excessive degree occupied by it; his health, both bodily and mental, threatened to give way; but he refused to take the rest that was prescribed. In a fit of mental aberration he put an end to his existence on the 30th April, 1865.

Besides his works already named mention may be made of *Remarks on New Zealand* (1846); *Sailing Directions for South America* (1848); his official reports to the Board of Trade (1857–65); and occasional papers in the journal of the Royal Geographical Society and of the Royal United Service Institution. (J. K. L.)

FITZSTEPHEN, William, an English historian, was a native of London, and died in 1191. Becoming a monk of Canterbury, he had very confidential relations with Thomas à Becket. Shortly after the death of Thomas he wrote his life in Latin, a work which bears internal evidence of greater impartiality and truthfulness than most of the archbishop's biographies, and is besides of interest as containing a long description of the city of London. There is a manuscript copy of the work in the British Museum.

A translation of the description of London was inserted by Stowe in his *Survey of London*, and in 1772 Dr. Pegge published a new and more correct edition, in Latin and English, accompanied with notes and an essay on the author. A corrected version, with a translation, was also inserted in the edition of Stowe's *Survey* published in 1843.

FIUME (Slav. Rieka, German St. Veit-am-Flaum), a royal free town and port of Hungary situated at the northern extremity of the Gulf of Quarnero, on the Recina (Fiumara), 46 miles by road S.E. of Trieste, 45° 19′ 19″ N. lat., 14° 26′ 43″ E. long. It consists of an old and a new town, the former standing on a hill, the latter extending along the shore. The population in 1869 amounted to 14,039 for the town, and 4770 for the territory of Fiume: of these the greatest number were Roman Catholics. Among the many important buildings are the old chapter or cathedral church of the Assumption of the Virgin, and the church of St. Veit, built in imitation of Sta. Maria della Salute at Venice, the theatre, capable of holding 1600 persons, the palace of Gorup, the barracks, and the elegant marine academy founded in 1856. In the old town is an ancient Roman triumphal arch, said to have been erected in honor of the emperor Claudius II. Fiume possesses several educational establishments, among which are a real-gymnasium, two municipal high schools, and a Croatian gymnasium. The consuls of several states reside in the town, which is the seat of a high court of justice for commerce and marine, and of a chamber of industry and commerce. Among the benevolent institutions are asylums for lunatics and decayed citizens, and an industrial home for boys. Notwithstanding the revival of trade at Trieste, commercial enterprise and industry have considerably increased at Fiume, and the town has now two railways, opened in 1873—one a branch of the southern railway from Vienna to Trieste, the other of the Hungarian state railway from Carlstadt. Fiume is the immediate outlet by sea for the produce of Hungary, with which country it is connected by the Louisen-strasse, opened in 1809. It has two harbors —Porto Canale Fiumara, suitable only for coasting-vessels and small craft, and Porto Nuovo, affording good accommodation for large ships. The latter port, commenced in 1847, is now (1878) being much enlarged and extended to meet the increasing requirements of trade, and when completed will occupy an area of 57½ acres, and afford quay accommodation for 100 large vessels. The chief exports are wheat, wine, tobacco, timber, rags, salt, rape-seed, hemp, and paper, of which last the annual exports amount to upwards of 30,000 cwt. Foremost among the industrial establishments are Whitehead's torpedo factory, Messrs. Smith & Meynie's paper-mill, the royal tobacco factory (furnishing yearly more than 200 million cigars and cigarettes, and employing above 3000 hands), a chemical factory where 1600 tons of sulphate of soda are annually made, and a large steam flour-mill. Besides these may be mentioned several shipbuilding yards, tanneries, and rope manufactories. The soil of the surrounding country is stony, but the climate is warm, and wine is extensively produced. The Gulf of Quarnero yields a plentiful supply of fish, and the tunny trade with Trieste and Venice is of considerable importance.

Fiume is supposed to occupy the site of the ancient Liburnian town *Tersatica*; later it received the name of Vitopolis, and eventually that of Fanum Sancti Viti ad Flumen, from which its present name is derived. It was destroyed by Charlemagne in 799, from which time it probably long remained under the dominion of the Franks. It was held in feudal tenure from the patriarch of Aquileia by the bishop of Pola, and afterwards, in 1139, by the counts of Duino, who retained it till the end of the fourteenth century. It next passed into the hands of the counts of Wallsee, by whom it was surrendered in 1471 to the emperor Frederick III., who incorporated it with the dominions of the house of Austria. From this date till 1776 Fiume was ruled by imperial governors. In 1723 it was declared a free port by Charles VI., in 1776 united to Croatia by the empress Maria Theresa, and in 1779 declared a *corpus separatum* of the Hungarian crown. In 1809 Fiume was occupied by the French; but it was retaken by the English in 1813, and restored to Austria in the following year. It was ceded to Hungary in 1822, but after the revolution of 1848–49 was annexed to the crown lands of Croatia, under the government of which it remained for the next twenty years. Since August, 1870, the town and territory of Fiume have been under the direct control of the Hungarian central Government.

See "Fiume and her New Port," by G. L. Faber, H.B.M. Vice-Consul at Fiume, in *Jour. of the Soc. of Arts*, Nov., 1877.

FIVES is a game which has existed in various forms from the earliest times. The name is derived from the essential feature of the pastime, consisting in striking a ball with the five digits of the human hand, the idea of there sometimes having been five players on each side requiring confirmation. Amongst the Greeks the *ἀπόῤῥαξις* was somewhat akin, since a ball was struck with the hand as many successive times as possible at each rebound from the ground. Of the method of playing the Roman *pila* we possess no details. Horace (*Sat.*, i. 5, 48) speaks of it thus:—

> Lusum it Mæcenas, dormitum ego Virgiliusque;
> Namque pila lippis inimicum et ludere crudis.

Judging from these lines the ball play of that day must have been both fatiguing and dangerous. In the *Close Roll*, 39 Edward III. (1365) mem. 23, *pila manualis* is mentioned as one of those pastimes which had caused the recent deterioration of archery, and some description of fives is no doubt referred to. During the 15th century palm play in England and *jeu de paume* in France were the chief analogous pastimes. In recent times our great public schools and universities have become the sole nurseries of fives. In the "open" court the only desiderata are a level piece of ground with a smooth wall in front against which the ball is struck. A "close" court has in addition two side-walls at right angles to the front one, and the whole may or may not be covered in. The invariable principle is to strike the ball, not later than at its first rebound from the ground, against the front wall and above a certain line as many consecutive times as possible. A single game comprises one player a side, a double one two. The minor rules vary at most schools and universities, and are generally handed down by tradition. About two inches is the usual diameter of the ball, the core being made of india-rubber, bound round with fine twine, and covered with white leather.

FIVES, a town in France, department of the Nord, now administratively connected with Lille. See LILLE.

FIX, THEODORE (1800–1846), a French journalist and political economist, was born at Soleure in Switzerland in 1800. His father was a French physician who had been expatriated by the edict of Nantes. Young Fix adopted at first the profession of a land surveyor, but, tiring of the monotony of this employment, he in 1830 became connected with the *Bulletin Universel des Sciences*, to which he contributed most of the geographical articles. In 1833 he founded the *Revue mensuelle d'Économie Politique*, which he continued till 1836. He also contributed to *Le Siècle*, *La Quotidienne*, *Le Journal des Économistes*, and *La Revue Nouvelle*. An article of his in the August number of the *Revue Nouvelle* for 1846, on the religious condition of Germany, attracted considerable attention. His principal work is *Observations sur les Classes Ouvrières*, 1846, in which he argues against all attempts to regulate artificially the rate of wages. His pamphlet on *L'Association des Douanes Allemandes* was in 1840 crowned by the Academy of Sciences, but has not been published. He died suddenly at Paris, 31st July, 1846.

FIXTURES, in law, may be defined as things which have been fixed or attached to land, or, as it is expressed in English law, things annexed to the freehold. All systems of law make a marked distinction between immovables and movables, between real and personal property, between land and all other things. In the case of fixtures the question arises under which set of rights they are to fall—under those of real or of personal property. The general rule of English law is that everything attached to the land goes with the land—*quidquid plantatur solo, solo cedit.* This, like many other rules of English law, is all in favor of the freeholder; and its injustice has been modified by a large number of exceptions formulated from time to time by the courts as occasion arose.

As to the kind of "fixing" necessary to change the legal character of the thing fixed, it would not be easy to lay down any precise rule. Things merely resting on the ground by the force of their own weight, removable easily and without damage to the soil, and intended not for the improvement of the inheritance but for temporary use, would not be regarded as fixtures. On the other hand, there is what is called constructive annexation, when the articles in question are not in any sense fixed at all, but pass with the freehold as if they were, *e.g.*, the keys of a house, heirlooms, etc.

Questions as to the property in fixtures may arise—(1) between landlord and tenant, (2) between heir and executor, (3) between executor and remainder-man or reversioner. These are the principal cases.

(1.) As a general rule, if the tenant has affixed anything to the freehold during his occupation, he cannot remove it without the permission of his landlord. But an exception was established in favor of *trade fixtures.* In a case before Lord Holt it was held that a soap-boiler might, *during his term*, remove the vats he had set up for trade purpose, and that not by virtue of any special custom, but "by the common law in favor of trade, and to encourage industry." Agriculture is not a trade within the meaning of this exception, and fixtures erected by a farmer for the purposes of agriculture may not be removed without the landlord's consent. On the other hand, nurserymen and gardeners, whose industry closely resembles agriculture, are allowed to remove trees, shrubs, etc., planted by them with a view to sale. It seems probable that the introduction of more elaborate mechanical processes in agriculture—particularly the use of steam-power—may have the effect of modifying the law as to agricultural fixtures. The statute 14 and 15 Vict. c. 25 enacts that, when a tenant-farmer has, with the written consent of his landlord, erected buildings, machinery, etc., for agricultural or trade purposes, the same shall be his property, and removable by him, after giving notice to the landlord, who may, however, elect to purchase them.

Again, *ornamental* fixtures, such as hangings and looking-glasses, tapestry, iron-backs to chimneys, wainscot fixed by screws, marble chimney-pieces, are held to belong to the tenant, and to be removable without the landlord's consent. Here again the extent of the privilege is a matter of some uncertainty. In one case it was held that the privilege did not extend to a conservatory erected on a brick foundation 15 inches deep, and connected with other buildings. Mr. Amos, in his book on fixtures, mentions four points which would be important in settling whether an ornamental fixture is removable or not:—(1) the mode in which it is united with the freehold; (2) its nature and construction, whether meant to be a temporary or permanent improvement; (3) whether it can be easily removed without injury to the freehold; (4) whether there is any local usage.

In all these cases the fixtures must be removed during the term. If the tenant gives up possession of the premises without removing the fixtures, it will be presumed, it appears, that he has made a gift of them to the landlord, and that presumption probably could not be rebutted by positive evidence of a contrary intention. His right to the fixtures is not, however, destroyed by the mere expiry of the term, if he still remains in possession; but if he has once left the premises, he cannot come back and claim his fixtures. In one case where the fixtures had actually been severed from the freehold after the end of the term, it was held that the tenant had no right to recover them.

(2.) As between heir and executor or administrator. The question of fixtures arises between these parties on the death of a person owning land. His real property goes to his heir; his personal property goes to his executor. In this case exceptions introduced in favor of the tenant are not allowed in favor of the executor, for, as it is said, the "heir is a favorite of the law." There is some conflict of authorities on this point, and cases might be cited on both sides of the question, whether the executor as against the heir has a right to ornamental or even to trade fixtures. Thus in one case a cider-mill let into the ground was held to belong to the executor; in another (a Scotch case before the House of Lords) colliery machinery was awarded to the heir, although portions of it might have been detached without any injury to the land. Blackstone lays down the rule that whatever is strongly affixed to the freehold (*quod ex ædibus non facile revellitur*) passes to the heir.

(3.) When a tenant for life of land dies the question of fixtures arises between his representatives and the persons next entitled to the estate (the remainder-man or reversioner) The remainder-man is not so great a favorite of the law as the heir, and the right to fixtures is construed more favorably for executors than in the preceding cases between heir and executor. Whatever is executor's fixtures against the heir would therefore be executor's fixtures against the remainder-man. And the result of the cases seems to be that, as against the remainder, the executor of the tenant for life would be certainly entitled to trade fixtures.

Similar questions may arise in other cases, *e.g.*, as between mortgagor and mortgagee. When land is conveyed the fixtures pass with it, unless a contrary intention is expressed in the conveyance. Again, in reference to bills of sale the question arises. Bills of sale are dispositions of personal property similar to mortgages, the possession remaining with the person selling them. To make them valid they must be registered. and so the question has arisen whether deeds conveying fixtures ought not to have been registered as bills of sale. Unless it was the intention of the parties to make the fixtures a distinct security, it seems a deed of mortgage embracing them does not require to be registered as a bill of sale.

FLACCUS, Caius Valerius, a Roman poet of the first century of the empire, of whose personal history little or nothing is known. He has been identified, but on wholly insufficient grounds, with the Flaccus, a poet friend of Martial, to whom the 77th epigram of the 1st book is addressed, and hence described as a native of Padua, and in needy circumstances. In the subscription of the Vatican MS. the names *Setinus Balbus* are appended, whence it is probable that he was born at Setia in Campania. The sole notice of him found in classical authors is a short sentence of Quintilian (*Inst.*, x. 1, 90), "Multum in Valerio Flacco nuper amisimus," whence we gather that he must have died before 90 A. D., though it does not follow, as is commonly stated, that he was cut off by an untimely death. If we turn for information to his only known work, the *Argonautica*, we learn from the dedication, which is addressed to Vespasian, that it was written during the siege or shortly after the fall of Jerusalem, 70 A. D. The *Argonautica* is an epic on the quest of the golden fleece. The poem is unfinished, the eighth book terminating abruptly with the request of Medea to accompany Jason on his homeward voyage. It is a free imitation and in parts a translation of the work of Apollonius of Rhodes, which had already been made familiar to the Romans by the popular version of Varro Atacinus. Various estimates have been formed of the genius of Flaccus, and some competent critics, such as Scaliger, Heinsius, and Weichart, have ranked him above his original. His diction is pure, his style correct, his versification smooth though monotonous, and he has some descriptive power, as is shown in the storm of the eighth book, and the picture of the dragon lulled to sleep by Medea's charms. On the other hand, he is wholly without originality, and his poetry reads as if made to order. It is free from glaring defects, but is rendered all but worthless by its monotony, artificiality, and elaborate dulness. He deserves, no less than Silius Italicus, to be called the ape of Virgil. One instance will suffice to show how he has vulgarized the great poet. The desertion of Hypsipyle by Jason in the second book is closely modelled on the desertion of Dido by Æneas, but instead of "Si quis mihi parvulus aula luderet Æneas," we have "Per hunc utero quem linquis Iasona nostro;" instead of "Quem sese ore gerens," etc., "Tales humeros ea terga relinquit." The corruptions of the text, and the obscurity of the mythological and geographical allusions, have attracted commentators and critics, but few except professed scholars will care to read a second-rate copy of a second-rate poet.

Bibliography.—The *Argonautica* was unknown till the first three books and half of the fourth were discovered by Poggio at St. Gall when attending the council of Constance. The *editio princeps* was published at Bologna, 1474, from the Vatican MS. 3277. Among other editions we may mention Burman's *Variorum*, Leyden, 1724; J. A. Wagner's, Göttingen, 1805; G. Thilo's, Halle, 1863 (the first careful collation of the Vatican MS.): C. Schenkl's, Berlin, 1871; and the 8th book annotated by A. Weichert, Meissen, 1817. There are translations into French prose by J.-J. A. Caussin de Perceval in the *Bibliothèque Latine-Française;* into French verse by Dureau de la Malle, Paris, 1811; and into Spanish verse by D. J. de Leon Bendicho y Quilty, Madrid, 1868; into Italian by Pindemonte, Verona, 1776; into German by Wunderlich, Erfurt, 1805. Warton speaks doubtfully of an English version: "We seem to have had a version of Valerius Flaccus in 1565; for, in that year. I know not if in verse or prose, was entered to Purfoote 'The story of Jason, how he gotte the golden flece, and how he did begyle Media, out of Latin into Englische, by Nycholas Whyte.'" The book is not recorded by Watt, nor is it in the British Museum.

FLACIUS (in German Vlacich), Matthias, surnamed Illyricus (1520–1575), a celebrated German theologian of the time of the Reformation, was born at Albona in Illyria in 1520. Having lost his father in early childhood, he owed his education almost wholly to his own unaided perseverance. At the age of seventeen he had resolved to enter a convent in order to devote his life to sacred learning; but on the advice of one of his relations, who had imbibed Reformation principles, he abandoned his intention, and pursued his studies successively at Basel, Tübingen, and Wittenberg. At Wittenberg he fell for a time into religious despondency, and sought the advice of Martin Luther, who was successful not only in removing his doubts, but in inspiring him with much of his own R formation zeal. In 1544 he became professor of Old Testament literature at Wittenberg, and soon began to take an active and prominent part in the theological discussions of the time. He strenuously opposed the Augsburg Interim and also the compromise of Melanchthon, known as the Leipsic Interim, and was compelled on that account to resign his professorship. From Wittenberg he proceeded to Magdeburg, and in 1557 he was appointed professor of theology at Jena, but soon became involved in a controversy with his colleague Strigel on the power of the human will in conversion. Being a strong upholder of the doctrine of man's natural inability, he was induced by controversial straits to fall unwittingly into the Manichæan heresy of affirming that original sin was not an accident in human nature, but now belonged to its substance; and as he would not submit to ecclesiastical censure, he was compelled in 1562 to resign his office. After staying for five years in retirement at Ratisbon, he accepted the charge of a congregation in Antwerp, but was soon compelled by religious persecution to leave that city for Strasburg. Here his views regarding original sin again exposed him to ecclesiastical censure, and he went to Frankfort-on-the-Maine, in the hospital of which city he died in 1575, having spent the latter years of his life in great poverty. Though the keen and uncompromising controversial spirit of Flacius ultimately deprived him of the sympathy of almost all his friends, he is better known to posterity for his labors in hermeneutics and church history than as a controversialist. He may almost be called the founder of the science of hermeneutics, and in the department of church history he rendered important service by tracing to their source the legends and superstitious traditions by which, in the annals of the church, truth had in a great measure been either concealed or superseded. Among his numerous works may be mentioned his *Clavis Scripturæ Sacræ*, and the *Catalogus Testium Veritatis*, which he contributed to the *Magdeburg Centuries.*

FLACOURT, Étienne de (1607–1660), a French governor of Madagascar, was born at Orleans in 1607. When he was named governor of Madagascar by the East India Company in 1648, the French troops had mutinied against the former governor, and a large number of them had also been massacred by the natives. Flacourt soon restored order among the soldiers, but in his dealings with the natives he was less successful, and their intrigues and attacks kept him in continual harassment during all his term of office. As he was in uncertainty regarding the affairs of the company, he returned in 1655 to France. Not long after he was appointed director general of the company; but, having again returned to Madagascar, he

was drowned on his voyage home, 10th June, 1660. Several unknown districts of Madagascar and some small islands in its neighborhood were explored by the orders of Flacourt, and he also in 1649 took possession of the island of Mascareigne, which he named Bourbon. He is the author of a *Histoire de la grande isle Madagascar* (1st edition 1658, 2d edition 1661), which is divided into two parts,—the first containing an account of the island, its inhabitants, and its natural history, and the second detailing the history of the events connected with its occupation by the French. Of this work the only portion of much value is the natural history section, which gives evidence of a considerable amount of minute and careful observation. He published also in 1658 a dictionary of the language of the island, which, however, is very incomplete and full of mistakes.

Plate I.

FLAG. It is probable that almost as soon as men began to collect together for common purposes some kind of conspicuous object was used, as the symbol of the common sentiment, as the rallying point of the common force. In military expeditions where any degree of organization and discipline prevailed, objects of such a kind would be necessary to mark out the lines and stations of encampment, and to keep in order the different bands when marching or in battle. And, in addition to all this, it cannot be doubted that flags or their equivalents have often served, by reminding men of past resolves, past deeds, past heroes, to rally to enthusiasm those sentiments of *esprit de corps*, of family pride and honor, of personal devotion, patriotism, or religion, upon which, as well as upon good leadership, discipline, and numerical force, success in warfare depends.

Among the remains of that people which has left the earliest traces of civilization, the records of the forms of objects used as ensigns are frequently to be found. From their carvings and paintings, supplemented by ancient writers, it appears that the several companies of the Egyptian army had their own particular standards. These were formed of such objects as there is reason to believe were associated in the minds of the men with feelings of awe and devotion. Sacred animals, boats, emblems, or figures, a tablet bearing a king's name, fan and feather-shaped symbols, were raised on the end of a staff as standards, and the office of bearing them was looked upon as one of peculiar privilege and honor (fig. 1). Somewhat similar seem to have been the customs of the Assyrians and Jews. Among the sculptures unearthed by Layard and others at Nineveh, only two different designs have been noticed for standards; one is of a figure drawing a bow and standing on a running bull, the other of two bulls running in opposite directions (fig. 2). These, says Layard, Mr. Birch supposes may resemble the emblems of war and peace which were attached to the yoke of Darius's chariot. They are borne upon and attached to chariots, which method of bearing these objects was the custom also of the Persians, and prevailed during the Middle Ages. No representations of Egyptian or Assyrian naval standards have been found, but the sails of ships were embroidered and ornamented with devices, which was also a custom during the Middle Ages. In both Egyptian and Assyrian examples, the staff bearing the emblem is frequently ornamented immediately below with flag-like streamers. Rabbinical writers have assigned the different devices of the different Jewish tribes, but the authenticity of their testimony is extremely doubtful. Banners, standards, and ensigns are frequently mentioned in the Bible. "Every man of the children of Israel shall pitch by his standard, with the ensign of their father's house" (Num. ii. 2). "Who is she that looketh forth as the morning, fair as the moon, clear as the sun, and terrible as an army with banners?" (Cant. vi. 10). See also Num. ii. 10, x. 14; Ps. xx. 5, lx. 4; Cant. ii. 4; Is. v. 26, x. 18, lix. 19; Jer. iv. 21.

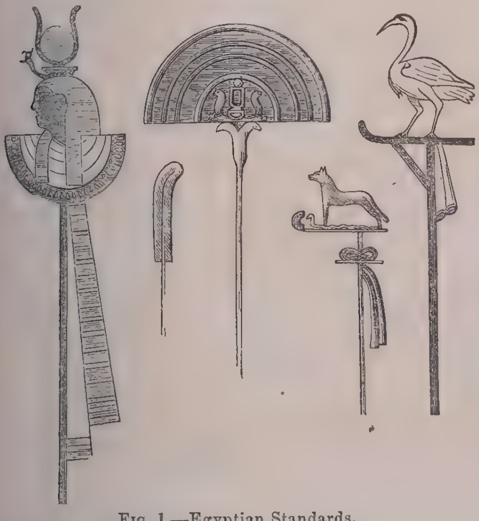

Fig. 1.—Egyptian Standards.

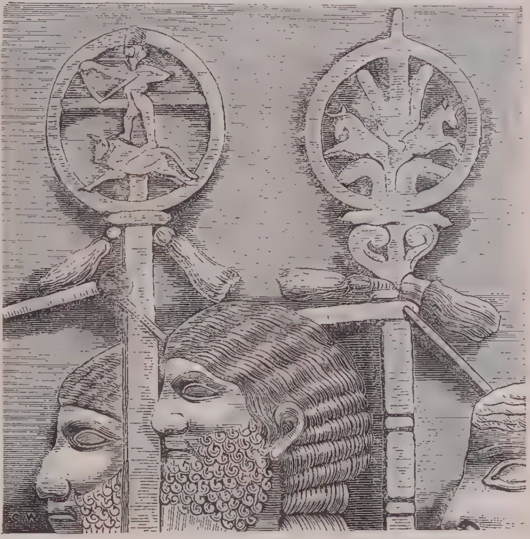

Fig. 2.—Assyrian Standards.

The Persians bore an eagle fixed to the end of a lance, and also represented the sun, as their divinity, upon their standards, which appear to have been formed of some kind of textile, and were guarded with the greatest jealousy by the bravest men of the army. The Carian soldier who slew Cyrus, the brother of Artaxerxes, was allowed the honor of carrying a golden cock at the head of the army, it being the custom of the Carians to wear that bird as a crest on their helmets. The North American Indians carried poles fledged with feathers from the wings of eagles, and similar customs seem to have prevailed among other semi-savage peoples.

The Greeks bore a piece of armor on a spear in early times; afterwards the several cities bore sacred emblems or letters chosen for their particular associations,—the Athenians the olive and the owl, the Corinthians a pegasus, the Thebans a sphinx, in memory of Œdipus, the Messenians their initial M, and the Lacedæmonians Λ. A purple dress was placed on the end of a spear as the signal to advance. The Dacians carried a standard representing a contorted serpent, while the dragon was the military sign of many peoples,—of the Chinese, Dacians, and Parthians among others,—and was probably first used by the Romans as the ensign of barbarian auxiliaries (see fig. 3).

The question of the *signa militaria* of the Romans is a wide and very important one, having direct bearing on the history of heraldry, and on the origin of national, family, and personal devices. With them the custom was reduced to system. "Each century, or at least each maniple," says Meyrick, "had its proper standard and standard-bearers." In the early days of the republic a handful of hay was borne on a pole, whence probably came the name *manipulus*. The forms of standards in later times were very various; sometimes a cross piece of wood was placed at the end of a spear and surmounted by the figure of a hand in silver, below round or oval discs, with figures of Mars or Minerva, or in later times portraits of emperors or eminent generals (fig. 3). Figures of animals, as the wolf, horse, bear, and others, were borne, and it was not until after the time of Marius that the eagle became the special standard of the legion; the *vexillum* was a square piece of cloth fastened to a piece of wood fixed crosswise to the end of a spear, somewhat resembling the mediæval *gonfalon*. The *labarum* of later emperors was similar in shape and fixing, and after Constantine bore the monogram of Christ (fig. 5, A). The Roman standards were guarded with religious veneration in the temples at Rome; and the reverence of this people for their ensigns was in proportion to their superiority to other nations in all that tends to success in war. It was not unusual for a general to order a standard to be cast into the ranks of the enemy, to add zeal to the onset of his soldiers by exciting them to recover what to them was perhaps the most sacred thing the earth possessed. The Roman soldier swore by his ensign.

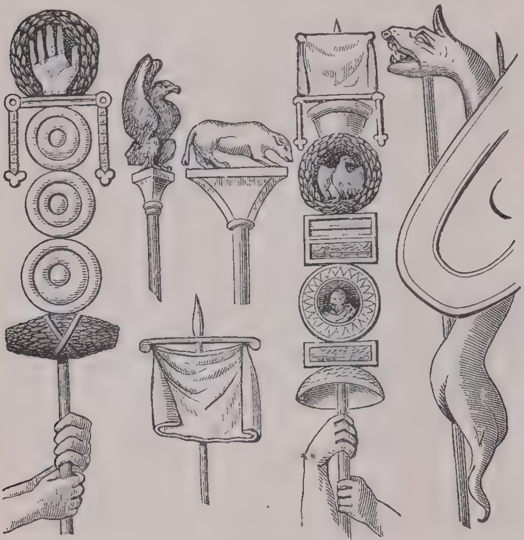

Fig. 3.—Roman Standards.

Although in earlier times drapery was occasionally used for standards, and was often appended as ornament to those of other material, it was probably not until the Middle Ages that it became the special material of military and other ensigns; and perhaps not until the practice of heraldry had attained to definite nomenclature and laws does anything appear which is in the modern sense a flag.

The Bayeux tapestry, commemorating the Norman conquest of England, contains abundant representations of the flags of the period borne upon the lances of the knights of William's army. They appear small in size, and pointed, frequently indented into three points, and bearing pales, crosses, and roundels. One, a Saxon pennon, is triangular, and roundly indented into four points; one banner is of segmental shape and rayed, and bears the figure of a bird which has been supposed to represent the raven of the war-flag of the Scandinavian vikings (fig. 4). These flags and their charges are probably not really significant of the people bearing them; for even admitting that personal devices were used at the time, the figures may have been placed without studied intention, and so give the general figure only of such flags as happened to have come under the observation of the artists. The figures are probably rather ornamental and symbolic than strictly heraldic,—that is, personal devices, for the same insignia do not appear on the shields of the several bearers. The dragon standard which he is known to have borne is placed near Harold; but similar figures appear on the shields of Norman warriors, which fact has induced a writer in the *Journal* of the Archæological Association (vol. xiii. p. 113) to suppose that, on the spears of the Saxons, they represent only trophies torn from the shields of the Normans, and that they are not ensigns at all. Standards in form much resembling these dragons appear on the arch of Titus and the Trajan column as the standards of barbarians.

At the battle of the Standard in 1138, the English standard was formed of the mast of a ship, having a silver pyx at the top, and bearing three sacred banners, dedicated severally to St. Peter, St. John of Beverley, and St. Wilfred of Ripon, the whole being fastened to a wheeled vehicle. Representations of three-pointed, cross-bearing pennons are found on seals of as early date as the Norman era, and the warriors in the first crusade bore three-pointed pennons. It is possible that the three points with the three roundels and cross, which so often appear on these banners, have some reference to the faith of the bearers in the Trinity and in the crucifixion, for in contemporary representations of Christ's resurrection and descent into hell he bears a three-pointed banner with cross above. The triple indentation so common on the flags of this period has been supposed to be the origin of one of the honorable ordinaries—the pile.

The powerful aid of religion seems ever to have been sought to give sanctity to national flags, and the origin of many can be traced to a sacred banner, as is notably the case with the oriflamme of France. The banner of William the Conqueror was sent to him by the pope, and the early English kings fought under the banners of Edward the Confessor and of St. Edmund; while the clumsily blended crosses of St. George, St. Andrew, and St. Patrick still form the national ensign of the three united kingdoms of England, Scotland, and Ireland, whose patron saints they severally were. More secular characters were, however, not uncommon. In 1244 Henry III. gave order for a "dragon to be made in fashion of a standard, of red silk sparkling all over with fine gold, the tongue of which should be made to resemble burning fire and appear to be continually moving, and the eyes of sapphires or other suitable stones." The *Siege of Carlaverock*, an Anglo-Norman poem of the 14th century, describes the heraldic bearings on the banners of the knights present with Edward I. at the siege of that fortress. Of the king himself the writer says—

> "En sa banniere trois luparte
> De or fin estoient mis en rouge;"

and he goes on to describe the kingly characteristics these may be supposed to symbolize. A MS. in British Museum (one of Sir Christopher Barker's Heraldic Collection, Harl. 4632) gives drawings of the standards of English kings from Edward III. to Henry VIII., which are roughly but artistically colored.

The terms for describing a flag are the same as those applied in heraldry to the corresponding parts of a shield. The part of a flag furthest from the point of suspension is called the "fly." The principal varieties of flags borne during the Middle Ages were the pennon, the banner, and the standard; guydhommes, bandirolls, pennoncells, streamers, etc., may be considered as minor varieties. The pennon (fig. 5, B) was a small personal ensign, pointed or swal-

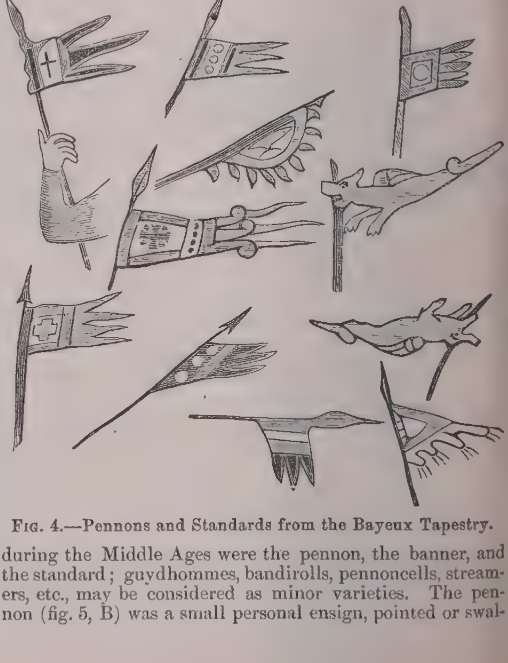

Fig. 4.—Pennons and Standards from the Bayeux Tapestry.

low-tailed, borne below the lance-head of its owner, and charged with his armorial bearings in such a manner that they were in true position when the lance was held horizontally for action. It was a strictly personal flag, and was borne by every knight. Pennons were sometimes charged with the cross of St. George in place of the personal bearings. A manuscript of the 16th century (Harl. 2358) in the British Museum, which gives minute particulars as to the size, shape, and bearings of standards, banners, pennons, guidhommes, pencells, etc., says—"A pennon must be two and a half yards long, made round at the end, and conteyneth the armes of the owner," and warns that "from his standard or streamer a man may flee, but not from his banner or pennon bearing his arms."

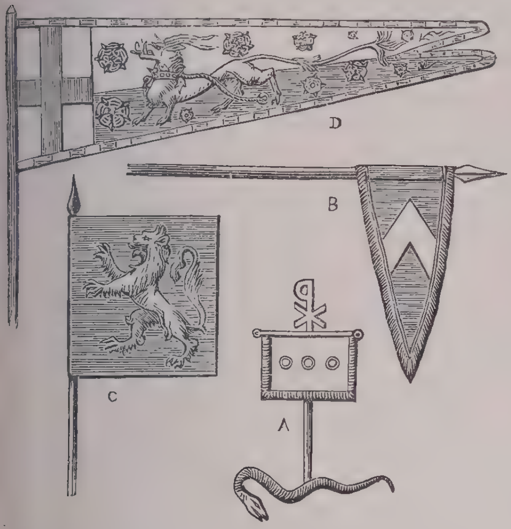

Fig. 5.—A, Labarum from medallion of Constantine; B, Mediæval Pennon; C, Mediæval Banner; D, Standard of Henry V.

The banner (fig. 5, C) was generally about square in form, charged in a manner exactly similar to the shield of the owner, and borne by knights bannerets, and all above them in rank. The rank of knights bannerets was higher than that of ordinary knights, and they could be created on the field of battle only. It was the custom, after a battle, for the king or commander in person to honor a knight who had distinguished himself in the conflict, by tearing off the fly of his knightly pennon, thus creating it a banner and its bearer a banneret. The banner was not a personal ensign but that of a troop. Every baron, who in time of war had furnished the proper number of men to his liege, was entitled to charge with his arms the banner which they followed.

The standard (fig. 5, D) was a large, long flag, gradually tapering towards the fly, varying in size according to the rank of the owner, and generally divided fesse-wise. The shape was not, however, by any means uniform during the Middle Ages, nor were there any definite rules as to its charges. It seems to have been first used by Edward III., the head of whose standard was charged as his shield of arms, and the fly powdered with *fleurs-de-lis* and lions. The Tudor manuscript mentioned above says of the royal standard of that time—"The standard to be sett before the king's pavillion or tente, and not to be borne in battayle; to be in length eleven yards." "Every standard and guydon to have in the chief the cross of St. George, the beast or crest with his devyce and word, and to be slitt at the end." The standard was always borne by an eminent person, and that of Henry V. at Agincourt is supposed to have been carried upon a car, and to have preceded the king. The guidon borne by a leader of horse "must be two yards and a half or three yards long, and therein shall no armes be put, but only the man's crest, cognizance, and devyce." A streamer was a long, tapering flag, and "shall stand in the top of a ship or in the forecastle, and therein be put no armes but a man's conceit or devyce, and may be of length 20, 30, 40, or 60 yards, and is slitt as well as a guydhomme or standard." A pencil was a small streamer-like flag borne by an esquire.

The present royal standard of England was hoisted on the Tower, January 1, 1801, and is thus described:—Quarterly: first and fourth, gules, three lions passant gardant, in pale, or, for England; second, or, a lion rampant, gules, within a double tressure, flory counter flory of the last, for Scotland; third, azure, a harp, or stringed argent, for Ireland. On an escutcheon of pretence were charged the arms of the sovereign's German dominions; but after the accession of Queen Victoria these were removed. This flag is displayed at the main whenever the sovereign or a member of the royal family is on board a ship, and is also hoisted over the royal residence. The Admiralty flag stands next to this in importance, and is red charged, fesse-wise, with an anchor and cable. The national ensign of the United Kingdom, the Union Jack, is the not altogether admirable result of an attempt to combine the several ensigns of the three countries. St. George had long been the patron saint of England, and his banner, argent, a cross gules, its national ensign (fig. 6, A). St. Andrew in the same way was the patron saint of Scotland, and his banner, azure, a saltire argent, the national ensign of Scotland (fig. 6, B). On the union of the two crowns, James I. issued a proclamation that "all subjects of this isle and the kingdom of Great Britain should bear in the main-top the red cross commonly called St. George's cross and the white cross commonly called St. Andrew's cross, joined together according to the form made by our own heralds." This was the first Union Jack (fig. 6, D). After the union with Ireland in 1801 a new ensign was ordered to be prepared which should combine the cross of St. Patrick, a saltire gules on a field argent (fig. 6, C), with the other two. The result was the "meteor flag of England," the present Union Jack (fig. 6, E). It seems to have been produced in considerable contempt of heraldic rules, but excites no less enthusiasm, respect, and obedience on that account. The flag of the lord lieutenant of Ireland is the Union Jack, having in the centre a blue shield charged with a golden harp.

The flags of the United States of America were very various before and after the Declaration of Independence; and even after the introduction of the stars and stripes, these underwent many changes in the manner of their arrangement before taking the position at present established. Historical events have also caused great changes in the standards and national ensigns of France. The ancient kings bore the blue hood of St. Martin upon their standards, and this was succeeded by the oriflamme, which, originally, was simply the banner of the abbey of St. Denis. At what precise period it became the sacred banner of all France is not known, and even its appearance is very differently described in different writers. Guillaume Guiart in his chronicle says—

"Oriflambe est une bannière
De cendal roujoiant et simple
Sanz portraiture d'autre affaire."

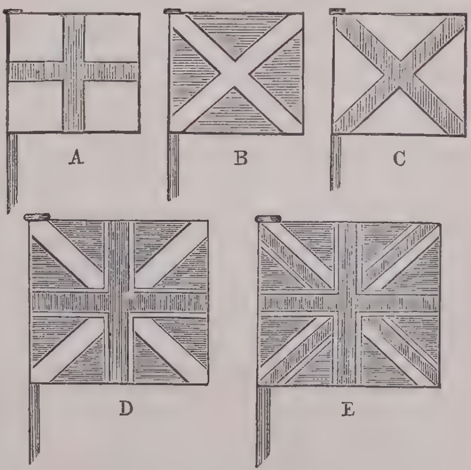

Fig. 6.—A, St. George's Banner; B, St. Andrew's Banner; C, St. Patrick's Banner; D, First Union Jack; E, Present Union Jack.

The oriflamme was succeeded in the 15th century by the white standard powdered with *fleurs-de-lis*, which itself gave place to the standard of the empire, and is the "cornette blanche" for which Chambord contends. The imperial standard was blue, bearing a golden eagle, and powdered with golden bees. The tricolor was introduced at the time of the Revolution, and is divided vertically into three parts, colored blue, white, and red—the red to the fly, and the white in the middle. The origin of this flag and its colors is a disputed question. It is said by some to have been intended to combine the colors of the St. Martin's banner, of the oriflamme, and of the white flag of the Bourbons; by others the colors are said to be those of the city of Paris; and other authorities assert that the flag is copied from the shield of the Orleans family as it appeared after Philip Égalité had knocked off the *fleurs-de-lis*. The present standards and ensigns of existing states are shown in Plate I.

In the British army the standards of the cavalry are the same in color as the regimental facings; they bear the insignia, cipher, number, and honors of the regiment, and are richly ornamented. Those of the household cavalry bear on a crimson field the royal insignia. The colors of each infantry regiment are two in number—the queen's color and the regimental color. The former is the Union Jack variously charged, the latter is in color like the regimental facings, and is charged with the honors, etc., of the corps. The queen's color of the foot guards, however, is crimson, and its regimental color the Union Jack. The royal artillery and the rifles have no colors.

Until 1864 the ships of the British navy bore three different ensigns. In that year, however, her Majesty prescribed the discontinuance of the division of flag officers into those of the red, blue, and white squadrons, and ordered that the white ensign, with its broad and narrow pendants, should be thenceforward established as the colors of the royal naval service, reserving the use of the red and blue colors for special occasions. The white flag with St. George's cross is borne by admirals, vice-admirals, and rear-admirals on their respective masts. The blue ensign is borne by ships in the service of public offices, and also under certain restrictions by such ships as are commanded by officers of the naval reserve. The red ensign is borne by all other British ships. Yacht clubs are allowed, however, certain privileges; they mostly carry the blue ensign with characteristic burgees. An admiral's flag is displayed at the main, a vice-admiral's at the fore, and a rear-admiral's at the mizen truck. Flag officer is another name for admiral, and the flag ship in a fleet is the one carrying the admiral's flag.

At sea the striking of the flag denotes surrender, and the flag of one country being placed over that of another denotes the victory of the former. A yellow flag denotes quarantine. The universally understood flag of truce is pure white.

Flags would obviously suggest themselves for use as signals, and have no doubt always more or less served for the purpose. The numerical systems of Sir Hume Popham and Captain Marryatt were very serviceable but limited in application, the sentences to which the numbers referred being arranged as in a dictionary. By the new commercial code the signals represent consonants, and by means of about a score of flags all the requisite communications can be made. A universal international code of signals would no doubt be a benefit. (W. HE.)

FLAG, or FLOWER DE LUCE, botanically *Iris*, the popular name of a genus of perennial plants of the natural order *Iridaceæ*, occurring in north temperate regions, and having the following characters:—Rootstock creeping, horizontal, thick, with dichotomous joints, or tuberous; leaves usually ensiform and equitant; flowers large and showy; the perianth (see BOTANY, vol. iv. p. 131, fig. 268) superior, with the three outer segments large, spreading or revolute, and frequently bearded at the base, and the three inner smaller, sub-erect, and converging; stamens three, inserted at base of outer segments of perianth, and concealed by the stigmas; anthers extrorse; stigmas three, petaloid, and arching over the stamens; capsule three-celled, dehiscing loculicidally; and seeds numerous, with a fleshy albumen. Many kinds of flag are cultivated in England, but only two species are indigenous. One of these, *Iris Pseudacorus*, the Yellow Flag or Iris, is common in Britain on river banks, and in marshes and ditches. It is called the "Water-flag" or "bastard Floure de-luce" by Gerard, who remarks that "although it be a water plant of nature, yet being planted in gardens it prospereth well." Its flowers appear in June and July, and are of a golden-yellow color. The leaves are from two to four feet long, and half an inch to an inch broad. Towards the latter part of the year they are eaten by cattle. The seeds are numerous and pale-brown; they have been recommended when roasted as a substitute for coffee, of which, however, they have not the properties. The astringent rhizome has diuretic, purgative, and emetic properties, and may, it is said, be used for dyeing black, and in the place of galls for ink-making. The other British species, *I. fœtidissima*, the Fetid Iris, Gladdon, or Roast-beef Plant, the *Xyris* or Stinking Gladdon of Gerard, is a native of England south of Durham, and also of Ireland, southern Europe, and North Africa. Its flowers are usually of a dull, leaden-blue color; the capsules, which remain attached to the plant throughout the winter, are 2 to 3 inches long; and the seeds scarlet. When bruised this species emits a peculiar and disagreeable odor. Among other flags common in Europe are *I. Germanica*, probably the Illyrian iris of the ancients, the purple blossoms of which are a common ornament of English gardens; *I. pallida*, a native of Istria, with pale-blue flowers; and *I. Florentina*, indigenous to the Macedonian coast and Asia Minor, having white flowers. The rhizomes or underground stems of these three species constitute the "orris-root" or *rhizoma Iridis* of pharmacy, formerly known as "ireos" or "orice," which is exported in considerable quantity from southern Europe, more especially from the neighborhood of Leghorn and Trieste. To prepare orris-root the rhizome is in August dug up and freed of its rootlets and brown outer bark; it is then dried, and packed in casks for sale. Orris-root occurs in commerce in whitish, knobby, sometimes branched pieces, of about the thickness of the thumb, and having on one side numerous pits where the rootlets were attached. It has a bitterish and acrid taste, and is purgative and emetic in properties. By drying it acquires the odor of violets. It is exported to India, where it is called *bekhbunufsha* (violet-root). By the ancients it was valued both for its odor and its healing virtues; and in England it was in past times in repute as a medicine for various complaints. Gerard states that "the root of the common Flower de-luce, cleane washed, and stamped with a few drops of Rose water, and laid plaister-wise upon the face of man or woman, doth in two days at the most take away the blacknesse or blewnesse of any stroke or bruse;" he further advocates the use of the same remedy in dropsy and infirmities of the chest. It is now employed in the preparation of violet-powder, and of scented hair and tooth-powders and oils, as a perfume for the breath, for making issue-peas, and occasionally as an errhine. At the risk of causing irritation of the mouth and disturbance of the bowels, it is sometimes given to teething infants to bite. In America the rhizome of *I. versicolor*, the Blue Flag, as also that of *I. Florentina*, is employed as a purgative and alterative in strumous complaints. Orris-root contains, besides gum, ligneous matter, and elliptical granules of starch, an acid resin, *iridin* or *irisin*, precipitable from the tincture by water, and said in small doses to act as a stimulant of the glandular system; also one-twelfth per cent. of a semi-solid substance, the *butter* or *camphor of orris*, which consists apparently of myristic acid with a little essential oil, and which with about 15 parts of spirits forms the *oil* or *essence of orris-root*. According to some writers the blossom of the iris is represented in the well-known heraldic device, the FLEUR-DE-LIS (*q. v.*). The ancient arms of Florence are a red shield bearing a white lily or iris.

The Sweet Flag, or Sweet Sedge, probably the ἄκορον of Dioscorides, is the species *Acorus Calamus*, L., a plant of the natural order *Acoraceæ* or *Orontiaceæ*. It has a wide distribution, growing in wet situations in the Himalayas, North America, Siberia, and various parts of Europe, including England, and has been naturalized in Scotland and Ireland. The leaves are sweet-scented, and are ensiform, equitant, 3 to 6 feet long, and two-thirds to 1½ inches broad; and the spadix is lateral, with bisexual flowers. The rhizome (*rhizoma calami aromatici*), which has a more powerful odor than the herbage, is creeping, horizontal, and woody; it has been employed as an aromatic stimulant, antispasmodic, and tonic. Sir J. E. Smith (*Eng. Flora*, ii. 158, 2d ed., 1828) mentions it as a popular remedy in Norfolk for ague. In India it is used as an insectifuge, and is administered in infantile diarrhœa. It is an ingredient in *pot-pourri*, is employed for flavoring beer, and is chewed to clear the voice; and its volatile oil is employed by makers of snuff and aromatic vinegar. The rhizome of *Acorus Calamus* is sometimes adulterated with that of *Iris Pseudacorus*, which however, is distinguishable by its lack of odor, astringent taste, and dark color.

FLAGELLANTS. The practice of some form of flagellation as a religious observance is of very early origin, and has been more or less followed by nearly every nation, both savage and civilized. Special whipping ceremonies have also had a wide prevalence. According to Herodotus (ii. 40, 61), it was the custom of the ancient Egyptians to beat themselves during or after the sacrifice at the annual festival in honor of their goddess Isis. In Lacedæmon, at the festival of Artemis Orthia or Orthosia, the chief ceremony was that of the Diamastigosis, or flogging of youths before her altar,—a custom which is said to have been introduced by Lycurgus, and which is known to have existed down to the time of Tertullian. From Sparta it spread to other places in Greece, Asia Minor, and Italy (see vol. ii. p. 563). Flagellation was a prominent feature in the Roman festival of the *Lupercalia*, at which it was the custom of the Luperci to run through the most frequented parts of the city, having leathern thongs in their hands, with which they struck all whom they met, the blow being believed to have a salutary influence (see Ovid, *Fasti*, ii. 425 *sqq;* Plutarch, *Cæsar*, 61).

The discipline of flagellation was introduced at a very early period into the Christian Church as a punishment; the first recorded instances of it are isolated cases which happened about the beginning of the 5th century; thus Augustine (*Ep. 159 ad Marcell.*) mentions that in his day flogging was resorted to as a means of discipline, not only by parents and schoolmasters, but also by bishops in their courts; and Joannes Cassianus, writing about the same period, says of offending monks, "vel plagis emendantur vel expulsione purgantur." In the decrees of several provincial councils the practice is referred to as usual and right. But self-flagellation as a voluntary penance was not introduced till a considerably later period. The custom seems to have made but little progress till about the end of the 11th century, when it was largely recommended by the precepts and example of Cardinal Peter Damian; and in the 13th century fraternities were specially formed for its observance as a regular and public religious ceremony. The first of these was instituted about 1210 through the preaching of St. Anthony of Padua, but the new order did not make much progress till about 1260, when, finding a favorable soil in the penitence and fear resulting from the disastrous effects of the long-protracted Guelph and Ghibelline wars in Italy, it suddenly sprung up into vigorous growth through the exhortations and example of Rainer, a monk of Perugia. Great numbers of the inhabitants of this city, noble and ignoble, old and young, traversed the streets, carrying in their hands leathern thongs, with which, according to the chronicle of the monk of Padua, "they drew forth blood from their tortured bodies amid sighs and tears, singing at the same time penitential psalms, and entreating the compassion of the Deity." Many of them soon began a pilgrimage through the neighboring towns, and increasing in numbers as they went, some journeyed through Lombardy into Provence, and others carried the infection to Rome. As they at first effected a considerable improvement in the habits of the people, the religious authorities gave them their countenance; but the Ghibellines, dreading their political influence, prohibited them from entering their territories. Other bands of flagellants visited Bavaria, Bohemia, Austria, Hungary, and Poland, making many converts on their way; but their exhibitions gradually awakened the disgust of the better classes of society, and the tumult and disorder resulting from such large and promiscuous gatherings soon led to their prohibition both by the clergy and the civil rulers. The fraternities again made their appearance after the great plague in the 14th century, this time in Hungary, and spread thence through Germany. From the Continent 120 of them passed over into England, but they were finally obliged to retire without making a single convert. Pope Clement VI. fulminated a bull against the order 20th October, 1349; and the officers of the Inquisition during the papacy of Gregory XI. persecuted them with such vigor that the sect at last disappeared altogether. An attempt made in Thuringia in 1414 by Conrad Schmidt to revive the order under the name of Cryptoflagellants was suppressed by the trial and execution of that leader and the more prominent among his followers. In the 16th century a milder form of the practice was prevalent in France, especially in the southern parts of the kingdom; and in various places flagellating companies were formed, who, however, used the discipline chiefly in private, and only occasionally took part in public flagellating processions. Henry III. of France established a whipping brotherhood in Paris, and himself took part in the processions, but finding that his conduct so far from conferring on him any political benefit awakened only ridicule, he allowed his zeal for self-mortification to abate. The fraternities were suppressed in France by Henry IV., but until recent times the practice of self-flagellation continued to manifest itself intermittently in the south of France, and also in Italy and Spain; and so late as 1820 a procession of flagellants took place at Lisbon.

Geisslergesellschaften*, Halle, 1828, and the article by Dr. Zacher in Ersch and Gruber's *Encyclopädie*.

FLAGEOLET. See FLUTE.

FLAHAUT DE LA BILLARDERIE, AUGUSTE CHARLES JOSEPH, COMTE DE (1785–1870), a French general and diplomatist, was born in Paris on the 21st of April, 1785. His father, a field marshal in the royal army, succeeded Buffon as intendant of the royal gardens, and was guillotined at Arras in 1793. His mother, an ingenious and elegant novel-writer, known as Madame de Souza, from the name of her second husband, the Portuguese author J. M. de Souza-Botelho, emigrated with him to England, and, after he had spent some time in Germany for the sake of his education, brought him back to Paris in 1798. The following year, young Flahaut, being only fifteen years of age, enlisted in a troop of volunteer cavalry, who were to accompany General Bonaparte, then first consul, to Italy. He had a brilliant career, being successively aide-de-camp to Murat, Berthier, and Napoleon. In 1813 he was first gazetted general of brigade, and then general of division, and, although already a count by birth, received a second time this title from the great soldier of fortune, who sought by his simple fiat to create a new empire to be propped up by a new nobility. He was a peer of France during the Hundred Days, and supported with all his influence the project of making Marie-Louise regent, and of thus securing the imperial throne for the young king of Rome under the title of Napoleon II. On the second return of the Bourbons he left France, and lived in exile from 1815 to 1830. In England, his usual place of retreat, he married (28th July, 1817) the daughter of Admiral Keith, who became an Irish peeress as Baroness Keith in 1823, and succeeded to the Scottish barony of Nairn in 1838. By her he had no sons, but several daughters, the eldest of whom married the fourth marquis of Lansdowne. After the revolution of July, 1830, he returned to France, was restored to his former rank in the army, and was made a peer by the Government of Louis-Philippe. He soon became a favorite with the duke of Orleans, the king's eldest son, who gave him a situation of trust in his household. He also received at the same time the dignity of the grand cross of the Legion of Honor of which he had been a commander since 1814. His services as a diplomatist were made use of more than once: he was ambassador at Berlin in 1831, and at Vienna from 1842 until the revolution of 1848. When Louis Bonaparte became Napoleon III., Flahaut de la Billarderie, whose mother had brought up the duke of Morny, did not consider his fidelity as any longer pledged to the Orleans family, and was appointed senator (31st December, 1852). Nor was this the only imperial favor he could boast of. From 1860 until 1862 he was ambassador to London, and, on the 28th of January, 1864, he was promoted to the high dignity of grand chancellor of the Legion of Honor. After that time Flahaut did not play any considerable part in the management of public business. He died on the 1st of September, 1870.

FLAMBARD, RANULPH (RALPH), (d. 1128), bishop of Durham, and justiciar under William Rufus, was a Norman of low birth, who came to England in the train of William the Conqueror in 1066. He took holy orders, obtained several church preferments, and was appointed chaplain to the bishop of London, and made prebendary of St. Paul's. He demanded the deanery also, and this being refused him, he left the bishop's service. He afterwards passed into the service of the king, William II., who made him his chaplain. Ambitious, greedy, and unscrupulous, he flattered and ministered to the vices of his master, and thereby raised himself to the highest places in church and State. To fill the royal coffers he suggested various arbitrary and oppressive measures, by which he earned the hatred of the people, and at the same time the eulogy of the king, that he was the only man who, to please a master, dared to brave the vengeance of mankind. Flambard appears to have been the first to apply the feudal theory to the estates of the church. He suggested that they should be considered as fiefs or benefices held of the king, and that as such at every vacancy they devolved to the crown till the vacancy was supplied. The lesson was quickly learnt, and the immediate consequence was that benefices were kept vacant during the king's pleasure, and refilled only on payment of a large sum of money. It was not till after the death of Lanfranc that the king gave himself up unreservedly to the influence of Flambard. The justiciar obtained for himself the custody of the vacant abbeys of Winchester and Chertsey, the bishopric of Lincoln, and the archbishopric of Canterbury. His extortion and oppressions drew upon him the curses of the clergy as well as of the people, and in 1099 an attempt was made to murder him at sea. But a storm arose and his murderers quarrelled, and Flambard was allowed to land again. He then reappeared at court and was rewarded with the see of Durham. But he was at last "hoist with his own petard;" for at his consecration he had to make the king a present of £1000. On the death of William II., in the following year, the bishop, to satisfy the outcries of the people, was sent to the Tower, "the first man," says Mr. Freeman, "recorded to have dwelled as a prisoner in the Conqueror's fortress." He fared sumptuously in his confinement, treated his keepers, and at length, in February, 1101, managed to escape from the Tower, and fled to Normandy. There he joined Duke Robert, instigated him to the invasion of England, and returned to England with him. He was ultimately restored to his see, and appears to have occupied himself thenceforward with its duties, and in various architectural works—the completion of his cathedral, the building of Norham Castle, and the fortification of Durham. He endowed the college of Christchurch and founded the priory of Mottisford. Flambard died September 5, 1128.

FLAME. An ordinary flame consists of a gas or vapor burning in contact with the air, and in most cases emitting light of greater or less intensity. It is thus distinguishable from the mere incandescence or glow produced by a burning body which does not become gaseous previous to combustion. Many solid substances, however, burn with flame, because under the influence of heat they either, as wood and coal, evolve combustible gases and vapors, or, as zinc, sulphur, and phosphorus, become volatile. Charcoal, although a solid, when brightly heated in a furnace yields flame, since carbon dioxide, or carbonic acid gas, in passing through it, furnishes the combustible gas carbon monoxide, or carbonic oxide. When the air or other supporter of combustion is intimately mixed with the combustible gas, ignition occasions an explosion, and the flame resulting is instantaneous and equally luminous throughout. The dark inner cone of a candle-flame (see BLOWPIPE, vol. iii. p. 728, col. 1) is formed by the volatilized tallow raised by the capillary action of the wick, together with carbonic oxide, carbonic acid gas, and water vapor from the combustion going on in the outer part of the flame, and atmospheric nitrogen, but no free oxygen. By means of a short tube inserted into it, the inner cone of the flame may be made to yield up a portion of its contents; the application of a light to the other end of the tube shows that they are combustible. That within the flame they are not ignited may be demonstrated in many ways. Thus, if a piece of paper be depressed upon the flame for a few seconds, that part of it which touches the central part of the flame is not charred. Again when a platinum wire is held horizontally in a candle flame, it is heated to redness at the two parts where it is in contact with the outer zones of combustion, remaining dark between them. In the intermediate, white-hot, and luminous zone of the candle flame the oxidation of the gases yielded by the inner core is chiefly effected. The reducing effect of the flame is greatest at the surface of contact of these two portions. On account of the slower combustion, the smaller proportion of unoxidized gases, and the greater penetration of oxygen at the upper part of the flame, the luminous zone is thicker, but less bright above than below. In the outer non-luminous zone or mantle, which envelops the whole flame except at its base, combustion is completed. The mantle may be conveniently observed by interposing a small piece of card between the luminous cone and the eye. At the base of the flame, reaching a little upward towards the inner cone, is a light blue zone.

The composition of wax and tallow flames, according to Hilgard, is hydrogen, marsh-gas, olefiant gas, carbon monoxide, carbon dioxide, nitrogen in large proportion, and small quantities of substances condensable to solids or liquids. The same gaseous constituents were found by Landolt in coal-gas, with tetrylene, water, and a very little oxygen. The size of a flame is in relation to the amount of oxygen required to consume a definite bulk of its constituent gas, and to the purity of the oxygen supplied. Hence the flames produced by the same bulk of different gases vary considerably in magnitude, the flame of hydrogen being smaller than that of olefiant gas, but larger than that of a mixture of hydrogen and nitrogen. The flame of oxygen burning in marsh-gas, of which it needs only half its volume for complete combination, is much smaller than that of oxygen burning in hydrogen, of which latter two volumes are required. The tapering shape of a candle-flame results from the spreading of the gases set free in its interior, from the ascent of the products of combustion, owing to their having a higher temperature and consequently a lower density than air, from the currents in the cooler atmosphere around it thereby occasioned, and, lastly, from the exhaustion of combustible material at the upper part of the flame. A flame of large size tends to be irregular in form through variations in the force of air-currents. By altering the atmospheric pressure to which they are subjected, flames may be made to differ considerably in shape. Thus at two atmospheres of pressure the flame of a sperm candle is spike-like, and scarcely one quarter of an inch in diameter below, whilst its upper part is enveloped in smoke, in which the apex is concealed. When the normal pressure is gradually reduced to that of half an atmosphere, the flame is changed in appearance chiefly through diminution of its luminosity; but as the pressure is lowered thence to that of six inches of mercury, the flame becomes globular, and assumes a greenish-blue tint. "Just before the disappearance of the yellow portion of the flame, there comes into view a splendid halo of pinkish light," due probably to incandescent nitrogen, "forming a shell half an inch thick around the blue-green nucleus, and thus greatly enlarging the dimensions of the flame" (Frankland). The color of flames, due, according to Heumann, to heated vapors, is dependent principally on their temperature and on the nature of bodies contained in them. The flame of carbonic oxide, ordinarily blue, is yellowish-red if the gas be heated before ignition. The color of flames is subject also to modification according as one or other of any two gases burnt together is made the supporter of combustion.

Flames may be classed as luminous, such, *e.g.*, as those produced by the burning of wax, tallow, oils, and other carbonaceous substances, and metals; and non-luminous, as those of hydrogen, alcohol, sulphur, and carbon monoxide. A good illuminating flame may readily be procured from a non-illuminant gas by saturating it with the vapor of a heavy hydrocarbon; thus hydrogen and marsh gas, when burnt with one pound of benzol, give a light equal to that yielded by 5·793 ℔ and 7·682 ℔ of spermaceti respectively. The diluents of coal-gas, namely hydrogen, carbon monoxide, and marsh gas, afford practically no light; the light given by the illuminants is not, however, altogether independent of the relative proportions of the diluents (Frankland and Thorne, in *Journ. Chem. Soc.*, March, 1878, p. 94). Flames transparent for all lights are non-luminous, since the power of an incandescent gas at a given temperature to absorb and its power to emit light are proportional to each other.

Sir H. Davy, from experimental investigations, was led to the conclusion that the luminosity of flames is caused by minute solid particles of incandescent carbon or other substances set free from the combustible body by heat. From researches by Frankland and other physicists it appears that this view is not tenable in respect to all flames. The flame of arsenic burning in oxygen emits a remarkably intense white light, although neither the metal nor the product of its combustion, arsenious acid, is gaseous at the temperature of the flame. Again, carbon disulphide and nitric oxide give on combustion together a light which is almost unbearable by the eye, and which, like that of a coal-gas flame, affords a perfectly continuous spectrum, and yet no solid particles are concerned in its production. From these and similar facts, and from the seeming transparency of illuminating flames, it has been concluded by Frankland and others that although a non-luminous flame may be rendered luminous by the introduction into it of substances in the solid condition, *e.g.*, asbestos, platinum wire, and fine powders, the light-giving power of ordinary flames is dependent to a great extent on the density of their constituent gases and vapors, and not on the presence in them of any solid particles. Further, the deposits of soot formed by the flames of ordinary illuminants on bodies with which they come in contact have been regarded as consisting, not of solid carbon set free by the elective affinity of oxygen[1] for the hydrogen of the hydrocarbon, but of mixtures of condensed hydrocarbons of remarkably high boiling-points. The observations of several experimenters do not, however, bear out these conclusions. M. J. L. Soret has demonstrated that the supposed transparency of many flames at high temperatures does not exist, and that at least for ordinary flames Davy's theory of the production of luminosity holds good,—"a pencil of solar light being reflected by diffusion and polarized in precisely the same manner, whether it falls on a very brilliant flame, or whether it illuminates non-incandescent smoke, in which the presence of carbon particles is incontestable" (see *Archives des Science*, July, 1874, trans. in *Phil. Mag.*, 1875). Stein, moreover, has proved that the sooty deposit obtainable from a coal-gas flame contains not more than 9 per cent. of hydrogen, and that, were it merely condensed vapor, exposure to a high temperature would cause its volatilization, which, however, is not the case (see *Journ. Pract. Chem.*, new series, vol. viii. p. 402). Heumann holds that for the production of light from a hydrocarbon flame a high temperature is requisite,—first, to set free solid particles of carbon, and, secondly, to maintain these in a state of incandescence. In support of the theory that the luminosity of hydrocarbon flames does result from the existence within them of carbon particles he points out—

(1) That the luminous mantle of a hydrocarbon flame (as Stein also has proved) is not altogether transparent, the appearance of a continuous image when an object is viewed through the flame being attributable probably to the smallness of the illuminating particles and their rapid motion;

(2) That flames the luminosity of which is due to the presence of finely divided solid matter give shadows when viewed in sunlight; also that luminous hydrocarbon flames give shadows; and that the only light-giving flames that are shadowless are those consisting of glowing gases and vapors;

(3) That chlorine increases the luminosity of feebly luminous hydrocarbon flames by setting free in them particles of what must certainly be pure carbon;

(4) That the presence of solid particles in a hydrocarbon flame may be demonstrated by causing it to impinge upon a heated surface, or upon a similar flame; and

(5) That the lower surface of a small rod placed in a flame becomes covered with soot, which has been separated in the lower portion of the flame. This deposit cannot be the result of the cooling action of the rod, as it is not formed on all sides of the rod, and may be produced on hot as well as cold bodies introduced into the flame.

The influence of pressure upon luminosity has next to be considered. It was shown by Davy in 1817 that the intensity of the light of flames is increased by the condensation and diminished by the rarefaction of the atmosphere. Frankland has proved that flames ordinarily non-luminous, as those of hydrogen, carbonic oxide, and alcohol, can be made highly luminous by condensing the atmosphere in which they burn. Hydrogen yielding, under a pressure of three atmospheres, light estimated at one unit, at twelve atmospheres gives a light of 100 units. On the other hand the flame of arsenic in oxygen loses greatly in luminosity when subjected to reduced pressure. For each decrement of pressure from 30 down to 14 inches of mercury, according to Frankland, the flames of candles undergo an equal or nearly equal loss of luminosity; for lower pressures the diminution is less rapid. The blue portion of the flames of candles burnt on the summit of Mont Blanc was found by the same experimenter to extend to the height of one-eighth of an inch above the cotton, the rate of combustion being the same as at Chamounix; and it has been computed by him that, owing to the difference of barometric pressure in the two cities, the illuminating effects of the same sample of coal-gas in London and Mexico must be in the ratio of 100 to 46·2. From the above-mentioned facts the inference has been drawn that the decrease in light caused by rarefaction of air is attributable to the greater mobility at low pressures, and consequent readier oxidation of gaseous bodies, and also to the increase in the size of the flame. Conversely, the greater luminosity under pressure has been ascribed to the augmentation of the density of the burning gas or vapor thereby occasioned. It has, however, been proved that, although the density of constituents is not without effect on the luminosity of flames, it cannot be considered alone as a cause of this phenomenon, since at high pressures the temperature of a flame is increased. (See Deville, *Compt. Rend.*, lxvii. 1089.) Now, although the light and heat of flames are not related in degree, for the flame of the oxyhydrogen lamp, the hottest known, is scarcely luminous, yet for the same kind of flame luminosity increases with temperature.

The influence of temperature on luminosity may be exemplified in various ways. Thus, if the cooling of a flame be checked by decreasing its surface in respect of its volume, a greater amount of light is obtained. The smoky flame of turpentine becomes luminous when its temperature is raised; and if, by the use of an outer glass cylinder in addition to an ordinary lamp chimney, the air supplying a flame be warmed at the expense of the escaping products of combustion, a considerable increase of light is the result. Heumann finds that the cooling effect of a metallic burner on a gas flame notably diminishes its luminosity; and he attributes the greater intensity of the light observed when the burner is heated to an earlier separation of carbon particles in the flame, and to their more vivid incandescence.

Considerable insight into the conditions of the luminosity of flame has been afforded by experiments with mixtures of illuminating gas and air. The light of pure coal-gas being reckoned at 100 units, that of gas with 10 per cent. of air is 33 units, with 20 per cent. 7, with 30 per cent. 2, and with 40 per cent. 0 (Frankland). The non-luminosity of the flame of the Bunsen lamp, by means of which a mixture of coal-gas with 2 to 2½ times its bulk of air is burnt, has been ascribed by some to the rapid destruction of the illuminants of the gas by the oxygen of the admixed air; but some further explanation of the phenomenon is evidently necessary, since the volume of air employed is inadequate for the complete oxidation of the gas, and the flame is still lightless if hydrogen, carbonic oxide, steam, or indifferent gases, as nitrogen, carbon dioxide, or hydrochloric acid, be substituted for air. Wibel (*Deut. Chem. Ges. Ber.*, viii. 226), finding that the heating of the gas and air previous to ignition renders the flame luminous, concludes that the non-luminosity of the flame is the result of the cooling action of the gases entering it; but, as Heumann points out, it cannot be wholly due to this cause, for the temperature of the non-luminous flame of the Bunsen burner, as also of the blowpipe, is much above that of ordinary flames. From the observations of Stein (*J. Pract. Chem.*, ix. 183), who shows that a flame made non-luminous by nitrogen is yet hot enough to decompose coal-gas, and that carbon monoxide, which has a pyrometric effect nearly equal to that of coal-gas, renders the flame of that gas non-luminous without lowering its temperature, it is evident that the mere introduction of a diluent into a burning gas diminishes its light, independently of any absorption of heat to which it may give rise. Heumann finds that decrease of luminosity through dilution and cooling takes place when a gas-flame giving light in ordinary air is plunged into a mixture of five volumes of air with two volumes of carbon dioxide, or when the products of combustion are allowed to accumulate in the air in which the flame is burning.

---

[1] Compare the action of palladium sponge and foil on various hydrocarbon flames, probably through occlusion of hydrogen. See Wöhler, in *Phil. Mag.*, 1877, p. 35.

The degree of rapidity with which oxidation takes place is a condition which affects very considerably the luminosity of flames. If a small flame, free from unoxidizable substances, be placed in pure oxygen, its light becomes feeble, since the illuminants, instead of spreading through it in an incandescent state, are speedily oxidized; within certain limits, therefore, the mixture with the oxygen of an inert gas, *e. g.*, nitrogen or carbon dioxide, increases the luminosity of the flame. The simplest form of gas-burner, having a single orifice only, affords the minimum amount of light, as the gas rushes without interruption into the air. When, however, as by the use of the fishtail burner, two jets of gas are made to impinge upon each other, the velocity with which the illuminants are driven through the flame and oxidized is retarded, with the effect of considerably augmenting the light. The insertion of a small piece of platinum plate between the two jets, as in Scholl's "platinum perfecter," by reducing still more their velocity, causes a further increase in the luminosity of the flame (Frankland).

The temperature of flames differs considerably according to the conditions of combustion and the nature of the substance burnt. That of hydrogen in air, calculated from its absolute thermal effect as measured by Favre and Silbermann, is 2080° C.; that of carbon monoxide, 2828°; and that of marsh-gas, 1935°. The oxyhydrogen flame has a temperature estimated by Bunsen at 2844° C. The flame of a common candle in its hottest portion is at a temperature high enough to melt a small filament of platinum held in it. Deville, experimenting with a mixture of oxygen and carbon monoxide, found that, at 54 millimetres above the orifice of the burner employed, the flame was hot enough to melt gold; at 12 mm. it melted platinum; and at about 2 mm. lower, at the apex of the inner cone of the flame or a little beneath it, the highest temperature was indicated. The temperature of the flame of alcohol, according to Becquerel, is nearly 1204° C. (2200° Fahr.). M. F. Rossetti (*Journ. de Phys.*, vii. 61), by means of a thermo-electric element of iron and platinum, estimated the temperature of the external envelope of a Bunsen flame at 1350° C., that of the violet portion at 1250°, and that of the blue at 1200°, the temperature in the central dark cone ranging from 250° to 650°. The flame of a mixture of two volumes of illuminating gas with three of carbon monoxide indicated a temperature of 1000°. The determination of the higher temperatures of flame by means of thermo-electricity is, however, open to considerable sources of errors.

The nature and the continuance of the combustion of a flame depend (1) on the supply of the supporter of the combustion; (2) on the ignition-temperature of the gas or vapor; and (3) on the heat produced in burning, and therefore on the degree of rarefaction of the atmosphere, which by lessening chemical combination diminishes the heat of the flame.

(1) In the case of all ordinary flames the oxygen of the air is the supporter of combustion, and of this a free supply is requisite. A combustible hydrocarbon containing more than six parts of carbon to one of hydrogen burns with a smoky flame in air, unless a free draught can be provided by the use of a lamp-glass. A coal-gas flame supplied by an orifice of one quarter of an inch in diameter is not smokeless when higher than 2½ inches; but the flame is rendered clear if by lengthening or dividing the aperture of the jet the exposure of a larger extent of its surface to the air is effected.

(2) Davy (*Phil. Trans.*, 1816, pt. i. p. 117) points out that a large quantity of air thrown upon a small flame lowers its heat below the exploding point of its constituents, and that the extinction of a flame by blowing upon it is probably produced by that cause, assisted by the dilution of the explosive mixture. The fact that, by the presence or neighborhood of a cooler body, the temperature of a heated gas or vapor is lowered beneath the igniting point, explains the action of the wire gauze of the Davy lamp (see COAL, vol. vi. p. 68), and also explains why a candle-flame does not quite touch its wick, or a gas-flame its burner, unless the latter be somewhat strongly heated. The presence of an inactive gas hinders, and if in large quantity prevents, by its cooling action, the explosion of gases. The rate of propagation of ignition in gaseous mixtures thus varies not only with the nature of their combustible constituents, but with the degree to which these are diluted with indifferent gases. The rate in a mixture of hydrogen and oxygen in combining proportions is 34 millimetres a second; and that in a similar mixture of carbonic oxide and oxygen is less than 1 mm. a second (see Bunsen in *Pogg. Ann.*, cxxxi. 165). The maximum velocity of the propagation of ignition for marsh-gas and air, according to M. E. Mallard (*Ann. des Mines*, iii. 355, 1875), is ·524 mm., the minimum ·041 mm. a second; the velocities of coal-gas and air are maximum 1·01 mm. and minimum 0·097 mm. a second. A jet of combustible gas at high pressure, or much diluted with inert gases, can be ignited only at a considerable distance from the orifice at which it issues, owing apparently to the cooling action of the gas itself and of the outer air, and perhaps more especially to the velocity of the gas being greater than that of the propagation of ignition within it (Heumann).

(3) From numerous experiments, chiefly with gases, Davy concluded, first, that the extinction of flame on rarefaction of the atmosphere takes place only when the heat produced by the burning body is insufficient to keep up the combustion, the mere removal of pressure from the burning body being without effect on its combustibility; and secondly, that therefore those bodies which require least heat for their combustion burn in more rarefied air than those requiring more heat, and those which produce much heat in their combustion, other circumstances being the same, burn in more rarefied air than those producing little heat (*Phil. Trans.*, 1817). Hence the extinction of a gas by rarefaction is hindered by raising its temperature. Davy found that a mixture of oxygen and hydrogen in combining proportions could not be exploded when rarefied to one eighteenth of its normal density, and that hydrogen would not burn at a pressure of one-seventh of an atmosphere. Compression tends to make the combustion of flames less perfect, so that flames smoky at ordinary pressure can be rendered smokeless by rarefying the atmosphere in which they are burning.

It has been shown by Professor R. Bunsen that the combustion of a uniform mixture of an inflammable gas with oxygen takes places discontinuously. Thus, when a mixture of carbon monoxide and oxygen in combining proportions is exploded in a closed vessel, its temperature rises from 0° to 3033° C., and two-thirds of the carbon monoxide remains unconsumed and incombustible until, by radiation and conduction, the temperature sinks to 2558° C. Below this temperature a second burning begins, which restores the temperature to 2558° C., at which point it abides stationary until exactly half the carbon monoxide is consumed. The inflamed mixture now cools to 1146° C., when the combustion ceases; it must, however, be afterwards continued at lower as at higher temperatures, since the product of combustion consists eventually, on cooling, of carbon dioxide only. Bunsen has further pointed out that there is a simple molecular relation between the quantities of compounds which, in favorable circumstances, are formed simultaneously in a perfectly uniform gaseous mixture; as, for example, when water and carbon dioxide are produced from hydrogen and carbon monoxide burnt with less oxygen than suffices for the combustion of both. (*Cf.* CHEMISTRY, vol. v. p. 418, col. 2.) This relation undergoes sudden alterations by the addition, by degrees, of a third body, as oxygen, the homogeneous nature of the mixture not being affected. (See *Phil. Mag.* [4], xxxiv. p. 489, 1867.)

The radiation of heat from the flame of a Bunsen burner is considerably less than that from a luminous gas flame, and by most vapors is less powerfully absorbed. The absorption by the air of the heat radiated from a hydrogen flame, the source of which is the aqueous vapor produced by the combustion, has been shown by Tyndall to be due to the presence of moisture in the air, dry air being actually transparent to the radiations of the flame, whereas on humid days undried air may absorb as much as 20·3 per cent. of them. This phenomenon is explicable on the theory that, notwithstanding the high temperature of the flame, there is an accord between its oscillating molecules and those of aqueous vapor at the ordinary temperature, the heat of the flame increasing the amplitude but not the rate of its molecular vibration. When a carbonic oxide flame, the product of which is carbonic acid gas, is made to radiate through an atmosphere of the same gas, the absorption is very great, insomuch that, at a pressure of four inches, 65 per cent. of the radiation is cut off. The radiation of heat from a flame, it is thus apparent, depends on the length of the heat waves to which, according to the nature of its products, it gives rise, and on the character of the atmosphere through which the radiations have to pass. The products of the combustion of alcohol are aqueous vapor and carbonic acid gas, the heat rays of which have a slow period of vibration and correspond to the ultra red rays of the spectrum. The temperature of an alcohol flame may be lowered by plunging into it a spiral of platinum wire, but its heat, being thereby converted into heat of higher refrangibility, is consequently more readily transmitted through some substances, such as glass, than that of the original flame. (See Tyndall, *Heat as a Mode of Motion*, 5th ed., 1875, p. 385 *sq.*)

The phenomena of singing flames have already been alluded to (Acoustics, vol. i. p. 107). M. C. Decharme has produced persistent and varied sounds by directing a jet of air from a tube with a diameter of 3 to 5 mm. on a gas-flame supplied by an orifice of similar diameter. The effect of the jet of air seems to be attributable in great measure to its chemical besides its mechanical action. By altering the diameter and position of the tubes, and the nature and pressure of the gas and air, the sounds and the color and shape of the flame may be greatly modified. (*Compt. Rend.*, lxxx. p. 1602.) On the spectra of flames see Spectrum Analysis.

In consequence of the rarefaction of the air which it occasions, and also its tapering form, flame acts with great rapidity in dissipating a charge of electricity. It has been shown by Grove (*Phil. Mag.*, 1854 [4], vii. 47) that a current of electricity is transmitted in flame, and is produced in it probably by chemical action.

Dr. Edmund Hoppe, in a paper on the electrical resistance of flames (*Nachrichten v. d. K. Ges. d. Wiss. u. d. Georg-Augusts-Universität*, 1877, p. 313), concludes as the result of his experimental investigations that—

> (1) For every flame the electric conductivity increases with an increase of the heat and of the amount of the burning gases; (2) The relative conductivity of different flames is dependent on the nature of the substances burnt; the vapors of salts and solutions are particularly efficient in augmenting the conductivity of the flame of hydrogen; and (3) Ohm's law, contrary to the surmise of Hankel (*Abh. d. Königl. Sächs. Ges. d. Wiss.*, v. p. 72, 1861) is applicable to the case of flames.

The diamagnetism of flame, on its discovery by M. P. Bancalari, was in 1847 investigated both by Zantedeschi and Faraday. When placed in various positions between the poles of a powerful electro-magnet, the flame of a wax taper becomes inclined, or assumes a fishtail shape, or even spreads out right and left in an equatorial direction between the poles, producing a double flame with two long tongues. Faraday found that when a small flame only about one third of an inch high was used, the magnetic force flattened it into an equatorial disc. The brightest flames appeared to him to be the most diamagnetic (Faraday, *Exp. Researches*, vol. iii. pp. 467, 487, 490).

See, in addition to the authorities quoted above, *Works of Sir H. Davy*, ed. by Dr. John Davy, vol. vi. pp. 1–130, 1840; Frankland, *A Course of Lectures on Coal-Gas*, 1867, and *Experimental Researches*, 1877; and Dr. Karl Heumann, *Contributions to the Theory of Luminous Flames*, translated by M. M. Pattison Muir from Liebig's *Ann. der Chemie*, vol. clxxxi. pt. 2, pp. 129–153, and vol. clxxxii. pp. 1–29, in *Phil. Mag.*, 1877, pp. 1, 98, 366. On the transparency of colored flames, see Gouy, *Compt. Rend.*, lxxxvi. 878–880. See also Gas. (F. H. B.)

FLAMEL, Nicolas, a reputed French alchemist, and a caligrapher to the university of Paris, was born about 1330. Becoming a money lender, he amassed immense wealth, with which he built a large number of churches and endowed various charities. He died at Paris 22d March, 1418, and was buried in the church of Saint-Jacques-la-Boucherie, to which he bequeathed the bulk of his property. His unusual prosperity acquired for him, either during his life or shortly after his death, the reputation of being an alchemist, and gradually his history became incrusted with legend. It was said that he accidentally discovered the secret of alchemy in an old book by a Jewish astrologer which happened to come into his hands, and that after reaching a good old age in France, he and his wife mysteriously disappeared, presumably to live in splendor in the East through the aid of the philosopher's stone. A book on alchemy exists in the imperial library of Paris with an inscription professing to have been written by Nicolas Flamel, but plainly a forgery. In 1561, also, a small treatise entitled *Sommaire Philosophique de Nicolas Flamel* was published among a collection of alchemist treatises entitled *Transformation métallique*. These and similar inventions were, however, exploded by Vilain's *Essai sur l'Historie de Saint-Jacques-la-Boucherie*, 1758, which contains an account of the life of Flamel, derived from the archives and other authentic documents of the parish. See also *Description de la Ville de Paris au quinzième Siècle, par Guillebert de Metz*, published for the first time from De Metz's manuscript by Leroux de Lincy, Paris, 1855.

FLAMEN, a Roman sacrificial priest. The flamens were under the direction of the pontifices, and were consecrated to the service of some particular deity. The highest in rank were the Flamen Dialis, Flamen Martialis, and Flamen Quirinalis, who were always selected from among the patricians. When the number of flamens was raised from three to fifteen, those already mentioned were entitled *majores*, in contradistinction to the other twelve, who were called *minores*, and were chosen from the plebs. The flamens were held to be elected for life, but they might be compelled to resign office for neglect of duty, or on the occurrence of some ill-omened event during the performance of their rites. The official dress of the flamens was the *apex* or cap (surmounted with a piece of pointed olive-wood, round the base of which a lock of wool[1] was twisted), the *læna* or mantle, and a laurel wreath. The highest of all these priests was the Flamen Dialis, or flamen of Jupiter, who in virtue of his office was entitled to a lictor, to a seat in the senate, to a curule chair, and to the *toga prætexta*, woven by his wife of thick wool. The sight of fetters being forbidden him, his toga was not allowed to be tied in a knot but was fastened by means of clasps, and the only kind of ring permitted to be worn on his finger was a broken one. If a person in fetters took refuge in his house he was immediately loosed from his bonds; and if a criminal on his way to the scene of his punishment met him and threw himself at his feet he was respited for that day. The flamen Dialis was not allowed to leave the city for a single night, to ride or even touch a horse (a restriction which incapacitated him for the consulship), to swear an oath, to look at an army, or to witness the business of daily life. His marriage was dissoluble only by death. His wife was called flaminica, and was obliged to assist her husband at the sacrifices and other religious duties which he performed. She wore long woollen robes, a purple veil, and shoes made of the leather of sacrificed animals, and, like her husband, she carried the sacrificial knife. Some of the municipal towns in Italy had flamens as well as Rome. When it became customary to deify the emperors, flamens were appointed in all the provincial towns to superintend their worship.

FLAMINGO (Portuguese *Flamingo*, Spanish *Flamenco*), a Water-bird conspicuous for the bright scarlet or flame-colored patch upon its wings, and long known by its classic name *Phœnicopterus* as an inhabitant of most of the countries bordering the Mediterranean Sea, in some of which it is still far from uncommon.[2] Other species have since been discovered, and both its common and scientific names are now used in a general sense. The true position of the Flamingoes (*Phœnicopteridæ*) has been much debated, and ornithologists are as yet by no means agreed upon it. Professor Huxley (*Proc. Zool. Soc.*, 1867, p. 460) considers the form "so completely intermediate between the Anserine birds on the one side, and the Storks and Herons on the other, that it can be ranged with neither."[3] And he puts it by itself as the type of a group *Amphimorphæ* under the larger assemblage of *Desmognathæ*. To the present writer its affinity to the *Anatidæ* seems on many accounts to be the strongest, but that it should stand as a distinct family is manifest.

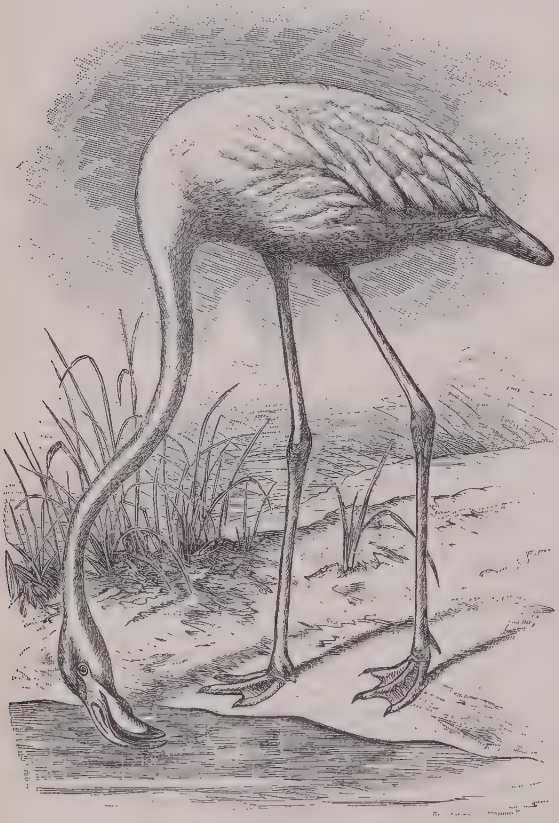
---

[1] *Filum*, whence, according to Varro and Festus, the name flamen, "quasi filamen," was derived.

[2] In Greece and Asia Minor, however, it is rare, and to this cause is most likely to be attributed Aristotle's silence concerning it, though it was known to Aristophanes.

[3] Thus confirming the opinion of Linnæus a century old (*Syst., Nat.*, ed. 12, i. p. 230):—"Medium inter *Anseres et Grallas*, si quis ad præcedentem ordinem referat, forte non errat." He himself places it among the latter.

Though not a few birds have in proportion to the size of their body very long legs and a very long neck, yet the way in which both are employed by the Flamingo seems to be absolutely singular. In taking its food this bird reverses the ordinary position of its head so as to hold the crown downwards and to look backwards. The peculiar formation of the bill, which to the ordinary observer looks as if broken, is, of course, correlated with this habit of feeding, as well as the fact that the *maxilla* is (contrary to what obtains in most birds) not only highly movable, but is much smaller than the *mandibula*—while the latter is practically fixed. Both jaws are, however, beset with *lamellæ*, as in most of the Duck-tribe, and the food is thereby sifted out of the mud as the Flamingo wades with its long neck stretching to the bottom of the shallow waters it frequents. Still more extraordinary is one of the uses made of its long legs. The hen stands upon them[1] while performing that duty which in other birds is rightly called "sitting." This fact was noticed so long ago as 1683 by Dampier, and his statement has been confirmed by the evidence collected by many other travellers. It does not appear, however, that the act has been personally witnessed by any author subsequent to him, and therefore his quaint and obviously truthful account of the way in which Flamingoes build their nests and hatch their young, as observed by him in the Cape Verd Islands, may here be quoted:—"They build their Nests in shallow Ponds, where there is much Mud, which they scrape together, making little Hillocks, like small Islands, appearing out of the Water a foot and half high from the bottom. They make the foundation of these Hillocks broad, bringing them up tapering to the top, where they leave a small hollow pit to lay their Eggs in; and when they either lay their Eggs, or hatch them, they stand all the while, not on the Hillock, but close by it with their legs on the ground and in the water, resting themselves against the Hillock, and covering the hollow Nest upon it with their Rumps: For their Legs are very long; and building thus, as they do, upon the ground, they could neither draw their Legs conveniently into their Nests, nor sit down upon them otherwise than by resting their whole bodies there, to the prejudice of their eggs or their young, were it not for this admirable contrivance, which they have by natural instinct. They never lay more than two Eggs, and seldom fewer. The young ones cannot fly till they are almost full grown, but will run prodigiously fast; yet we have taken many of them."—Dampier, *New Voyage Round the World*, ed. 2, corrected, vol. i. p. 71, London, 1697.



The Flamingo.

It is, of course, only under very favorable circumstances that such nests as these can be built. When time or place is wanting, the hens seem to drop their eggs at random, as Mr. J. W. Clark was told they usually do at this day in the South of France (*Ibis*, 1870, p. 441), where a nest has not been seen for some years. Flamingoes are eminently gregarious. Their favorite resorts are salt-lakes—indeed, these may be said to be a prime necessity; and when, as often happens, they are diminished by drought, the birds have to take long flights in quest of new haunts. Thus some of the wanderers occasionally get separated from the main body, and appear in various unwonted spots. On the wing the Flamingo is described as presenting a singular appearance, its neck and legs being stretched out in a continuous straight line. When feeding or at rest, a flock of these birds, owing to their red plumage, has often been likened to a body of British soldiers. The young appear to be a long time in arriving at the full beauty of their plumage, and as the sexes are said to differ greatly in size, some of the difficulties which the determination of species in this genus presents may be excused. No fewer than four species of *Phœnicopterus* have been described as inhabiting the Old World. There is the large bird known to the ancients, Temminck's *P. antiquorum*, which certainly ranges from the Cape Verd Islands to the Caspian and to India, if not further. The *P. erythræus* of Jules Verreaux has been described as differing in its brighter plumage, and is supposed to be a native of Southern and Western Africa, but it is also said to have strayed to Europe. Then two smaller species (*P. minor*, Geoffroy, and *P. rubidus*, Feilden)—the one from Africa the other from India, have also been described, but whether their existence can be substantiated remains to be seen. Four species have likewise been indicated as belonging to the New World. There is first a large and very brilliantly-colored bird to which the Linnæan name *P. ruber*[2] has been continued, inhabiting suitable localities from Florida southwards to an undetermined latitude. To this species Mr. Salvin (*Trans. Zool. Soc.*, ix. p. 498) refers the *P. glyphorhynchus* of G. R. Gray, founded on a specimen from the Galapagos. Then there is the *P. chilensis* of Gmelin (*P. ignipalliatus* of later writers) which in coloring more resembles the European species, and is found in various parts of South America. Lastly comes the *P. andinus* of Philippi, which is easily distinguished from all others through the want of a back-toe, and was regarded by Bonaparte as meriting generic separation under the name of *Phœnicoparrus*. This appears to have its home on the salt-lakes of the elevated desert of Atacama.

The fossil remains of a Flamingo have been recognized from Lower and Middle Tertiary beds in France, and the species, which appears to have been very close to that commonly called *P. antiquorum*, has received the name of *P. croizeti* from Professor Gervais. But a more interesting discovery is that by Professor A. Milne-Edwards of no fewer than five species of an extinct form of *Phœnicopteridæ*, named by him *Palælodus* (*Ois. Foss. de la France*, ii. p. 58). These are from lacustrine deposits of the Miocene epoch. The same distinguished zoologist also refers to this family remains designated by him *Agnopterus*, and those of the "*Elornis*" (properly *Helornis*) of M. Aymard.

(A. N.)

---

[1] By a mistake, it was before stated (BIRDS, vol. iii. p. 669) that the hen Flamingo "sits astride with dangling legs."

[2] Linnæus referred all the accounts of Flamingoes known to him to a single species, *P. ruber*. Here he was decidedly wrong, since those of the Old World and of the New are entirely distinct; but the reason for assigning this trivial name to one of the latter has yet to be explained by ornithologists.

FLAMININUS, Titus Quinctius, a Roman general and statesman, well known as the liberator of Greece, was born about 228, and died about 174 B. C. The patrician family of the Quinctii had already made their mark in Roman history, but of Titus's immediate ancestors nothing is known except that, according to the Fasti Capitolini, his father bore the same name. He began his public life as a military tribune under Marcellus. On the death of his commander he was appointed proprætor of Tarentum and the neighboring district. His administrative abilities were recognized even in this subordinate post, and in 202 B. C. he was appointed one of a commission of three to supplement the colony of Venuseum, whose numbers had been drained by the war with Hannibal. In 199 B. C. he was made quæstor, and the next year, skipping the regular stages of ædile and prætor, he obtained the consulship, notwithstanding the opposition of the tribunes on account of his youth. The scanty records of his early years furnish nothing which will adequately account for this marvellously rapid promotion, but it is explained and justified by his subsequent career. Flamininus was one of the first and most successful of the rising school of Roman statesmen, the opponents of the narrow and almost provincial patriotism of which Cato was the type, the disciples of Greek culture, and the advocates of a wide imperial policy. His winning manners, his polished address, his knowledge of men, and the personal fascination which was mainly owing to these qualities, and lastly his knowledge of Greek, which, according to Plutarch, he spoke like his native language, all marked him out as the fittest representative of Rome in the East, and it was an auspicious lot for Rome which assigned to the consul the province of Macedonia, and the conduct of the war with Philip. No sooner was he appointed than he set to work to collect new levies, selecting the picked veterans who had served in the Spanish and African campaigns. His predecessors in the province, Sulpicius and Publius, had been dilatory and incompetent, not quitting Rome till their year of office had nearly expired. Flamininus sailed in the early spring, and, leaving his troops at Corcyra to follow him, crossed in a single galley to the mainland and hurried to the Roman camp in Epirus, dismissed his predecessor Publius Vilius, and in a council of war determined to storm the pass of Antigonea, a narrow gorge a little below Clissoura, which was occupied by the enemy. Repulsed in the direct attack, he consented to parley with Philip, and the two commanders met on the banks of the Aous and conversed across the narrow stream. Flamininus at once revealed his intended policy, and in stern and uncompromising terms demanded the liberation of Greece and Thessaly. Philip indignantly broke up the conference, exclaiming that harder terms could not have been proposed to him had he been conquered. This bold attitude of defiance and assertion of the claims of oppressed nationalities was in a great measure the secret of Flamininus's success. The news soon spread that a Roman had come, not to transfer the yoke of slavery, but to vindicate the liberties of Greece. Charops, an Epirot chieftain, revealed to Flamininus a by-path across the mountains by which the pass could be turned; a signal fire showed that the expedition had succeeded; and a simultaneous attack in front and rear completely routed the Macedonians, who were only saved from total destruction by the nature of the ground, which rendered pursuit impossible. Flamininus found himself master of Epirus, and he cemented a lasting friendship with the Epirots by his mildness and moderation, which contrasted with the extortions and ravages of Philip. From Epirus he passed into Thessaly, and took Phaloria, though he was obliged to raise the siege of Atrax on the Peneus. Thence he marched into Locris, where Anticyra served him as a basis for further operations, and enabled him to communicate with the fleet, which was commanded by his brother Lucius. Many towns in Phocis opened their gates to him, and Elatea the capital was taken after a long resistance. His principal efforts were now directed to win over the Achæan league, and in this he was so far successful that a conference of the Greeks was held near Nicæa on the Meliac gulf, under his presidency, to treat with Philip. A truce of two months was agreed to, on condition of the evacuation of all the towns of Phocis and Locris, to enable both parties to send deputies to Rome. The Greek deputies were instructed to demand the expulsion of Macedonian garrisons from Demetrias, Chalcis, and Corinth, as the only guarantee for the freedom of Greece. When the senate demanded of Philip's ambassadors whether he was ready to grant these terms, they replied that they had no instructions, and were sent back and told to treat directly with Flamininus, whose command, which was just expiring, they extended for a second year. Flamininus having thus secured his own object, showed no disposition to temporize with Philip, and the negotiations were abruptly broken off. The perfidy of Nabis, the tyrant of Sparta, secured him a valuable ally and the help of Argos, which Philip had delivered over to Nabis to garrison. Thebes, and with it Bœotia, was gained over partly by persuasion and partly by stratagem, and in the ensuing spring, 197 B.C., Flamininus took the field with nearly all Greece at his back. After a cavalry skirmish near Pheræ, the main armies met at Cynoscephalæ, a low range of hills so called from a fanciful resemblance to dogs' heads. It was the first time that the Macedonian phalanx and the Roman legion had met in open fight, and the day decided which nation was to be master of Greece and perhaps of the world. It was a victory of intelligence over brute force, and where numbers and courage were equally matched, the superior strategy and presence of mind of the Roman general turned the scale. The left wing of the Roman army was retiring in hopeless confusion before the deep and serried ranks of the Macedonian right led by Philip in person, when Flamininus, leaving them to their fate, boldly charged the left wing under Nicanor, which was forming on the heights. The phalanx was like a steam hammer, irresistible if it hit its object, but moving only in one direction, and easily thrown out of gear. Before the left wing had time to form, Flamininus was upon them, and a massacre rather than a fight ensued. This defeat was turned into a general rout by a nameless tribune who collected twenty companies and charged in rear the victorious Macedonian phalanx, which in its pursuit had left the Roman right far behind. 8000 Macedonians were killed and 5000 taken prisoners, while the Romans lost only 700. Macedonia was now at the mercy of Rome, and Flamininus might have dictated what terms he liked, but he showed his usual moderation and farsightedness in disregarding the root-and-branch politics of his Ætolian allies, whose heads were turned by the part they had taken in the victory, and contenting himself with his previous demands. Philip lost all his foreign possessions, but retained his Macedonian kingdom almost entire. Such a valuable bulwark against the outer world of Thracians and Celts was not lightly to be removed. Ten commissioners arrived from Rome to regulate the final terms of peace, and at the Isthmian games which were celebrated at Corinth in the spring of 196 B.C. a herald proclaimed to the assembled crowds that "the Roman people, and T. Quinctius their general, having conquered King Philip and the Macedonians, declare all the Greek states which had been subject to the king henceforward free and independent." A shout of joy arose so loud that it was heard by the sailors in the harbor, and in Plutarch's time the legend told how birds flying over the course had dropped down stunned by the noise. The games were forgotten, and all crowded round the proconsul eager to kiss the hands of the liberator of Greece, who was almost smothered with chaplets and garlands. This day was indeed the climax of Flamininus's career, of which even the stately triumph that two years later he obtained at Rome must have seemed but a pale reflection.

Of the rest of his public life, which was mainly occupied in consolidating the fruits of the victory of Cynoscephalæ, we can only give the barest outline; but we will first attempt to estimate his work, and discuss how far he merited the proud title of benefactor of Greece, which Greeks and Romans alike bestowed on him. That he was animated by an ardent love of the Greek name and race, as genuine as that of Byron, of Canning, or of Kanaris, admits of no reasonable doubt. To attribute to Flamininus a Macchiavellian policy, as if he could have foreseen Corinth overthrown and Achaia turned into a Roman province, is not only disingenuous but absurd. There is more force in the charge which Mommsen brings against him, that his Hellenic sympathies prevented him from seeing the innate weakness and mutual jealousies of the Greek states of that period, whose only hope of peace and safety lay in submitting to the protectorate of the Roman republic. But if the event proved that the liberation of Greece was a political mistake, it was a noble and generous mistake, and reflects nothing but honor on the name of Flamininus.

The only military enterprise that remained after the conquest of Philip was to crush Nabis, who still held Argos, as well as his own tyranny of Sparta. In allowing the conquered tyrant to retain his native possessions, Flamininus was probably influenced by consideration for the Spartans, who would never, except under compulsion, have submitted to the Achæan league.

His last act before returning home is characteristic of the man. Of the Achæans, who vied with one another in showering upon him honors and rewards, he asked but one personal favor, the redemption of the Italian captives who had been sold as slaves in Greece during the Hannibalic war. These to the number of 1200 were presented to him on the eve his departure, and formed the chief ornament of his triumph.

In 192 B.C., on the rupture between the Romans and Antiochus, Flamininus returned to Greece, this time as the civil representative of Rome. His personal influence and skilful diplomacy secured the wavering Achæan states, cemented the alliance with Philip, and contributed mainly to the Roman victory of Thermopylæ. Chalcis and Naupactus, which had joined the enemy, owed their preservation to his interposition with the consul Glabrio. In 189 B.C. he was made censor. In this office his fair fame was sullied by an unseemly quarrel with Cato. Brotherly affection tempted him to shield from just punishment a dissolute and brutal ruffian. In 183 B.C., he undertook an embassy to Prusias, to induce the king of Bithynia to deliver up Hannibal. Hannibal forestalled his fate by taking poison, and his dying words justly stigmatized this pitiful victory over a defenceless and destitute old man. The only excuse for his conduct is that it was prompted not by wanton cruelty or love of revenge,—motives which were wholly alien to his character,—but by restless ambition and an inordinate love of glory, the infirmities of a truly noble nature. The history of his later years is a blank, and we only learn from his biographer Plutarch that his end was peaceful and happy. (F. S.)

FLAMINIUS, Caius, an eminent member of the plebeian gens Flaminia, who in the course of fifteen years of public life (232–217 B.C.) held successively the offices of tribune, prætor, and censor, and was twice advanced to the consular dignity. During his tribuneship (232 B.C.) he was successful in carrying a measure for distributing *viritim* among the plebeians, in terms of the Licinian law, the ager Gallicus Picenus, an extensive tract of newly-acquired territory lying along the east coast of the peninsula to the south of Ariminum. This law was carried in face of the determined opposition of the entire senatorial party, who, according to Valerius Maximus (lib. v. c. 4, sec. 5), at one stage threatened to declare him a public enemy and raise an army against him should he persevere in his agitation. In 227 B.C. he was appointed prætor, Sicily being assigned to him as his province; and there he so conducted himself as to win the lasting gratitude of the people whom he governed. This they took occasion to show thirty years afterwards when his son was curule ædile. In 223 B.C. he was made consul, and, along with his colleague P. Furius Philus, hastened at once to the north to prosecute the Gallic war, which had been occasioned, it is said, by the operation of his own agrarian law, and which had been going on with indecisive results since 225. Rashly crossing the Po near the site of Piacenza, he sustained a check which compelled him to capitulate. The facile Insubres having granted him a free retreat, he speedily, in conjunction with the Cenomani, renewed the attack at another point, perhaps on the river Oglio. On this occasion he was successful; but it seems very doubtful whether the victory was not gained in spite of rather than by means of the generalship of the consul. At all events his conquest of the Insubres failed to make any impression on the aristocratic party who had opposed his election and afterwards sought to obtain his recall; and the honors of a triumph were awarded to him only when the negative decision of the senate had been overborne by the popular voice. According to Plutarch (*Marcellus*, 4) he was nevertheless compelled to resign his office before the natural term had expired. In 221 he was chosen magister equitum under the dictatorship of M. Minucius Rufus, but was not permitted to take office owing to a bad omen—the squeaking of a shrew-mouse—which had occurred immediately after the election. In the following year (220 B.C.) he was censor; and this period of office was marked by the execution of two great public works which are permanently associated with his name—a circus and a road. The Circus Flaminius, erected in a locality which had previously been known as the Prata Flaminia, was designed for the accommodation of the plebeians, especially for their public meetings,—they having no right at that period to sit in the Circus Maximus. The Via Flaminia was the first to be carried across the Apennines, thus connecting the Adriatic and Tuscan seas. It was a continuation of the old military road which had been carried as far as to Spoletium (Spoleto) in 240 B.C. From Spoletium it went to Fulginium (Foligno) and Forum Flaminii (San Giovanni in Forifiamma); thence it mounted the Apennine slope to the station Ad Ensem (La Schieggia), crossing the central ridge at what is now known as the pass of Furlo, and descending by the valley of the Metaurus to Fanum Fortunæ (Fano), whence it kept the coast as far as to Ariminum. In 218 B.C., as a leader of the democratic opposition, Flaminius was one of the chief promoters of the measure brought in by the tribune Claudius, which prohibited senators and senators' sons from possessing sea-going vessels, except such as might be necessary for the transport of the produce of their own estates, and generally shut them out from everything which the Romans included under the category of commercial speculation (quæstus), such as undertaking public contracts (redemptiones), and the like. The effective support which he had given to this measure vastly increased the popularity of Flaminius with his own order, and secured his second election as consul in the following year (217 B.C.), shortly after the defeat of Sempronius at the Trebia. Without staying to go through the usual solemnities of installation at the Capitol, or to celebrate the feriæ Latinæ, Flaminius at once hastened to Ariminum and thence to Arretium, there to be ready for an aggressive campaign against Hannibal as soon as the roads should be open. Meanwhile Hannibal, uneasy in his winter quarters, had accomplished with comparative ease the passage of the Apennines, and forced his way southward across the flooded plains of the lower Arno. The consul, fearing lest the enemy should find Rome unprotected, impetuously set out in pursuit. Free to select his own ground, Hannibal chose to make his stand between Borghetto and Passignano, in the narrow defile formed by the hills of Cortona, which is closed at its entrance by the Trasimene lake. With the main body of his infantry he barred the further outlet at the hill of Torre, while the light troops and the cavalry were posted on the sides of the pass. It was early morning (on the 23d of June, according to the uncorrected calendar, but in reality on some day in April)[1] when Flaminius reached the spot, and a thick haze covering hill and lake altogether concealed the position and even the existence of the enemy, until the Roman army found itself completely and hopelessly surrounded in the fatal defile. In the three hours' carnage that followed 15,000 Romans perished, and Flaminius was among the slain.

From the materials which Livy and Polybius—no friendly critics—furnish, it is manifest that Flaminius was a man of ability, energy, and probity, who with the bravery of a true soldier combined many of the best qualities of a popular democratic leader. While eminent, however, as the head of a political party, and successful in carrying some pieces of useful legislation, he has little or no claim to rank among the greater statesmen of the republic. As a general, moreover, he was headstrong and self-sufficient, and he seems to have owed such victories as he achieved to personal boldness favored by good fortune rather than to any superiority of strategical skill (see Livy, xxi., xxii.; Polybius, ii., iii.).

FLAMINIUS, Caius, son of the preceding, was quæstor under P. Scipio Africanus the elder in Spain in the year 210 B.C., and took part in the capture of New Carthage. Fourteen years later he was curule ædile; and this term of office was marked by the distribution among the citizens at very low prices of large quantities of grain, which in a time of Roman scarcity the Sicilians had sent in grateful remembrance of his father's prætorship thirty years before. In 193 B.C. he himself attained a prætorship, and was sent to the recently constituted province of Hispania Citerior. There he carried on the war against the insubordinate populations, and after a siege took Litabrum, a city which is described by Livy as having been strong and opulent, and made prisoner Corribilo, a powerful chieftain. In 187 B.C. he became consul along with M. Æmilius Lepidus, and was successful in giving peace to Northern Italy by the subjugation of the warlike Ligurian tribes. In the same year the branch of the Via Æmilia (traces of which are still discernible) connecting Bononia (Bologna) with Arretium (Arezzo) was constructed by him.

FLAMSTEED, John, (1646–1719), the first astronomer-royal of England, was born at Denby near Derby, August 14, 1646. He was educated at the free school of that town, where his father carried on business as a maltster. He began the study of mathematics and astronomy while still very young, and showed considerable ingenuity in the construction of mathematical instruments. At the age of fourteen he caught cold while bathing, and he suffered during the rest of his life from a rheumatic affection of the joints. In 1665 he went to Ireland to consult Greatrakes, a notorious quack of the period, who claimed to be able to cure such diseases by manipulation; but he returned to Derby uncured. He continued his astronomical studies here till 1669. About the year 1667 he wrote an able paper on the equation of time, afterwards appended by Wallis to his edition of Horrocks's works. In 1669 he communicated a paper to the Royal Society under the assumed name J. Mathesin a sole fundes, an anagram on his own name Johannes Flamsteedius; but Oldenburg, the secretary, addressed a reply to him, showing that he was discovered, and from that time Flamsteed corresponded with many men of science. Sir Jonas Moore, whose acquaintance he made in 1670 when visiting London, furnished him with several instruments, amongst others with Townly's micrometer. In 1673 Flamsteed composed his treatise on *The true and apparent Places of the Planets when at their greatest and least Distances from the Earth*, a work referred to by Newton in the first edition of his *Principia*. In the same year he obtained his M.A. degree at Cambridge. He does not appear to have ever studied at Cambridge, though his name was entered at Jesus College in 1670, and he resided there for some months in 1674. In this year he published his *Ephemeris*, and drew up a table of the tides. Sir J. Moore at this time proposed to establish Flamsteed in a private observatory at Chelsea; but Charles II., whose attention had been directed to the necessity of improved astronomical tables by a proposal for finding the longitude at sea, determined to establish an observatory, and Flamsteed was appointed "astronomical observator." His observations were made at the queen's house in Greenwich Park, till July, 1676, when the observatory was ready. Of his work as astronomer-royal an account will be found under Astronomy (vol. ii. p. 660). Baily dates the commencement of modern astronomy from the year 1676, when Flamsteed began his observations.

Flamsteed was ill-paid and overworked in his new office. A salary of £100 a year was paid him, and he was left to provide his own instruments. Until 1684 he had to teach two boys from Christ's Hospital, as one of the duties of his post; and he taught other boys, to defray the expenses he incurred for instruments. In 1684 his father died, and he was presented by Lord Keeper North to a small living. His means being thus somewhat improved, he resolved to incur the expense of a mural arc, on the assurance of Government that he would be reimbursed,—a promise which, however, was never fulfilled.

Attention has been drawn since the year 1832 to certain private affairs of Flamsteed's. In that year Francis Baily discovered a large collection of Flamsteed's letters in private hands, and others letters afterwards at Greenwich. The Admiralty unfortunately decided to print these at the public expense. For some it was supposed that the fair fame of Newton and Halley had been darkened by the publication of these documents. But Sir David Brewster discovered among Newton's papers a series of letters and papers completely exculpating Newton and Halley from charges affecting their honor, and placing Flamsteed's character in an unfavorable aspect. It must be remembered, however, that the case made out by Brewster against Flamsteed, and the case made out by Baily against Newton and Halley, both rest on *ex parte* statements. The conclusion to which a careful investigation of both sides of the story appears to point is that both Newton and Flamsteed showed exceeding ill-temper, and that the charges affecting the honor of either (and of Halley as Newton's friend) had their origin entirely in the ill-feeling thus excited. It is unfortunate that the matter should ever have been opened. Let it be remembered only that, while on the one hand Flamsteed furnished Newton with every lunar observation made before 1685, when the first edition of the *Principia* appeared, Newton on the other hand based on these observations the noblest theory the world of science has known.

From 1715 to 1719, the year of his death, Flamsteed superintended the publication of the *Historia Cœlestis*, but the publication was not completed till 1723. His valuable *Atlas Cœlestis* was not published till 1753. The well-known British catalogue of 2884 stars appears in the third volume of the *Historia Cœlestis*. Though of feeble constitution, Flamsteed attained the age of seventy-three, his death occurring on the last day of the year 1719. He was succeeded in the office of astronomer-royal by Halley.

FLANDERS (German *Flandern*, Dutch *Vlaendern*), an ancient countship of the Low Countries, which has left its name to two provinces of the modern kingdom of Belgium, distinguished as East and West. It took its rise about the time of Charles the Great, but the early history of the line of counts is far from certain, the older chronicles giving very different statements. Leaving out of view those mythical personages through whom as a matter of course a connection is established with Priam of Troy, we find the founder of the family of the Foresters, as they are called, in a certain Lideric le Buc, "only son of Saluart prince of Dijon, and of Madame Eringarde daughter of Gerard lord of Roussillon," who, says Lambert, canon of St. Omer, "videns Flandriam vacuam et incultam ac memorosam, occupavit eam." Even Lideric is of doubtful authenticity, though his death in 836 is mentioned in the *Annales Blandinienses*, which were compiled before 1064 from earlier documents. His son Ingelramn, say the chronicles, had a son Audacer; but according to several modern investigators Audacer was merely a cognomen of Baldwin, the next person in the genealogical series. With Baldwin, who is distinguished as *Bras de Fer* or *Iron Arm*, we at length reach the *terra firma* of history. He was a strong, daring, and unscrupulous man, and made noise enough in his own day, more particularly by carrying off and marrying Judith daughter of Charles the Bald of France, a lady of easy principles, who had already been the wife of Æthelwulf of the West Saxons of England, and for a time of Æthelwulf's son Æthelbald. Baldwin II., the Bald, born of this marriage, is mainly remembered as a vigorous opponent of the Normans, and as the builder of the walls of Bruges and Ypres. It is said that he also laid the foundation of the political liberties of his country by appointing twelve of his principal vassals as a council of state. He took to wife Ælfthryth, daughter of King Alfred of England. On his death in 918, his possessions were divided between his two sons Arnulf the Elder and Adolphus; but the latter survived only a short time, and Arnulf succeeded to the whole inheritance. His reign was full of troubles, with the Normans on the one hand, and with the emperor Otho I. on the other; and he made one of his conferences memorable by murdering William Longsword the Norman duke. In his old age he placed the government in the hands of Baldwin, his son by Adela daughter of the count of Vermandois, and the young man, though his reign was a very short one, did a great deal for the commercial and industrial progress of the country, establishing the first weavers and fullers of Ghent, and instituting yearly fairs at Ypres, Bruges, Veurne, Cassel, Courtrai, Thorout, and Rousselare. On Baldwin's death in 961 the old count resumed the control, and spent the few remaining years of his life in securing the succession of his grandson Arnulf or Arnold the younger. The reign of Arnulf was terminated by his death in 989, and he was followed by his son Baldwin IV., styled *Pulchra Barba*, Comely Beard, or simply *Barbatus*, Met den Baerd, With the beard. This Baldwin fought successfully both against the king of France and the emperor Henry II., and obtained from the latter Valenciennes, Walcheren, and the islands of Zealand. The counts of Flanders thus became feudatories of the empire as well as of France. Baldwin's son Baldwin V., surnamed of Lille (in Latin Insularius, in Dutch Van Ryssel), rebelled in 1028 against his father, at the instigation of his wife Adela, daughter of Robert of France; but two years later peace was sworn at Oudenarde, and the old man continued to reign till his death in 1036. Baldwin V. proved a worthy successor, and acquired from the people the title of Debonnaire. He was an active, ambitious, enterprising man, and greatly extended his power by wars and alliances. Before his death he saw his eldest daughter Matilda sharing the English throne with William the Conqueror, his son Baldwin of Mons (in Dutch Bergen) in possession of Hainault in right of his wife Richilde the widow of the late count, and his son Robert the Frisian ruling over the countship of Holland and Friesland in right of the countess Gertrude. His younger daughter Judith had married Tostig, brother of Harold IV. of England. On his death in 1067, Baldwin of Mons succeeded to the countship of Flanders, apparently without opposition on the part of Robert his elder brother; but a few years afterwards a quarrel broke out, and Baldwin was slain. Robert now claimed the tutelage of Baldwin's children, and obtained the support of the emperor Henry IV.; while Richilde, Baldwin's widow, appealed to Philip of France. The contest was decided at Ravenchoven, near Cassel, February 22, 1071, where Robert was victor, and Arnulf III., Baldwin's son, was slain. Arras, Douai, Tournai, and other towns of French Flanders had taken part with the countess and the French, while Ghent, Bruges, Ypres, Courtrai, and other towns of Flanders proper were on the side of Robert. The successful competitor held the countship till his death in 1093, when he was succeeded by his son Robert II., who became famous for his exploits in the first crusade, and acquired the title of Lance and Sword of Christendom. Baldwin VII., surnamed À la Hache, or with the Axe, became count on Robert's death in 1119, and in his turn transmitted the dignity to his cousin Charles of Denmark, son of Canute and Adelais, daughter of Robert the Frisian. This Charles of Denmark was a religious enthusiast, and exercised his authority against all swearers, necromancers, Jews, and usurers. At Bruges in 1127 he ordered all the granaries to be thrown open; and the merchants who had expected to make gain by the dearth were so enraged that they formed a conspiracy and procured his assassination in the church of St. Donat. No fewer than six pretenders to the countship now appeared, and among the rest William Clito, son of Robert Courthose of Normandy, and Thierri or Theodoric of Alsace. The latter was the successful competitor, and he married the widow of Count Charles, Marguerite of Clermont. He distinguished himself at home by the wise encouragement which he gave to the growth of popular liberty, and abroad by the part which he took in several crusading expeditions. In the latter years of his life he retired to Gravelines, leaving the cares of state to his son Philip, who, when he came to rule in his own name, followed in his father's footsteps, and acquired the honorable reputation of "the greatest lawgiver of Flanders." He married Elizabeth of Vermandois, and on her death had a violent dispute with the French monarch about the possession of Vermandois, which was ultimately granted him during his life. As he had no children, his inheritance went to Baldwin of Hainault, who had married his sister Marguerite,—a change of the dynasty which considerably affected the relations of Flanders with France. The French king laid claim to the countship, and Baldwin was constrained to cede Artois, St. Omers, Lens, Hesdin, and a great part of southern Flanders to France, and to allow Matilda of Portugal, the widow of Philip, to hold Lille, Cassel, Veurne, Rille, and Sluys. Marguerite died in 1194 and Baldwin in 1195, and the countship devolved on their son Baldwin IX., who became the founder of the Latin empire at Constantinople, and perished in Bulgaria in 1206. The emperor's two daughters were both under age, and accordingly the government of Flanders and Hainault was entrusted to his brother Philip, assisted by Bosschaert of Avesnes and William of Hainault. Johanna the elder daughter was married to Ferdinand or Ferrand of Portugal, but left no heir; and so the inheritance of both Flanders and Hainault passed on her death in 1279 to the children of the younger, Margaret—the latter to John her eldest son by her first marriage with Bosschaert of Avesnes, and the former to Guy of Dampierre, a son of her second marriage with William of Dampierre, a French nobleman. The government of Guy proved an unfortunate one: Flanders was involved in a severe struggle with France, and for a time almost lost its independence. The old count died at Compiègne in prison about two months after peace was concluded in 1305; and Robert of Bethune, his son, was acknowledged his successor both by the Flemings and by the French. Robert was an able and valiant prince, and has the honor of having established at Bruges the first insurance company. The reign of his grandson and successor Louis of Nevers and Rethel, who had been brought up at the French court and married to Margaret the French king's daughter, was rendered for ever memorable by the enterprise of Jacob van Artevelde, the great hero of Flemish liberty. Louis perished in the battle of Crecy, and left his county to his son Louis II. of Male, near Bruges, under whom the struggle of the Flemish towns for their liberties was maintained. By the marriage of Louis's daughter Margaret with Philip of Burgundy, the lordship of Flanders passed to the Burgundian family; and thus it ultimately became part of the possessions of the house of Austria. The title of count of Flanders has been borne since 1840 by the second son of Leopold I. of Belgium, Philip Eugene Ferdinand.

FLANDRIN, Jean Hippolyte (1809-1864) French painter, was born at Lyons in 1809. His father, though brought up to business, had great fondness for art, and sought himself to follow an artist's career. Lack of early training, however, disabled him for success, and he was obliged to take up the precarious occupation of a miniature painter. Hippolyte was the second of three sons, all painters, and two of them eminent, for the third son Paul is one of the leaders of the modern landscape school of France. Auguste, the eldest, passed the greater part of his life as professor at Lyons, where he died in 1840. After studying for some time at Lyons, Hippolyte and Paul, who had long determined on the step and economized for it, set out to walk to Paris in 1829, to place themselves under the tuition of Hersent. They chose finally to enter the atelier of Ingres, who became not only their instructor, but their friend for life. At first considerably hampered by poverty, Flandrin's difficulties were for ever removed by his taking, in 1832, the Grand Prix de Rome, awarded for his picture of the Recognition of Theseus by his Father. This allowed him to study five years at Rome, whence he sent home several pictures which considerably raised his fame. St. Clair Healing the Blind was done for the cathedral of Nantes, and years after, at the exhibition of 1855, brought him a medal of the first class. Jesus and the Little Children was given by the Government to the town of Lizieux. Dante and Virgil visiting the Envious Men struck with Blindness, and Euripides writing his Tragedies, belong to the Museum at Lyons. Returning to Paris through Lyons in 1838 he soon received commission to ornament the chapel of St. John in the church of St. Séverin at Paris, and reputation increased and employment continued abundant for the rest of his life. Besides the pictures mentioned above, and others of a similar kind, he painted a great number of portraits. The works, however, upon which his fame most surely rests are his monumental decorative paintings. Of these, the principal are those executed in the following churches:—in the sanctuary of St. Germain des Prés at Paris (1842–44), in the choir of the same church (1846–48), in the church of St. Paul at Nismes (1848–49), of St. Vincent de Paul at Paris (1850–54), in the church of Ainay at Lyons (1855), in the nave of St. Germain des Prés (1855–61). In 1856 Flandrin was elected to the Académie des Beaux-Arts. In 1863 his failing health, rendered worse by incessant toil and exposure to the damp and draughts of churches, induced him again to visit Italy. He died of small-pox at Rome on the 21st March, 1864. As might naturally be expected in one who looked upon painting as but the vehicle for the expression of spiritual sentiment, Flandrin had perhaps too little pride in the technical qualities of his art. There is shown in his works much of that austerity and coldness, expressed in form and color, which springs from a faith which feels itself in opposition to the tendencies of surrounding life. He has been compared to Fra Angelico (see FIESOLE); but the faces of his long processions of saints and martyrs seem to express rather the austerity of souls convicted of sin than the joy and purity of never-corrupted life which shines from the work of the early master.

See Delaborde, *Lettres et Pensées de H. Flandrin*, Paris, 1864.

FLANNEL (French *flanelle*, German *Flanel*), an open woollen stuff of various degrees of fineness, from patent flannel, which does not shrink in washing, to baize, which is a coarse woollen stuff, or flannel with a long nap, first introduced into England, together with serge, by the Flemings. Domett is another variety of flannel, the warp of which is made of cotton, and the woof of wool. It is very thin, and is used for linings and for shrouds for coffins. The manufacture of flannel is almost the same as that of other woollen goods, though there are certain wools which are more used for flannel than for any other textiles. For instance, a short staple wool of fine quality from a Southdown variety of the Sussex breed is principally in favor with the flannel-makers at Rochdale, as also the wool from the Norfolk breed, a cross between the Southdown and Norfolk sheep. In Wales the short staple wool of the mountain sheep is used, and in Ireland that of the Wicklow variety of the Cottagh breed. Nearly 2000 persons are employed in this section of woollen manufactures, the chief seat of the industry being Rochdale in Lancashire, while blankets, a special branch of the flannel trade, are extensively woven at Dewsbury in Yorkshire. The wool for these is chiefly obtained from the coarse staples of the Mysore breed in India. Nearly the whole population at Llanidloes and Newton, in Montgomeryshire, finds occupation in flannel weaving, the Welsh flannels having attained a very high reputation. It is also manufactured at Rathdrum, Wicklow, Ireland.

A very considerable trade is carried on by England in flannel, as is shown by the exports for the year 1877, viz:—

	Yards.	Value.
Germany	121,490	£9,167
South Africa	389,834	21,389
Bombay and Scinde	325,510	14,436
Bengal and Burmah	522,080	23,372
Hong Kong	162,640	9,435
Japan	147,760	9,061
Australia	5,817,700	291,451
British North America	1,189,170	50,888
Other countries	597,245	32,193
Total	9,273,429	£466,392

Flannel is highly recommended by medical men as a clothing, both in hot and cold countries, from its properties of promoting insensible perspiration, which, being absorbed by the material, is immediately distributed through the whole thickness of the substance, and thus exposed over a very large surface, to be carried off by the atmosphere. Dr. Black assigns as a reason why flannel and other substances of the same kind keep the body warm, that they compose a rare and spongy mass, the fibres of which touch each other so lightly that the heat moves slowly through the interstices. These being filled up with air, and that too in a stagnant state, give little assistance in conducting the heat.

FLATBUSH, a town of the United States, situated in Kings County, Long Island, New York, about 5 miles from Brooklyn, with which it is connected by tramway lines. Besides the churches, the principal public buildings are an educational institution known as Erasmus Hall, the town-hall, and the county almshouse, hospital, and lunatic asylum. The older houses are noticeable for their palatial style, and the native population is largely of Dutch descent. The battle of Long Island was fought in the neighborhood, August, 1776. Population in 1860, 3471; in 1870, 6309.

FLAT-FISH (*Pleuronectidæ*) is the name common to all those fishes which swim on their side, as the holibut, turbot, brill, plaice, flounder, sole, etc. The side which is turned towards the bottom, and in some kinds is the right in others the left, is generally colorless, and called "blind," from the absence of an eye on this side. The opposite side, which is turned upwards and towards the light, is variously, and in some tropical species even vividly, colored, both eyes being placed on this side of the head. All the bones and muscles of the upper side are more strongly developed than on the lower; but it is noteworthy that these fishes when hatched, and for a short time afterwards, are symmetrical like other fishes, swimming with the body in a vertical position, and. having the eyes placed normally, viz., one on the right and the other on the left side With advancing growth one of the eyes is gradually pushed to the opposite side, and the fish assumes its horizontal position in the water. Flat fishes are bottom-fish, rarely rising to the surface, and apparently not descending to very great depths. They are found in all seas, except perhaps the highest latitudes. More than 200 species are known; they are most numerous towards the equator, whilst those of the largest size (holibut) occur in the temperate and cold regions. Some enter fresh water freely, like the flounder. The size and abundance of the flat-fish, and the flavor of their flesh, render this family one of the most useful and economically important. See ICHTHYOLOGY.

FLAVEL, JOHN (*c.* 1627–1691), an English nonconformist divine, was born at Bromsgrove in Worcestershire, probably in 1627. He was the elder son of Mr. Richard Flavel, described in contemporary records as "a painful and eminent minister." After receiving his early education, partly at home, and partly at the grammar-schools of Bromsgrove and Haslar, he entered University College, Oxford. Soon after taking orders in 1650, he obtained a curacy at Deptford, and on the death of the vicar he was appointed to succeed him. From Deptford he removed in 1656 to Dartmouth. He was ejected from his living by the passing of the Act of Uniformity in 1662, but continued to preach and administer the sacraments privately till the Oxford Act of 1665, when he retired to Slopton, five miles from the scene of his official labors. After the expulsion of the Stuart dynasty, he became minister of a nonconformist church at Dartmouth, where he labored till his death in 1691. Although the writings of Flavel now appear cumbrous in structure, yet their literary style has some merits; and from their tender and devotional character they were long popular with a certain class of readers.

His principal works are his *Treatise on the Soul of Man; The Fountain of Life, in forty-two Sermons; The Method of Grace; A Token for Mourners; Husbandry Spiritualized;* and *Navigation Spiritualized.* A new edition of his collected works was published in 1820 in 6 vols., 8vo. His select works were published in 1823 in 2 vols., and an edition of these, with life, in 1833.

FLAVIAN I., patriarch of Antioch, was born about 320, most probably in Antioch. He lost his parents in early youth, and, although inheriting great wealth, he renounced a life of worldly ease, and resolved to devote his riches and his talents to the service of the church. In association with Diodorus, afterwards bishop of Tarsus, he supported the catholic faith against the Arian Leontius, who had succeeded Eustathius as patriarch of Antioch. The two friends assembled their adherents outside the city walls for the observance of the exercises of religion; and, according to Theodoret, it was in these meetings that the practice of antiphonal singing was first introduced in the services of the church. When Meletius was appointed patriarch of Antioch in 361, he raised Flavian to the priesthood, and on the death of Meletius in 381, Flavian was chosen, by a majority of the bishops, to succeed him. The schism between the two parties was, however, far from being healed, and Paulinus, who by the extreme Eustathians had been elected patriarch in opposition to Meletius, still exercised authority over a portion of the church. On the death of Paulinus in 383, Evagrius was chosen as his successor, and after the death of Evagrius in 395 the Eustathians still continued to hold separate meetings; but through the intervention of Chrysostom of Constantinople, they agreed, about the year 399, to acknowledge Flavian as their bishop. During the patriarchate of Flavian a serious sedition occurred in the streets of Antioch (387), and the statues of Theodosius and the empress were overturned; but Flavian went to Constantinople, and by an eloquent discourse, prepared for him, it is said, by his pupil St. John Chrysostom, succeeded in averting the emperor's vengeance from the city. Flavian died in 404.

FLAVIAN II., patriarch of Antioch, was chosen by the emperor Anastasius I. to succeed Palladius, most probably in 498. He endeavored to please both parties by steering a middle course in reference to the Chalcedon decrees, but was induced after great hesitation to agree to the request of Anastasius that he should accept the Henoticon. His doing so, while it brought upon him the anathema of the patriarch of Constantinople, failed to secure a return of the favor of Anastasius, who in 511 found in the riots which were occurring between the rival parties in the streets of

Antioch a pretext for deposing Flavian, and banishing him to Petra, where he died in 518. Flavian was soon after his death enrolled among the saints of the Greek Church, and after some opposition he was also canonized by the Latin Church.

FLAVIAN, patriarch of Constantinople, succeeded Proclus in 447. He presided at the council which deposed Eutyches in 448, but in the following year he was deposed by the council of Alexandria, which reinstated Eutyches in his office. Not satisfied with the mere deposition of Flavian, his opponents were so carried away by their feelings as to proceed to personal violence, and his death soon after at Hypæpa in Lydia is attributed to a kick inflicted on him by Dioscorus, patriarch of Alexandria, the president of the council. The council of Chalcedon canonized him as a martyr, and he is also enrolled in the martyrology of the Latin Church, his day being the 18th February.

FLAVIGNY, VALERIEN, was born near Laon about the beginning of the 17th century. Having studied in the college of Sorbonne, he received from it his doctor's diploma in 1628, and shortly afterwards obtained a canonry in the cathedral of Rheims. In 1630 he became professor of Hebrew in the college of France. He died at Paris, 29th April, 1674. The works of Flavigny are chiefly occupied with discussions regarding the Hebrew text of the Bible. His opinions acquired him for a time considerable celebrity, and engaged him in controversies with some of the doctors of the Sorbonne, but now possess scarcely any interest.

The following are his principal treatises:—*Epistolæ IV. de ingenti Bibliorum opere septemlingui*, 1636; *Epistolæ duæ in quibus de ingenti Bibliorum opere quod nuper Lutetiæ Parisiorum prodiit*, etc., 1646; *Epistola III*^{a} *in qua de libello Ruth Syriaco, quem Abr. Echellensis insertum esse voluit ingenti Bibliorum operi*, 1647; *Epistola adversus Abr. Echellensem de libello Ruth*, etc., 1648; *Disquisitio Theologica*, etc., 1666. He also published an edition of the works of William of Saint-Amour, a doctor of the 13th century.

FLAVIN is an extract or preparation of quercitron bark (*Quercus tinctoria*), used as a yellow dye in place of the ground and powdered bark. Flavin is not a definite chemical compound, and the commercial product is found to vary greatly in composition and tinctorial value, according, probably, to the nature of the varied processes employed in its preparation. The manufacture of flavin is principally carried on in the United States under various patents; and while some kinds appear to be little other than finely powdered and sifted bark, others are almost pure quercitrin, the chemical principle peculiar to quercitron bark. A kind of flavin made in England is obtained by exhausting the bark in a weak alkaline solution, and precipitating the coloring matter by neutralization with either sulphuric acid or hydrochloric acid. Flavin of good quality ought to possess about 16 times the tinctorial strength of the bark from which it is extracted.

FLAX. The terms flax or lint (German *Flachs*, French *Lin*, Latin *Linum*) are employed at once to denote the fibre so called, and the plant from which it is prepared. The flax plant (*Linum usitatissimum*) belongs to the natural order *Linaceæ*, and like most plants which have been long under cultivation, it possesses numerous varieties, while the wild or parent condition is not known. As cultivated it is an annual with an erect stalk rising to a height of from 20 to 40 inches, with alternate, sessile, linear-lanceolate leaves, branching only at the top into a corymbose panicle of bright blue flowers. The flowers are regular and symmetrical, having five ovate-acute, slightly ciliate sepals, five deciduous petals, and a syncarpous pentacarpellary ovary with five distinct styles. The fruit or boll is round, containing five cells or loculaments, each of which is divided into two by a spurious dorsal dissepiment, thus forming ten divisions, each of which contains a single seed. The seeds, well known as linseed, are flat, oval in form, dark brown in color, with a smooth shining mucilaginous coat, and flat oily cotyledons. There are several other species which have been and are cultivated to an inconsiderable extent as sources of fibre, as the Greek or spring flax (*L. crepitans*) Siberian flax (*L. perenne*), and the white blossomed or purging flax (*L. catharticum*), all grown in certain parts of Austria, and the narrow-leaved flax (*L. angustifolium*), which was utilized at a very remote period.

The cultivation and preparation of flax are the most ancient of all textile industries, very distinct traces of their existence during the stone age being preserved to the present day. "The use of flax," says Keller (*Lake Dwellings of Switzerland*, translated by J. E. Lee), "reaches back to the very earliest periods of civilization, and it was most extensively and variously applied in the lake dwellings even in those of the stone period. But of the mode in which it was planted, steeped, heckled, cleansed, and generally prepared for use, we can form no idea, any more than we can of the mode or tools employed by the settlers in its cultivation. . . . Rough or unworked flax is found in the lake dwellings made into bundles, or what are technically called heads, and, as much attention was given to this last operation, it was perfectly clean and ready for use." As to its applications at this early period, Keller remarks—"Flax was the material for making lines and nets for fishing and catching wild animals, cords for carrying the earthenware vessels and other heavy objects; in fact one can hardly imagine how navigation could be carried on, or the lake dwellings themselves be erected, without the use of ropes and cords; and the erection of memorial stones (menhirs, dolmens) at whichever era, and to whatever people these monuments may belong, would be altogether impracticable without the use of strong ropes." As to the variety of flax cultivated by the prehistoric races, Dr. Heer is of opinion that it was the small-leaved flax (*Linum angustifolium*), a plant native of the Mediterranean coasts from Greece and Dalmatia to the Pyrenees.

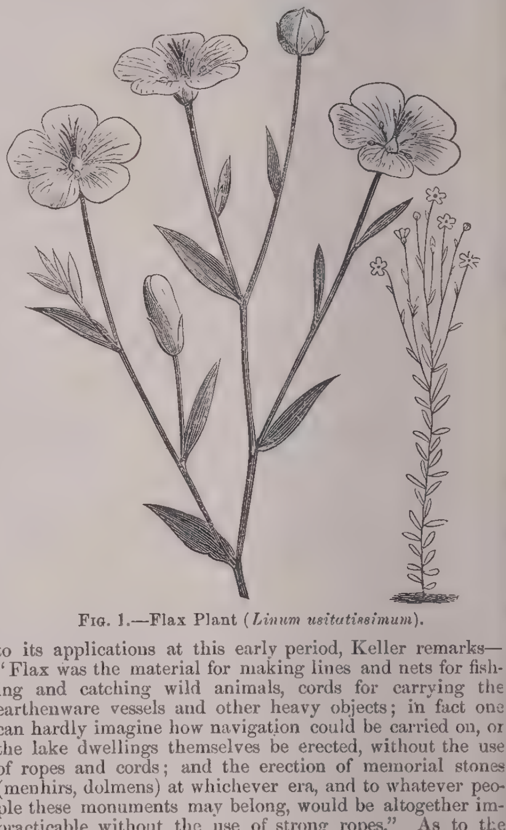

FIG. 1.—Flax Plant (*Linum usitatissimum*).

That flax was extensively cultivated and was regarded as of much importance at a very early period in the world's history there is abundant testimony. Especially in ancient Egypt the fibre occupied a most important place, linen having been there not only generally worn by all classes, but it was the only material the priestly order was permitted to wear, while it was most extensively used as wrappings for embalmed bodies and for general purposes. In the Old Testament we are told that Pharaoh arrayed Joseph "in vestures of fine linen" (Gen. xlii. 42), and among the plagues of Egypt that of hail destroyed the flax and barley crops, "for the barley was in the ear, and the flax was bolled" (Exod. ix. 31). Further, numerous pictorial representations of flax culture and preparation exist to the present day on the walls of tombs and in Egypt. Sir J. G. Wilkinson in his description of ancient Egypt shows clearly the great antiquity of the ordinary processes of preparing flax. "At Beni Hassan," he says, "the mode of cultivating the plant, in the same square beds now met with throughout Egypt (much resembling our salt pans), the process of beating the stalks and making them into ropes, and the manufacture of a piece of cloth are distinctly pointed out." The preparation of the fibre as conducted in Egypt is illustrated by Pliny, who says—"The stalks themselves are immersed in water, warmed by the heat of the sun, and are kept down by weights placed upon them, for nothing is lighter than flax. The membrane, or rind, becoming loose is a sign of their being sufficiently macerated. They are then taken out and repeatedly turned over in the sun until perfectly dried, and afterwards beaten by mallets on stone slabs. That which is nearest the rind is called *stupa* ['tow'], inferior to the inner fibres, and fit only for the wicks of lamps. It is combed out with iron hooks until the rind is all removed. The inner part is of a whiter and finer quality. Men are not ashamed to prepare it" (Pliny, *N. H.*, xix. 1). For many ages, even down to the early part of the 14th century, Egyptian flax occupied the foremost place in the commercial world, being sent into all regions with which open intercourse was maintained. Among Western nations it was, without any competitor, the most important of all vegetable fibres till towards the close of the 18th century, when, after a brief struggle, cotton took its place as the supreme vegetable fibre of commerce.

Flax, as a field crop, having been described under the heading AGRICULTURE (see vol. i. p. 337), it is unnecessary to dwell here on that feature of the subject. When flax is cultivated primarily on account of the fibre, the crop ought to be pulled before the capsules are quite ripe, when they are just beginning to change from a green to a pale brown color, and when the stalks of the plant have become yellow throughout about two-thirds of their height. The various operations through which the crop passes from this point till flax ready for the market is produced are—(1) pulling, (2) rippling, (3) retting, and (4) scutching.

Pulling and *rippling* may be dismissed very briefly. Flax is always pulled up by the root, and under no circumstances is it cut or shorn like cereal crops. The pulling ought to be done in dry clear weather; and care is to be taken in this, as in all the subsequent operations, to keep the root-ends even, and the stalks parallel. At the same time it is desirable to have, as far as possible, stalks of equal length together,—all these conditions having considerable influence on the quality and appearance of the finished sample. As a general rule the removal of the "bolls" or capsules by the process of *rippling* immediately follows the pulling, the operation being performed in the field; but under some systems of cultivation, as, for example, the Courtrai method, alluded to below, the crop is made up into sheaves, dried, and stacked, and is only bolled and retted in the early part of the next ensuing season. The best rippler, or apparatus for rippling, consists of a kind of comb having, set in a wooden frame, iron teeth made of round-rod iron three-sixteenths of an inch asunder at the bottom, and half an inch at the top, and 18 inches long, to allow a sufficient spring, and save much breaking of flax. The points should begin to taper 3 inches from the top. A sheet or other cover being spread on the field, the apparatus is placed in the middle of it, and two ripplers sitting opposite each other, with the machine between them, work at the same time. It is unadvisable to ripple the flax so severely as to break or tear the delicate fibres at the upper part of the stem. The two valuable commercial products of the flax plant, the seeds and the stalk, are separated at this point. We have here to do with the latter only.

Retting or *rotting* is an operation of the greatest importance, and one in connection with which in recent years numerous experiments have been made, and many projects and processes put forth, with the view of remedying the defects of the primitive system or altogether supplanting it. From the earliest times two leading processes of retting have been practised, termed respectively water-retting and dew-retting; and as no method has yet been introduced which satisfactorily supersedes these operations, they will first be described.

Water-retting.—For this—the process by which flax is generally prepared—pure soft water, free from iron and other materials which might color the fibre, is essential. Any water much impregnated with lime is also specially objectionable. The dams or ponds in which the operation is conducted are of variable size, but should be not more than 4 feet in depth. It is calculated that a dam 50 feet long, 9 feet broad, and 4 feet deep is sufficient to ret the produce of an acre of flax. The rippled stalks are tied in small bundles and packed, roots downwards, in the dams till they are quite full; over the top of the upper layer is placed a stratum of rushes and straw, or sods with the grassy side downwards, and above all stones of sufficient weight to keep the flax submerged. Under favorable circumstances a process of fermentation should immediately be set up, which soon makes itself manifest by the evolution of gaseous bubbles. After a few days the fermentation subsides; and generally in from ten days to two weeks, the process ought to be complete; but everything depends upon the weather; and as the steeping is a critical operation, it is essential that the stalks be frequently examined and tested as the process nears completion. When it is found that the fibre separates readily from the woody "shive" or core, the beets or small bundles are ready for removing from the dams. It is next spread, evenly and equally, over a grassy meadow, where it is left for about a fortnight, at the end of which time the fibres will have partly separated from the core and "bowed." At this point advantage is taken of fine dry weather to gather up the flax, which is now ready for scutching, but the fibre is improved by stooking and stacking it for some time before it is taken to the scutching mill.

Dew-retting is the process by which all the Archangel flax and a large portion of that sent out from St. Petersburg are prepared. By this method the operation of steeping is entirely dispensed with, and the flax is, immediately after pulling, spread on the grass where it is under the influence of air, sun-light, night-dews, and rain. The process is tedious, the resulting fibre is brown in color, and it is said to be peculiarly liable to undergo heating (probably owing to the soft heavy quality of the flax) if exposed to moisture and kept close packed with little access of air. Archangel flax is, however, peculiarly soft and silky in structure, although in all probability water-retting would result in a fibre as good or even better in quality.

The theory of retting, according to the investigations of J. Kolb, is that a peculiar fermentation is set up under the influence of heat and moisture, resulting in a change of the intercellular substance—pectose or an analogue of that body—into pectin and pectic acid. The former, being soluble, is left in the water; but the latter, an insoluble body, is in part attached to the fibres, from which it is only separated by changing into soluble metapectic acid under the action of hot alkaline ley in the subsequent process of bleaching.

To a large extent retting continues to be conducted in the primitive fashions above described, although numerous and persistent attempts have been made to improve upon it, or to avoid the process altogether. The uniform result of all experiments has only been to demonstrate the scientific soundness of the ordinary process of water-retting, and all the proposed improvements of recent times seek to obviate the tediousness, difficulties, and uncertainties of the process as carried on in the open air. In the early part of the present century much attention was bestowed, especially in Ireland, on a process invented by Mr. James Lee. He proposed to separate the fibre by purely mechanical means without any retting whatever; but after the Irish Linen Board had expended many thousands of pounds and much time in making experiments and in erecting his machinery, his entire scheme ended in complete failure. About the year 1851 Chevalier Claussen sought to revive a process of "cottonizing" flax—a method of proceeding which had been suggested three-quarters of a century earlier. Claussen's process consisted in steeping flax fibre or tow for twenty-four hours in a weak solution of caustic soda, next boiling it for about two hours in a similar solution, and then saturating it in a solution containing 5 per cent. of carbonate of soda, after which it was immersed in a vat containing water acidulated with a half per cent. of sulphuric acid. The action of the acid on the carbonate of soda with which the fibre was impregnated caused the fibre to split up into a fine cotton-like mass, which it was intended to manufacture in the same manner as cotton. A process to turn good flax into bad cotton had, however, on the face of it, not much to recommend it to public acceptance; and Claussen's process therefore remains only as an interesting and suggestive experiment.

The only modification of water-retting which has hitherto endured the test of prolonged experiment, and taken a firm position as a distinct improvement, is the warm-water retting patented in England in 1846 by an American, Robert B. Schenck. For open pools and dams Schenck substitutes large wooden vats under cover, into which the flax is tightly packed in an upright position. The water admitted into the tanks is raised to and maintained at a temperature of from 75° to 95° Fahr. during the whole time the flax is in steep. In a short time a brisk fermentation is set up, gases at first of pleasant odor, but subsequently becoming very repulsive, being evolved, and producing a frothy scum over the surface of the water. The whole process occupies only from 50 to 60 hours. A still further improvement, due to Mr. Pownall, comes into operation at this point, which consists of immediately passing the stalks as they are taken out of the vats between heavy rollers over which a stream of pure water is kept flowing. By this means, not only is all the slimy glutinous adherent matter thoroughly separated, but the subsequent processes of breaking and scutching are much facilitated.

A process of retting by steam was introduced by W. Watt of Glasgow in 1852, and subsequently modified and improved by J. Buchanan. The system possessed the advantages of rapidity, being completed in about 10 hours, and freedom from any noxious odor; but it yielded only a harsh, ill-spinning fibre, and consequently failed to meet the sanguine expectations of its promoters.

In connection with improvements in retting, Mr. Michael Andrews, the energetic secretary of the Belfast Flax Supply Association, has made some suggestions and experiments which deserve close attention. In a paper contributed to the International Flax Congress at Vienna in 1873, he entered into details regarding an experimental rettery he had formed, with a view of imitating by artificial means the best results obtained by the ordinary methods. In brief, Mr. Andrews's method consists in introducing water at the proper temperature into the retting vat, and maintaining that temperature by keeping the air of the chamber at a proper degree of heat. By this means the flax is kept at a uniform temperature with great certainty, since even should the heat of the air vary considerably through neglect, the water in the vat only by slow degrees follows such fluctuations. "It may be remarked," says Mr. Andrews, "that the superiority claimed for this method of retting flax over what is known as the 'hot-water steeping' is uniformity of temperature; in fact the experiments have demonstrated that an absolute control can be exercised over the means adopted to produce the artificial climate in which the vats containing the flax are situated."

Scutching is the process by which the fibre is freed from its woody core and rendered fit for the market. For ordinary water-retted flax two operations are required, first *breaking* and then *scutching*, and these are done either by hand labor or by means of small scutching or lint mills, driven either by water or steam power. Hand labor, aided by simple implements, is still much used in Continental countries; but the use of scutching mills is now very general, these being more economical, and turning out flax of a much better quality. The breaking is done by passing the stalks between grooved rollers, to which in some cases a reciprocating motion is communicated, and the broken shives are beaten out by suspending the fibre in a machine fitted with a series of revolving blades, which, striking violently against the flax, shake out the bruised and broken woody cores. A great many modified scutching machines and processes have been proposed and introduced with the view of promoting economy of labor and improving the turn-out of fibre, both in respect of cleanness and in producing the least proportion of codilla or scutching tow.

The celebrated Courtrai flax of Belgium is the most valuable staple in the market, on account of its fineness, strength, and particularly bright color. There the flax is dried in the field, and housed or stacked during the winter succeeding its growth, and in the spring of the following year, it is retted in crates sunk in the sluggish waters of the river Lys. After the process has proceeded a certain length, the crates are withdrawn, and the sheaves taken out and stooked. It is thereafter once more tied up, placed in the crates, and sunk in the river to complete the retting process; but this double steeping is not invariably practised. When finally taken out, it is unloosed and put up in cones, instead of being grassed, and when quite dry it is stored for some time previous to undergoing the operation of scutching. In all operations the greatest care is taken, and the cultivators being peculiarly favored as to soil, climate, and water, Courtrai flax is a staple of unapproached excellence.

An experiment made by Professor Hodges of Belfast on 7770 ℔ of air-dried flax yielded the following results:—By rippling he separated 1946 ℔ of bolls which yielded 910 ℔ of seed. The 5824 ℔ (52 cwt.) of flax straw remaining lost in steeping 13 cwt., leaving 39 cwt. of retted stalks, and from that 6 cwt. 1 qr. 2 ℔ (702 ℔) of finished flax was procured. Thus the weight of the fibre was equal to about 9 per cent. of the dried flax with the bolls, 12 per cent. of the bolled straw, and over 16 per cent. of the retted straw. One hundred tons treated by Schenck's method gave 33 tons bolls, with 27·50 tons of loss in steeping; 32·13 tons were separated in scutching, leaving 5·90 tons of finished fibre, with 1·47 tons of tow and pluckings. The following analysis of two varieties of heckled Belgian flax is by Dr. Hugo Müller (Hoffmann's *Berichte über die Entwickelung der chemischen Industrie*):—

Ash	0·70	1·32
Water	8·65	10·70
Extractive matter	3·65	6·02
Fat and wax	2·39	2·37
Cellulose	82·57	71.50
Intercellular substance and pectose bodies	2·74	9·41

According to the determinations of Wiesner (*Die Rohstoffe des Pflanzenreiches*), the fibre ranges in length from 20 to 140 centimetres, the length of the individual cells being from 2·0 to 4·0 millimetres, and the limits of breadth between 0·012 and 0·025 mm., the average being 0·016 mm.

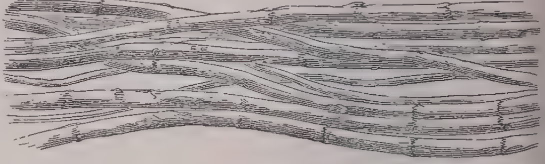

FIG. 2.—Fibre of Rough Russian Flax (magnified).

Among the circumstances which have retarded improvement both in the growing and preparing of flax, the fact that, till comparatively recent times, the whole industry was conducted only on a domestic scale has had much influence. At no very remote date it was the practice in Scotland for every small farmer and cotter not only to grow "lint" or flax in small patches, but to have it retted, scutched, cleaned, spun, woven, bleached, and finished entirely within the limits of his own premises, and all by members or dependants of the family. The same practice obtained and still largely prevails in other countries. Thus the flax industry was long kept away from the most powerful motives to apply to it labor-saving devices, and apart from the influence of scientific inquiry for the improvement of methods and processes. As cotton came to the front, just at the time when machine-spinning and power-loom weaving were being introduced, the result was that in many localities where flax crops had been grown for ages, the culture gradually drooped and ultimately ceased. The linen manufacture by degrees ceased to be a domestic industry, and began to centre in and become the characteristic factory employment of special localities, which depended, however, for their supply of raw material primarily on the operations of small growers, working, for the most part, on the poorer districts of remote, thinly populated countries. The cultivation of the plant and the preparation of the fibre have therefore, even at the present day, not come under the influence (except in certain favored localities) of scientific knowledge and experience, and the greater part of the flax in use at the present moment is prepared precisely by the processes employed in Egypt when the descendants of Jacob dwelt in the land of Goshen.

In England and Scotland the acreage under flax is now so limited, and it has decreased with such steadiness and rapidity, that, as a crop, flax may be regarded as practically extinct in these countries. Indeed, notwithstanding the numerous measures by which Government sought during last century to foster flax cultivation, and the direct grants to cultivators in Scotland, which down to the year 1828 were paid by the board of trustees for fisheries and manufactures, the cultivation cannot be said ever to have thriven in a healthy manner. The following summary, showing the extent in acres of the cultivation in Great Britain for the years 1870 till 1877 inclusive, has been communicated by Mr. Michael Andrews of Belfast:—

Year.	England.	Wales.	Scotland.	Total.
1870	22,354	204	1399	23,957
1871	15,949	175	1244	17,368
1872	14,011	84	1262	15,357
1873	13,752	190	741	14,684
1874	9,018	117	259	9,394
1875	6,547	54	150	6,751
1876	7,366	36	239	7,641
1877	7,210	28	243	7,481

In Ireland the cultivation of flax has always occupied a relatively much more important position than it has in the sister countries, though there also the experience is that it is a rapidly declining agricultural crop. In the time of Queen Anne a board of trustees of the linen and hempen manufactures for Ireland was instituted, by which body liberal grants were administered. The board continued its operations till the parliamentary grants were withdrawn in 1827, and itself dissolved in the following year. In 1841 a Royal Flax Society of Ireland was formed, which received from Government an annual subsidy of £1000, and it continued to exist till 1859. Still more recently a joint flax committee of the Royal Dublin Society and the Royal Agricultural Society of Ireland was formed, and administered grants from the imperial exchequer from the year 1864 till 1871. The acreage of Irish flax cultivated has fluctuated with these subsidies, having reached a maximum of 181,909 acres in 1824, from which it steadily declined to 53,863 acres in 1848. In 1853, partly stimulated by high prices and scarcity owing to Russian complications, it again rose to 174,579 acres; and the cotton famine consequent on the civil war in America again greatly stimulated the cultivation for a few years from 1862 onwards. The following are periodical returns from the registrar-general's statements since 1853:—

Table showing gross produce of Flax, yield per acre, and acreage under crop in Ireland, from the year 1853 to 1877 inclusive, according to the Registrar-General's Returns.

Year.	Acreage under Flax.	Gross produce.	Yield per Acre.	
		Tons.	Stones.	Lbs.
1853	174,579	43,862	40	3
1854	150,972	35,606	37	10
1855	97,106	23,428	38	9
1856	106,826	18,791	28	2
1857	98,074	14,475	23	9
1858	91,646	17,583	30	9
1859	136,282	21,576	25	5
1860	128,595	23,760	29	8
1861	147,866	22,568	24	6
1862	150,070	24,258	26	3
1863	214,099	42,646	31	12
1864	301,693	64,506	34	
1865	251,534	39,561	25	
1866	263,507	40,991	24	12
1867	253,257	35,392	22	5
1868	206,446	24,987	19	5
1869	229,178	29,569	20	8
1870	194,893	30,771	25	10
1871	156,883	12,929	13	3
1872	122,003	17,089	22	6
1873	129,432	19,843	24	8
1874	106,886	18,037	27	0
1875	101,248	22,464	35	7
1876	132,938	27,181	32	10
1877	123,362	No official	return.	

The foregoing table, and also the statistics given below, have been extracted from the carefully compiled reports of Mr. Michael Andrews for the Irish Flax Supply Association. The following statement embodies the latest available returns regarding the acreage and produce of flax in all the countries where the plant is cultivated on account of its fibre:—

Area under Flax and Gross Produce of various Countries.

		Statute Acres.	Stones.		Tons.
Austria	178,397 Jochs	253,323	at 21·48	per acre	34,009
Belgium	57,045 Hectares	140,901	" 33·59	"	29,580
Denmark		17,686	" 20·00	"	2,211
Egypt	(estimated)	15,000	" 20·00	"	1,875
France	78,774 Hectares	194,571	" 34·84	"	42,368
Germany	214,835 "	530,642	" 22·50	"	74,621
Great Britain		7,481	" 28·50	"	1,333
Greece		957	" 20·00	"	119
Holland	19,444 Hectares	48,027	" 31·77	"	9,536
Hungary	14,017 Jochs	19,903	" 20·00	"	2,488
Ireland		123,362	" 28.74	"	22,159
Italy	81,386 Hectares	201,023	" 18·14	"	22,791
Russia		1,928,568	" 20·00	"	241,071
Sweden		37,500	" 20·00	"	4,688
		3,518,944			488,849

It thus appears that the breadth of lands under flax in Russia alone is little less than four-sevenths of the entire acreage devoted to the production of the fibre, and that it alone produces practically one-half of the total produce of the world. The large extent to which the British manufacturers are dependent on Russia is shown in the following table:—

Imports and Exports of Flax, dressed and undressed, and Tow or Codilla, to and from the United Kingdom.

The total value of the imports was £3,539,501 in 1876, and in 1877 it was £5,054,555, the increase in quantity being 57·6 per cent., and in value 42·8 per cent.

Messrs. George Armitstead & Co. of Dundee have courteously placed at our disposal their flax list for the week ended 14th May, 1878, which not only shows the sources and varieties of flax found in the British market, but also gives an idea of the relative value of the various staples.

For the substance of the remarks on the commerce which follow we have also to express obligation to that firm.

The names and letters attached to the various brands are thus explained, commencing with Riga flax:—

K means Crown flax.
HK " Light crown flax.
PK " Picked crown flax.
HPK " Light picked crown flax.
SPK " Superior picked crown flax.
ISPK " Light superior picked crown flax.

It will be observed that the "H" stands for "light" colored flaxes; but besides being bracked as above, any of the Riga crown flaxes which are of a "white" or "gray" color are laid aside and shipped from Riga as under (mostly, however, to France and Belgium), viz:—

GK or WK, Gray crown, or white crown.
GPK or WPK, Gray picked crown, or white picked crown.
GSPK or WSPK, Gray or white superior picked crown.

These are the principal marks of Riga crown sorts. Of other qualities shipped from Riga there are "*Hoffs*" flaxes (drawn from the Livonian district):—

HD means Hoffs Dreiband flax.
WHD " White Hoffs Dreiband flax.
PHD " Picked white Hoffs Dreiband flax.
WPHD " White picked Hoffs Dreiband flax.
FPHD " Fine picked Hoffs Dreiband flax.
WFPHD " White fine picked Hoffs Dreiband flax.
SFPHD " Superior fine picked Hoffs Dreiband flax.
WSFPHD " White superior fine picked Hoffs Drieband flax.

Of the lower qualities of Riga flax the following may be named:—

W, Wrack flax. PW, Picked wrack flax.
WPW, White picked wrack. GPW, Gray picked wrack flax.
D, Dreiband (Threeband). PD, Picked Dreiband flax.
LD, Livonian Dreiband. PLD, Picked Livonian Dreiband.
SD, Slanitz Dreiband. PSD, Picked Slanitz Dreiband.

The last-named (SD and PSD) are dew-retted qualities shipped from Riga either as Lithuanian Slanitz, Wellish Slanitz, or Wiasma Slanitz, showing from what district they come, as there are differences in the quality of the produce of each district. The lowest quality of Riga flax is marked DW, meaning Dreiband Wrack.

Another Russian port from which a large quantity of flax is imported is Pernau, where the marks in use are comparatively few. The leading marks are—

LOD, indicating Low Ordinary Dreiband (Threeband).
OD, " Ordinary Dreiband.
D, " Dreiband.
HD, " Light Dreiband.
R, " Risten.
G, " Cut.
M, " Marienburg.

Pernau flax is shipped as Livonian and Fellin sorts, the latter being the best. The lowest mark of Pernau flax is the LOD. In addition to the exports from Riga and Pernau, shipments of flax are made from Narva, Libau, Memel, and Revel; but, as compared with the two first-mentioned ports, the flax trade of the others is inconsiderable. The only remaining localities from which flax is extensively exported to Scotland are Archangel and St. Petersburg. From St. Petersburg both white and brown flax is sent, the former variety being water-retted, the latter dew-retted. All the flax of Archangel is dew-retted.

The Pscow, Louga, Staro, Russ, and Saletsky flaxes are steeped or white flax, whereas the Rjeff flax is dew-retted. There are many other kinds which come into the Dundee market from St. Petersburg, such as Melinki, Bejetsky, Ouglitch, Kostroma, Jaroslav, Vologda, Wiasma, etc., taking their names from the various districts, and all dew-retted flax. These Petersburg brown flaxes are bracked mostly in 1st, 2d, 3d, and 4th crown, also Zabrack, the lowest mark. Some Petersburg sorts leave out the 1st crown and 4th crown, but in the Archangel flaxes all these marks appear, and the Zabrack is divided into two sorts, 1st and 2d Zabrack.

The distinction between codilla and tow is that the former is the tow or broken and ravelled fibres produced in the scutching process, therefore often called scutching tow, while tow proper is the similar product separated in the subsequent operation of heckling the flax preparatory to spinning. See AGRICULTURE (vol. i. pp. 337, 338), BLEACHING, LINEN, and LINSEED OIL. (J. PA.)

FLAXMAN, JOHN (1755-1826), was the greatest sculptor, or, if that title may be disputed on account of certain technical shortcomings in his work, at any rate the greatest designer of sculpture, that England has produced; and as a representative of the Greek spirit in modern art his name stands among the foremost, not of England merely, but of the world.

He was born on the 6th of July, 1755. His name, John, was hereditary in the family, having been borne by his father after a forefather who, according to the family tradition, had fought on the side of parliament at Naseby, and afterwards settled as a carrier or farmer, or both, in Buckinghamshire. John Flaxman the elder carried on with repute the trade of a moulder and seller of plaster casts in New Street, Covent Garden, London. Our sculptor was the second son of his parents, and was born while they were temporarily living at York. Within six months of his birth they returned to London, and in his father's back shop he spent an ailing childhood, in the course of which his life was once at least despaired of. His figure was high-shouldered and weakly, with the head very large for the body. His father by and by removed to a more commodious house in the Strand, and, his first wife dying, married a second, who proved a thrifty housekeeper and gentle stepmother. Of regular schooling the boy must have had some, since he is reputed as having remembered in after life the tyranny of some pedagogue of his youth; but his principal education he picked up for himself at home. He early took delight in drawing and modelling from his father's stock-in-trade, and early endeavored to understand those counterfeits of classic art by the light of translations from classic literature. Customers of his father took a fancy to the child, and helped him with books, advice, and presently with commissions. The two special encouragers of his youth were the painter Romney, and a cultivated clergyman, Mr. Mathew, in whose house in Rathbone Place the young Flaxman used to meet the lettered society of those days, and, among associates of his own age, the artists Blake and Strothard. Before this he had begun to work with success in clay as well as in pencil. At eleven years old, and again at thirteen, he won prizes from the Society of Arts. At twelve he became a public exhibitor in the gallery of the Free Society of Artists, and at fifteen in that of the Royal Academy, then in the second year of its existence. In the same year, 1770, he entered as an Academy student, and won the silver medal. But all these successes were followed by a discomfiture. In the competition for the gold medal of the Academy, Flaxman, who had made quite sure of victory, was defeated, the prize being adjudged by the president, Sir Joshua Reynolds, to another competitor named Engleheart. But this reverse proved no discouragement, and the young Flaxman continued to ply his art diligently, both as a student in the schools and as an exhibitor in the galleries of the Academy, occasionally also attempting diversions into the sister art of painting. Before long he received a commission, from a friend of the Mathew family, for a statue of Alexander. But by heroic and ideal work of this class—and it was work of this class that he at first almost exclusively exhibited—he could of course make no regular livelihood. The means of such a livelihood, however, presented themselves in his twentieth year, when he first received employment from Josiah Wedgwood and his partner Bentley, as a modeller of classic and domestic friezes, plaques, ornamental vessels, and medallion portraits, in those varieties of "jasper" and "basalt" ware which earned in their day so prodigious a reputation for the manufacturers who had conceived and perfected the invention, and of which the examples, dispersed and disregarded during the first fifty years of this century, have now again returned into favor among the curious, and are disputed in sale-rooms at prices greater than they fetched in the first fever of the fashion. For twelve years, from his twentieth to his thirty-second (1775–1787), Flaxman subsisted chiefly by his work for the firm of Wedgwood. It may be urged, of the extreme refinements of figure outline and modelling which these manufacturers aimed at in their ware, that they were not the qualities best suited to such a material; or it may be regretted that the gifts of one of the greatest figure designers who ever lived should have been employed upon such a minor and half-mechanical art of household decoration; but the beauty of the product it would be idle to deny, or the value of the training which the sculptor by this practice acquired in the delicacies, the very utmost delicacies and severities, of modelling in low relief and on a minute scale. By 1780 Flaxman had begun to earn something in another, and, so to speak, a more legitimate branch of his profession. This was in the sculpture of monuments for the dead. Three of the earliest of such monuments by his hand are those of Chatterton in the church of St. Mary Redcliffe at Bristol, of Mrs. Morley in Gloucester Cathedral, and of a widow comforted by an angel, in the cathedral at Chichester. During the rest of Flaxman's career memorial bas-reliefs of the same class occupied a principal part of his industry; they are to be found scattered in many churches throughout the length and breadth of England, and in them all the finest qualities of his art are represented. The best are quite unsurpassable for pathos, for simplicity, for an instinct of composition as just, pure, and lovely as that of the Greeks themselves, and for the alliance with those harmonious lines and groupings of the ancients of that spirit of domestic tenderness and innocence which is the secret, and the holiest secret, of the modern soul.

In 1782, being twenty-seven years old, Flaxman was married to Anne Denman, and had in her the best of helpmates until almost his life's end. She was a woman of attainments in letters and to some extent in art, and the devoted companion of her husband's fortunes and of his travels. They set up house at first in Wardour Street, and lived an industrious life, spending their summer holidays once and again in the house of the hospitable poet Hayley, at Eartham in Sussex. After five years, in 1787, they found themselves with means enough to travel, and set out for Rome. Records more numerous and more consecutive of Flaxman's residence in Italy exist in the shape of drawings and studies than in the shape of correspondence. He soon ceased modelling himself for Wedgwood, but continued to direct the work of other modellers employed for the manufacture at Rome. He had intended to return after a stay of a little more than two years, but was detained by a commission for a marble group of a Fury of Athamas, a commission attended in the sequel with circumstances of infinite trouble and annoyance, from the notorious Comte-Évêque, Frederick Hervey, earl of Bristol and bishop of Derry. He did not, as things fell out, return until the summer of 1794, after an absence of seven years,—having in the mean time executed another ideal commission (a Cephalus and Aurora) for Mr. Hope, and having sent home models for several funeral monuments, including that of the poet Collins in Chichester Cathedral. But what gained for Flaxman in this interval an immense and European fame was not his work in sculpture proper, but those outline designs to the poets, in which he showed not only to what purpose he had made his own the principles of ancient design in vase-paintings and bas-reliefs, but also by what a natural affinity, better than all mere learning, he was bound to the ancients and belonged to them. The designs for the *Iliad* and *Odyssey* were commissioned by Mrs. Hare Naylor; those for Dante by Mr. Hope; those for Æschylus by Lady Spencer. During their homeward journey the Flaxmans travelled through central and northern Italy. On their return they took a house, which they never afterwards left, in Buckingham Street, Fitzroy Square. Immediately afterwards we find a sculptor exhibiting the model of a large monument in the round, that of Lord Mansfield, now in Westminster Abbey, and at the same time publishing a spirited protest against the scheme already entertained by the Directory, and carried out five years later by Napoleon, of equipping at Paris a vast central museum of art with the spoils of conquered Europe.

The record of Flaxman's life is henceforth an uneventful record of private affection and contentment, of happy and tenacious industry; with reward not brilliant, but sufficient; with repute not loud, but loudest in the mouths of those whose praise was best worth having—Canova, Schlegel, Fuseli; of quiet, beloved, modestly enthusiastic, and simply honorable life. He took for pupil a son of Hayley's, who presently afterwards sickened and died. In 1797 he was made an associate of the Royal Academy. Every year he exhibited work of one class or another: occasionally a public monument in the round, like those of Paoli or Captain Montague for Westminster Abbey, and of Nelson or Howe for St. Paul's; more constantly, memorials for churches, with symbolic Acts of Mercy or illustrations of Scripture texts, both commonly in low relief; and these pious labors he would vary from time to time with a classical piece like those of his earliest predilection. Soon after his election as associate, he published a scheme, half grandiose half childish, for a monument to be erected on Greenwich Hill, in the shape of a Britannia 200 feet high, in honor of the naval victories of his country. In 1800 he was elected full Academician. During the peace of Amiens he went to Paris to see the despoiled treasures now actually collected there, but bore himself according to the spirit of protest that was in him. The next event which makes any mark in his life is his appointment to a chair specially created for him by the Royal Academy—the chair of Sculpture: this took place in 1810. We have ample evidence of his thoroughness and judiciousness as a teacher in the Academy schools, and his professorial lectures have been often reprinted. With many excellent observations, and with one singular merit,—that of doing justice, as in those days justice was hardly ever done, to the sculpture of the mediæval schools,—these lectures lack point and felicity of expression, just as they are reported to have lacked fire in delivery, and are somewhat heavy reading. The most important works that occupied Flaxman in the years next following this appointment were the monument to Mrs. Baring in Micheldever church, the richest of all his monuments in relief; that to Lord Cornwallis, destined for India; and that to Sir John Moore, for Corunna; with a pastoral Apollo for Lord Egremont. At this time the antiquarian world was much occupied with the vexed question of the merits of the Elgin marbles, and Flaxman was one of those whose evidence before the parliamentary commission had most weight in favor of the purchase which was ultimately effected in 1816. In 1817 we find him returning to his old practice of classical outline illustrations, and producing the happiest of all his series in that kind, the designs to Hesiod, engraved by the friendly hand of Blake. Immediately afterwards he is much engaged designing for the goldsmiths—a testimonial cup in honor of John Kemble, and, following that, the great labor of the famous Shield of Achilles. Almost at the same time he undertakes a frieze of Peace, Liberty, and

Plenty, for the duke of Bedford's sculpture gallery at Woburn, and an heroic group of Michael overthrowing Satan, for Lord Egremont's house at Petworth.

In 1820 died Mrs. Flaxman, after a first warning from paralysis six years earlier. Her younger sister, Maria Denman, and the sculptor's own sister, Maria Flaxman, remained in his house, and his industry was scarcely at all relaxed. In 1822 he delivered at the Academy a lecture in memory of his old friend and generous fellow-craftsman, Canova, then lately dead; in 1823 he received from A. W. Von Schlegel a visit of which that writer has left us the record. From an illness occurring soon after this he recovered sufficiently to resume both work and exhibition, but on the 26th of December, 1826, he caught cold in church, and died three days later, in his seventy-second year. Among a few intimate associates he left a memory singularly dear; having been in companionship, although susceptible and obstinate when his religious creed—a devout Christianity with Swedenborgian admixtures—was crossed or slighted, yet in other things genial and sweet tempered beyond all men, full of modesty, full of playfulness and of a homely dignity withal, the truest friend, the kindest master, the purest and most blameless spirit.

Posterity will doubt whether it was the fault of Flaxman or of his age, which in England offered neither training nor much encouragement to a sculptor, that he is weakest when he is most ambitious, and then most inspired when he makes the least effort; but so it is. Not merely does he fail when he seeks to illustrate the intensity of Dante, or to rival the tumultuousness of Michelangelo—to be intense or tumultuous he was never made; but he fails, it may almost be said, in proportion as his work is elaborate and far carried, and succeeds in proportion as it is partial and suggestive. Of his completed ideal sculptures, the St. Michael at Petworth is by far the best, and is indeed admirably composed from all points of view; but it lacks fire and force, and it lacks the finer touches of the chisel; a little bas-relief like the diploma piece of the Apollo and Marpessa in the Royal Academy compares with it favorably. Again, of Flaxman's complicated monuments in the round—we speak of the three in Westminster Abbey and the four in St. Paul's—there is scarcely one which has not something heavy and infelicitous in the arrangement, and something empty and unsatisfactory in the surface execution. But when we come to his simple monuments in relief, in these we find usually an almost complete felicity. The truth is, that he did not thoroughly understand composition on the great scale and in the round; but he thoroughly understood relief, and found scope in it for all his unrivalled gifts of rhythmical design, and tender, grave, and penetrating feeling. Of pity and love he is a perfect master, and shows, as no one had ever shown before, how poignantly those passions can be expressed in the simplest conceivable combinations of human shapes and gestures. But if we would see even these the happiest of his conceptions at their best, we must study them, not in the finished monument, but rather in the casts from his studio sketches, of which so precious a collection is preserved in the Flaxman gallery at University College. And the same is true of his happiest efforts in the classical and poetical vein, like the well-known relief of Pandora conveyed to Earth by Mercury. Nay, going further back still among the rudiments and first conceptions of his art, we can realize the most essential charm of his genius in the study, not of his modelled work at all, but of his outlined and tinted sketches on paper. Of these, too, there is at University College a choice collection, and many others are dispersed in public and private cabinets. Every one knows the excellence of the engraved designs to Homer, Dante, Æschylus, and Hesiod, in all cases save when the designer aims at that which he cannot hit, the terrible or the grotesque. To know Flaxman at his best, it is necessary to be acquainted not only with the original studies for such designs as these, but still more with those almost innumerable studies from real life which he was continually producing with pen, tint, or pencil. These are the most delightful and suggestive *sculptor's notes*, so to speak, in existence; in them it was his habit to set down, with a perfect feeling and directness, the leading or expressive lines, and generally no more, of every group that struck his fancy. There are groups of Italy and London, groups of the parlor and the nursery, of the street, the garden, and the gutter; and of each group the artist knows how to seize at once the structural and the spiritual secret, expressing perfectly the value and suggestiveness, for his art of sculpture, of the contacts, intervals, interlacements, and balancings of the various figures in any given group, and not less perfectly the charm of the affections which link the figures together and harmonize their gestures.

The materials for the life of Flaxman are scattered in various biographical and other publications; the principal are the following:—An anonymous sketch in the *European Magazine* for 1823; an anonymous "Brief Memoir," prefixed to *Flaxman's Lectures*, ed. 1829, and reprinted in subsequent editions; the chapter in Allan Cunningham's *Lives of the Most Eminent British Painters*, etc., vol. iii.; notices in the *Life of Nollekens*, by John Thomas Smith; in the *Life of Josiah Wedgwood*, by Miss G. Meteyard, London, 1865; in the *Diaries and Reminiscences of H. Crabbe Robinson*, London, 1869, the latter an authority of great importance; in the *Lives* of Stothard, by Mrs. Bray, of Constable, by Leslie, of Watson, by Dr. Lonsdale, and of Blake, by Messrs. Gilchrist and Rossetti; a series of illustrated essays, principally on the monumental sculpture of Flaxman, in the *Art Journal* for 1867 and 1868, by Mr. G. F. Teniswood; *Essays in English Art*, by Frederick Wedmore; *The Drawings of Flaxman, in 32 plates, with Descriptions, and an Introductory Essay on the Life and Genius of Flaxman*, by Prof. Sidney Colvin, M.A., atlas fol., London, 1876. (S. C.)

FLEA, an Anglo-Saxon name, probably derived from "fleogan," to fly, typically applied to *Pulex irritans*, a blood-sucking insect-parasite of man and other mammals, remarkable for its powers of leaping, and unfortunately too well known, even in our own temperate climate. Its position in classification has long been somewhat undecided; a separate order was erected for it and its allies under the various names of *Suctoria*, *Siphonaptera*, *Rophoteira*, and *Aphaniptera*, by De Geer, Latreille, Clairville, and Kirby respectively; and it is included in the *Aptera* of Lamarck, MacLeay, and others, and in the *Rhyngota* of Fabricius. Various affinities have also been attributed to the group, which has been supposed to have relations with the *Hymenoptera*, *Hemiptera*, and *Anoplura*, and even with the *Coleoptera* (beetles). As regards the latter order, it is noteworthy that a recently discovered allied group, *Platypsyllidæ*, founded upon a parasite on the beaver (and considered as a separate order by Westwood, under the name *Achreioptera*), has been with considerable show of reason referred to the beetles by so sound an entomologist as Dr. Leconte. As regards the flea, however, it is now generally accepted that its true affinities are with the *Diptera* or two-winged flies, as suggested by Lamarck and Strauss Durckheim. In that order, it is by some held to occupy, as a family *Pulicidæ* (with the *Platypsyllidæ*), the position of a sub-order, at the end, under the name *Aphaniptera* (see DIPTERA, vol. vii. p. 223); but by others it is placed before the *Mycetophilidæ*, at the head of the tribe *Eucephala* of the Nematocerous section of the great division *Orthorhapha*. The community of parasitic habits with the *Hippoboscidæ* (forest-flies and sheep-ticks) is to a certain extent the reason for the former position; but the earlier transformations seem to indicate a stronger relationship with the *Eucephala*. The general characters have been given under DIPTERA; but the structure of the mouth of the perfect insect may be specified. The labrum is obsolete; the mandibles are represented by two flat and long processes, strengthened by a mid rib, and having very finely toothed edges, and uniting with the slender central lingua to form a puncturing lancet. When not in use, this is protected by the labial palpi, which form a sort of tube. The maxillæ are small leathery plates, and their palpi, which are four-jointed and large, have been mistaken for antennæ. The power of leaping, as well known, is very great; but there is no apparent development of the hind femora to account for it (as in many jumping beetles), although the posterior legs are saltatorial. The great muscular power of fleas has been long turned to account by public exhibitors in all countries, who have under the pretence of taming or educating these minute creatures, made use of various contrivances to render the natural efforts of the insect to escape assume the appearance of trained action. An account of the methods employed will be found in the *American Naturalist*, vol. xi. p. 7, from the pen of Mr. W. H. Dall. In some cases the steady carriage of the flea is to be traced to fracture of its jumping legs. The female flea lays a few oblong white eggs, in dirty places on floors frequented by domestic animals. The larvæ, before hatching, have a frontal point, used in breaking the shell of the egg. They are long and worm-like, without feet, but with two small hooks at the tail, and short antennæ and mouth organs at the head. They are very active, and apparently feed upon animal substances, forming, when full grown, a silky cocoon. Many species are known, parasitic upon various animals and birds. They have been recorded as infesting the inside of rabbits' ears, and the neck of a fowl, from hedgehog, marmot, cat, dog, bat, squirrel, dormouse, ferret, weasel, hare, rabbit, rat, mouse, field-mouse, shrew, moor-hen, jackdaw, thrush, missel-thrush, blackbird, jay, bullfinch, chaffinch, yellow-hammer, pipit, blackcap, whitethroat, skylark, willow wren, long-tailed titmouse, siskin, stock-dove, wood-pigeon, common pigeon, starling, swallow, etc. (though it is by no means certain that these are all necessarily of distinct specific value); and a species has been described from the common fowl in Ceylon. A large species is often found in sandy pits, near the openings of the nests of sand-martins, and a very large one sometimes occurs in wet and marshy places, probably living upon the mole. For the latter parasite, and others in which the antennæ exhibit certain supposed peculiarities, a separate genus, *Ceratopsyllus*, has been proposed. In another flea, also found on the mole, no trace of eyes could be found, even under a high power. A very large species has been found on the Australian porcupine in Tasmania; and Kirby, in the *Fauna Boreali-Americana*, described as *Pulex gigas* a flea two lines long, which he believed to be the largest known. This was taken in 65° N. lat. Westwood has recorded 17 British species; and oddly enough the same number are noted from the Netherlands by Ritsema. Any notice of these parasites would be incomplete without a reference to the "jigger," "chigoe," "bicho de pé," "nigua," or "earth-flea,"—*Dermatophilus*, *Sarcopsyllus*, or *Rhynchoprion penetrans*, so well known as a burrower into the naked feet of men, in sandy localities in the West Indies and South America. So great is this pest, that serious trouble has been occasioned by it even to military expeditions in South America; and the French army in Mexico was much troubled by it. The entry is effected usually under the nail, by the impregnated female, which thereupon becomes enormously distended with an immense number of eggs. Inflammation and ulceration follow this attack, and unless great care is taken in extracting the insect, serious illness and even death result. A good plate of the metamorphoses of this species is given in the volume of the *American Naturalist* above quoted, p. 754. For an account of the medical aspects, see Dr. Laboulbène's article on the "Chique," in the *Dictionnaire Enclycopédique des Sciences Médicales* (Paris 1875), p. 239; and for an exhaustive history, Guyon's memoir in the *Revue et Magasin de Zoologie* for 1868 and 1869. Much attention does not appear as yet to have been paid to the *Pulicidæ* by naturalists, except as regards the anatomy of the common species. Dugès's "Recherches sur les Caractères Zoologiques du genre Pulex," in the *Annales des Sciences Naturelles*, vol. xxvii. (1832) p. 145, and J. Künckel's observations in the *Annales de la Société Entomologique de France*, 5^{e} sér. iii. p. 129, and as regards *P. irritans*, W. H. Furlonge's descriptions in the journal of the *Quekett Microscopical Club*, 1871, p. 189, and 1873, p. 12, and C. Ritsema's in the *Album der Natuur*, xi. (1872), p. 65, may be specially noticed. The name "flea" is frequently erroneously applied to many jumping or lively insects not allied to the *Pulicidæ;* for instance, the "turnip-flea" is a small beetle, *Phyllotreta undulata*, one of the *Halticidæ*. (E. C. R.)

FLÉCHIER, Esprit (1632–1710), bishop of Nismes, a respectable author, and one of the most celebrated preachers of his age, was born at Pernes, department of Vaucluse, on the 10th of June, 1632, and educated at Tarascon sur Rhône, in the College of the Fathers of the Congregation of Christian doctrine, of which his uncle, Hercule Audifret, also famous in his time for his talents as a preacher, was general. After having gone through the ordinary course of studies, Fléchier entered the Congregation, and, according to the constitution of the order, was immediately employed in teaching. In 1659, he became a professor of rhetoric at Narbonne, and there pronounced the funeral oration of M. de Rebé, archbishop of that city. A few months afterwards, the death of his uncle called him to Paris, where he laid aside the habit of the doctrinaire, and at first followed the humble occupation of a parochial catechist. He soon made himself known by his poetical compositions in Latin and French. In 1660, he addressed to Cardinal Mazarin a poem called *Carmen Eucharisticum*, celebrating the Peace of the Pyrenees; the following year he sang the birth of the dauphin in another poem (*Genethliacon*); but what first made him famous was a description in Latin verse of a brilliant tournament (*carrousel*), *Circus Regius*, given by Louis XIV. in 1662. Chapelain, the most influential critic of that time, brought his name under the notice of Colbert, with the remark, "Fléchier est encore un très bon poëte latin." He was now entrusted with the education of Louis Urbain Lefevre de Caumartin, afterwards *intendant* of finances and counsellor of state; and as the house of his pupil's father was then frequented by the most important personages both of the court and the city, Fléchier was introduced into the best society, and soon made many friends. He had to accompany Caumartin and his family to Clermont, where the king had ordered the *Grands Jours* to be held (1665), and where Caumartin was sent as keeper of the seals and representative of the sovereign. There he wrote his curious *Mémoires sur les Grand Jours d' Auvergne*, first published in 1844 by Gonod, in which he relates, in a half-romantic, half-historical form, the proceedings of this extraordinary court of justice. The duke of Montausier, who had become his patron, now procured for him the situation of *lecteur* to the dauphin. The sermons of Fléchier increased his reputation, which was afterwards raised to the highest pitch by his funeral orations. Having been chosen to pronounce that of Madame de Montausier (1672), he displayed so great ability on the occasion that in the following year he was made a member of the French Academy, along with Racine. The funeral oration of the Duchesse d'Aiguillon (1675), and, above all, that of Turenne (1676), are, with that of Madame de Montausier, his masterpieces in that branch of literature. The favors of the court now poured in upon Fléchier. The king gave him successively the abbacy of St. Leverin, in the diocese of Poitiers, the office of almoner to the dauphiness, and in 1685 the bishopric of Lavaur, from which he was in 1687 promoted to that of Nismes. Here Fléchier had occasion for the daily exercise of his great qualities, gentleness and moderation. The edict of Nantes had been repealed two years before; but the Calvinists were still very numerous at Nismes, and the sincerity of the conversion of such as had made abjuration was at best but doubtful. Fléchier, by his prudent conduct, in which zeal was tempered with charity, succeeded in bringing over some of them to his views, and made himself esteemed and beloved even by those who declined to change their faith. During the troubles in the Cévennes, he softened to the utmost of his power the rigor of the edicts, and showed himself so sensible of the evils of persecution, and so indulgent even to what he regarded as error, that his memory was long held in veneration amongst the Protestants of that district. In the famine which succeeded the winter of 1709, he did much to alleviate the prevalent distress, by assisting the poor in his diocese without regard to their religious tenets, declaring that all alike were his children. He died at Montpellier on the 16th February, 1710, at the advanced age of seventy-eight. Pulpit eloquence is the branch of belles lettres in which Fléchier excelled. He is indeed far below Bossuet, whose robust and sublime genius had no rival in that age; he does not equal Bourdaloue in earnestness of thought and vigor of expression; nor can he rival the philosophical depth or the insinuating and impressive eloquence of Massillon. But he is always ingenious, often witty, and nobody has carried further than he the harmony of diction,—a quality which is sometimes marred, it must be confessed, by an affectation of symmetry and a love of antithesis at variance with the principles of good taste. His two historical works, the histories of Theodosius and of Ximenes, are more remarkable for elegance of style than for the accuracy and comprehensive insight which are the chief requisites of a historian.

The following is a list of Fléchier's works, in the order of publication:—1. *La Vie du Cardinal Commendon*, Paris, 1671, 4to (also published in Latin, 1699, 12mo); 2. *Histoire de Théodose-le-Grand*, Paris, 1679, 4to; 3. *De Casibus Virorum Illustrium autore Antonio Maria Gratiano, opera et studio Sp. Flecherii*, Paris, 1680, 4to; 4. *Oraisons funèbres*, Paris, 1681, 4to and 12mo; 5. *Panégyriques des Saints*, Paris, 1690, 4to; 6. *Histoire du Cardinal Ximenes*, Paris, 1694, 4to; 7. *Sermons de morale prêchés devant le Roi, avec des Discours synodaux et les Sermons prêchés par Fléchier aux États de Languedoc et dans* *sa Cathédrale*, 3 vols, 12mo; 8. *Œuvres posthumes, contenant ses Harangues, Compliments, Discours, Poésies Latines, Poésies françaises*, Paris, 1712, 12mo; 9. *Mandements et Lettres pastorales*, Paris, 1712, 12mo; 10. *Lettres choisies sur divers sujets*, Paris, 1715, 2 vols. 12mo. The most complete collection of his works is that of the Abbé Ducreux, canon of Auxerre, Nismes, 1782, 10 vols. 8vo. Another edition, with a notice of his life by A. V. Fabre of Narbonne, Paris, 1825–28, 10 vols. 8vo, is very defective. His *Mémoires sur les Grands Jours d'Auvergne* were published in 1844 (2d edit., with a notice by Sainte-Beuve and an appendix by M. Chéruel, Paris, 1862). A MS. in the French National Library (Suppl. fr., No. 1016, fol.) contains a few compositions by Fléchier, both in prose and in verse, which are as yet unpublished. For Fléchier's biography, see L. Juillard du Jarry, *Oraison funèbre d'E. Fléchier, évêque de Nîmes*, Paris, 1710, 4to; Ch. F. Trinquelague, *Éloge d'E. Fléchier, évêque de Nîmes*, Nismes and Paris, 1777, 8vo.

FLECKNOE, Richard, a poet and dramatic writer in the reign of Charles II. He was an Irishman by birth, and was originally a priest of the order of Jesus. Like many of the small wits and minor poets of that day, Flecknoe owes the rescue of his name from oblivion to the satirical genius of Dryden. That satirist availed himself of Flecknoe's name as a stalking horse from behind which to assail the poetaster Shadwell, who had been appointed to replace him in the laureateship. The opening lines of this satire may be quoted as a specimen of the whole:—

> "All human things are subject to decay;
> And when fate summons, monarchs must obey.
> This Flecknoe found, who, like Augustus, young
> Was called to empire and had governed long;
> In prose and verse was owned without dispute
> Throughout the realms of nonsense absolute."

It is but fair, however, to remark, that clever and effective as this poem is, it is in its application to Flecknoe utterly unjust. Flecknoe was the author of several plays, only one of which, *Love's Dominion*, printed in 1654, was acted. This piece was republished in 1674, as *Love's Kingdom, a Pastoral Trage-Comedy.* This was not the play as acted, but as re-written and corrected. His minor pieces, though possessing no great merit in the matter of versification, nevertheless contain many happy turns of thought and felicities of expression. His *Damoiselles à la Mode*, printed in 1677, and addressed to the duke and duchess of Newcastle, and *Sir W. Davenant's Voyage to the Other World*, are a witty exposure of the literary and dramatic foibles of the day. The characters of the first named, he says in his preface, are "like so many precious stones I have brought out of France, and as a lapidary set in one jewel to adorn our English stage." They are adaptations from Molière. His unpopularity among the players, and the satire of Dryden, upon whom, nevertheless, Flecknoe composed a witty and graceful epigram, must have been in a great measure owing to his attacks on the immorality and general worthlessness of the English stage. An interesting but almost unknown production of Flecknoe's is *The Idea of His Highness Oliver late Lord Protector*, etc., London, 1659,—an appreciative estimate of Cromwell's character, as evidenced in his parliamentary career and his achievements as soldier and statesman. Flecknoe died in 1678.

His principal remaining works are—*Ermina; or, The Chaste Lady; The Marriage of Oceanus and Britannia; Epigrams and Enigmatical Characters*, 1670, in 8vo; *Miscellanea*, or poems of *all* sorts, with divers *other* pieces, 1653, in 12mo; *Diarium*, or the Journal, divided into twelve Jornadas, in burlesque verse, London, 1656, in 12mo. See also his *Discourse of the English Stage*, first published in the volume for 1869 of the Roxburgh Library, edited by Mr. W. C. Hazlitt.

FLEETWOOD, or Fleetwood-on-Wyre, a market-town, watering-place, and seaport of Lancashire, England, 22 miles by rail from Preston. It dates its rise from 1836, and takes its name from Sir P. H. Fleetwood, by whom it was laid out. The principal buildings are St. Peter's church, the Roman Catholic church, the Whitworth institute, and the Euston barracks, which have quarters for 300 men and 60 officers. The harbor is safe and extensive, and the shipping accommodation was increased in 1877 by the completion of a new dock, with an area of 10 acres and a maximum depth of 34 feet. Steamers ply regularly from Fleetwood to Belfast and the Isle of Man. The value of the imports in 1876 was £162,984 and of the exports of British produce £507. Population in 1871, 4428.

FLEETWOOD, Charles, lord-deputy of Ireland under the Commonwealth, and son-in-law of Cromwell, was born most probably in 1620. Entering the ranks of the parliamentary forces, he rose in 1644 to the rank of colonel of horse, and in 1645 was appointed governor of Bristol. At the battle of Dunbar in 1650 he was lieutenant-general of the horse; and at the battle of Worcester in 1651, the division commanded by him contributed chiefly to the victory of the parliamentary army. After the death of his first wife he was married to Bridget, eldest daughter of Cromwell and widow of Ireton; and in the same year he was appointed commander-in-chief of the forces in Ireland. In 1654 he became lord-deputy, but manifested such weakness and irresolution in dealing with the different political parties of Ireland that Cromwell in 1655 found it necessary to recall him. He was honored shortly afterwards, however, by being nominated one of the fourteen major-generals to whom the internal administration of the Commonwealth was entrusted. On the death of the Lord Protector he made an attempt, by means of his influence with the troops, to supplant Richard Cromwell: but he wanted sufficient ability and energy to carry out his purpose, and in the midst of his intrigues the nation recalled the exiled Stuarts. Fleetwood's prominent position marked him out as an object of vengeance to the restored king, and it was only with very great difficulty that he escaped with his life. Not long after the Restoration he died in wretchedness and obscurity at Stoke Newington, whither he had retired. That defect in his character which helped to ruin both him and the Protectorate did not escape the shrewd observation of Cromwell, who, in a letter written shortly after Fleetwood's marriage to Bridget Cromwell, gives him the exhortation, "Take heed of your natural inclination to compliance."

FLEETWOOD, William (1656–1723), a learned English bishop, was descended of an ancient family in Lancashire, and was born in the Tower of London, January 21, 1656. He received his education at Eton and at King's College, Cambridge. About the time of the Revolution he entered into holy orders, and was shortly afterwards made rector of St. Austin's, London, and lecturer of St. Dunstan's in the West. He became canon of Windsor in 1702, and in 1706 he was nominated to the see of St. Asaph, from which he was translated in 1714 to that of Ely. He died at Tottenham, Middlesex, on the 4th August, 1723. Bishop Fleetwood was regarded as the best preacher of his time, and his character stood deservedly high in general estimation. In liberal and enlightened piety he was considerably in advance of his age.

His principal writings are—*Essay on Miracles*, 1701; *Chronicum Preciosum*, 1707; and *Free Sermons*, 1712, containing sermons on the death of Queen Mary, the duke of Gloucester, and King William. A collected edition of his works was published in 1737.

FLEMING, Paul (1609–1640), a German poet, was born at Hartenstein, a village in Saxony, on October 5, 1609. His father, a clergyman, was transferred while Paul was still a child to a higher post at Wechselburg; and here, on the charming banks of the Mulda, Fleming grew to boyhood, being treated with great affection by a kind and intelligent stepmother. From about the age of fourteen he attended school in Leipsic, and five or six years later he became a student at the university of that town. He was a youth of manly and generous character, and soon gave evidence of poetical talent in the occasional verses he was already fond of writing. He had many friends among his fellow-students, and keenly enjoyed his life in Leipsic; but in 1633 he was driven away by the horrors of the Thirty Years' War. It happened that about this time the duke of Holstein had resolved to send an embassy to Persia, with the view of opening for his subjects new channels of trade. Through Olearius, who was made secretary of the embassy, and afterwards wrote an interesting account of its proceedings, the young poet heard of the duke's purpose. Fired by the prospect of foreign travel, and with a vague idea that great results might be achieved by bringing East and West into closer contact, he went to Holstein and offered the duke his services. The offer was accepted; and when, a few months later, the embassy started, Fleming accompanied it as a subordinate official. Difficulties arose at Moscow, and the chiefs of the expedition returned to Holstein for instructions, leaving the inferior members, among them Fleming, at Revel. Here they were detained for more than a year, but he had no reason to regret the fact, since there were in Revel many cultivated German families who received him with pleasure. In the spring of 1636 the embassy set off anew, and it was absent rather more than three years, reaching Ispahan in 1637, and passing through many stirring adventures on the way. The pleasure of the enterprise was marred by the tyrannical disposition of one of the leaders; but if we may judge from the buoyant tone of the poems written during the journey, Fleming must have had many happy hours amid the strange scenes he visited. In April, 1639 he found himself once more in Revel, and as a lady who had promised to become his wife had married during his absence, he now wooed a certain Fräulein Anna, who had been too young during his former visit to attract his notice. At Leipsic he had attended lectures in medicine, and after his betrothal it occurred to him to settle in Revel as a physician. He went to Leyden, and obtained a diploma; but the fatigues of travel had helped to undermine his constitution, and on his way back to Revel he died at Hamburg, April 2, 1640, when little more than thirty years of age.

His fame was not very great in his own day; but it has steadily increased ever since, and he is now universally admitted to have been the most brilliant German poet of the 17th century. After the Reformation, poetry almost died out in Germany; it could not make itself heard amid the noise of contending theological sects. Martin Opitz, the founder of the so-called First Silesian school, heralded the approach of a new literary epoch. Fleming began his career as a disciple of this author, whose methods of versification he adopted; and without being aware of it he speedily rose far above his master. The younger poet had genius, of which there is no trace in the correct but tedious compositions of Opitz. Some of the rudeness of his age still clung to Fleming; but his feeling is always intense, and he often gives it voice in lines of exquisite melody. Although he does not seem to have searched laboriously for appropriate epithets, he is justly famous for the wealth, aptness, and beauty of his phraseology. His genius was purely lyrical, and he never sought to pass beyond the limits which nature had imposed upon him. Within these limits, however, the range of his *Geist und Weltliche Poëmata* is unusually wide. In his religious poetry—notably in the well-known hymn beginning "In allen meinen Thaten"—the sorrows of a generation tormented by a fearful war found pathetic utterance; but this did not hinder him from writing some of the gayest and most alluring love verses in the German language. His sonnets breathe a spirit of lofty independence, betokening a mind which has grappled seriously with the hardest problems of life, but which has lost none of the confidence, ardor, and charm of youth.

Fleming's writings were admirably edited by the late T. M. Lappenberg. As, however, a large number of them relate to special events, and the poet did not always succeed in giving these events an ideal interest, most readers will be satisfied with the ample selection from his works in the second volume of the series entitled *Deutsche Dichter des siebzehnten Jahrhunderts*, edited by K. Gödeke and J. Tittman (Leipsic, 1870). A valuable study of the poet will be found in Varnhagen von Ense's *Biographischen Denkmalen*, bd. iv. (Berlin, 1826).

FLEMISH LITERATURE. See Holland.

FLEMMING, or Flemmynge, Richard (died 1431), bishop of Lincoln, and founder of Lincoln College, Oxford, was born at Crofton in Yorkshire. He was descended from a good family, and was educated at University College, Oxford. Having taken his degrees, he was made prebendary of York in 1406, and the next year was one of the proctors of the university. At this period of his life he embraced the doctrines of Wickliffe, and by his earnest advocacy won over many persons, some of high rank, to the side of the Reformer. But by some means a change was wrought in him, and he not only ceased to speak against the corruptions of the Roman system, but became one of Wickliffe's most determined opponents. Before 1415 he was instituted to the rectory of Boston in Lincolnshire, and in 1420 he was consecrated bishop of Lincoln. In 1424 he attended the council of Siena, a continuation of the council of Constance, and in the presence of the pope, Martin V., made an eloquent speech in vindication of his native country. It was probably on this occasion that he was named chamberlain to the pope. To Bishop Flemming was intrusted the execution of the decree of the council for the exhumation and burning of Wickliffe's remains. The see of York being vacant, the pope conferred it on Flemming; but in consequence of the vehement opposition of Henry V. to the project, it was given up, and Flemming remained bishop of Lincoln. In 1427 he obtained the royal license empowering him to found a college at Oxford for the special purpose of training up disputants against Wickliffe's heresy. While the work was in progress the founder died at his palace at Sleaford, January 26, 1431. Lincoln College was, however, completed by his trustees, and its endowments were afterwards augmented by various benefactors.

FLENSBURG, or Flensborg, the capital of a circle in the government district of Schleswig-Holstein, Prussia, is situated at the head of the Flensburg Ford, 20 miles north by west of Schleswig. It is the most important commercial town in what was formerly the duchy of Schleswig, and possesses several wharfs, a large shipbuilding yard, breweries, distilleries, foundries, oil-mills, sailcloth and paper manufactories, glass-works, copper-works, soap-works, and rice-mills. It has a number of vessels engaged in the West India trade, and in the Greenland whale fishery; and it also carries on a considerable oyster trade. The principal public buildings are the market houses, the exchange, the theatre, the real school, the agricultural school, and the hospital. The cemetery is interesting as containing the remains of the Danish soldiers who fell in the battle of Idstedt (25th July, 1850). A marble headstone has been placed at each grave—officers and common soldiers—with the same simple inscription on each, after the name and rank, "Fell at Idstedt." The colossal Lion monument, erected by the Danes to commemorate the victory of Idstedt, was removed to Berlin in 1864. Flensburg was founded in the 12th century, and received the privileges of a town from King Waldemar in 1284. The population in 1875 was 26,525.

FLETCHER, Andrew (1653–1716), of Saltoun, a prominent figure in Scotch history during the latter half of the 17th century, was born in 1653 at his ancestral home in East Lothian, and for five years was taught by the celebrated Gilbert Burnet, who was then minister of the parish of Saltoun. On reaching manhood he visited the Continent, where he spent several years in travel and study. In 1681 he was returned as commissioner for his native county to the Scottish parliament, where he distinguished himself by such determined opposition to the arbitrary measures of the court that he was forced to seek refuge in Holland, while sentence of outlawry (with confiscation of his estates) was passed against him. Four years later he joined the expedition of the duke of Monmouth; but on their landing at Lyme in Dorsetshire, he had the misfortune to kill the mayor of the town in a quarrel, and was compelled once more to seek safety abroad. During the second period of exile he travelled in disguise through Spain, where he had some romantic adventures. He next made a tour through Hungary, where he fought as a volunteer in a Turkish campaign; and finally at the Hague he took an active part in forwarding the scheme of the English Revolution. In 1688 he returned to Scotland when he at once regained his estates, and also sat as a member in the Scottish convention and afterwards in the parliament. An enemy of the monarchical form of government, he began to oppose the ministry of William almost as stoutly as he had resisted that of Charles; and that he exercised power in parliament is shown by the triumphant passing of the Act of Security of 1703, which, ripened under his care, contained two important constitutional laws restraining the power of the monarch of making war without the consent of parliament, and providing that all places and offices should be given by parliament. During the years of negotiations, as leader of the national party, he was consistent in his objections to the projected terms of the union of the crowns of England and Scotland, and supported his measure of limitations in animated speeches. After the Union he retired from public life; but in 1710 he did his country a real if homely service by introducing from Holland the art of making pot barley, and also the use of fanners for sifting grain. He died in London in 1716. A contemporary describes him as a "low, thin man, of a brown complexion; full of fire; with a stern, sour look.' Among the small band of good early Scotch prose authors he holds a prominent place, and in the domain of politics he is the most readable and entertaining of them all. His style has the singular freshness of foreign culture, and, charged with strong feeling, his sentences frequently turn into forcible epigrams. But both his writings and his speeches possess a value beyond that of literary excellence; they afford us bright glimpses of the manners and state of the country of his time. In literature his name is best known in connection with an often quoted remark, which occurs in *An Account of a Conversation concerning a right Regulation of Governments for the Common Good of Mankind:*—"I said I knew a very wise man so much of Sir Christopher's [Musgrave] sentiment, that he believed if a man were permitted to make all the ballads he need not care who should make the laws of a nation. And we find that most of the ancient legislators thought they could not well reform the manners of any city without the help of a lyric, and sometimes of a dramatic poet."

See *The Political Works of Andrew Fletcher, Esq.*, Glasgow, 1749, to which estimates of his character by Rawlinson and Lockhart are prefixed; *Essay on his Life and Writings*, by the Earl of Buchan, 1792; *Historical Account of the Ancient Rights and Power of the Parliament of Scotland*, 1823, a labored, interesting treatise, first published anonymously and now attributed to Fletcher.

FLETCHER, Giles (1548–1610), LL.D., father of the poets Giles and Phineas Fletcher, was himself a very distinguished man. He was born at Watford, in 1548; he studied at Cambridge, and after a stormy youth represented Winchelsea in parliament in 1585. In 1587 he travelled in Holland and Germany, and spent 1588–89 in Russia. In 1591 he printed his singular work, *The Russ Commonwealth*, which was suppressed for fear of angering the czar; in 1593 he brought out a volume of poems entitled *Licia*. He died in 1610.

FLETCHER, Giles (1584–1623), English poet of the 17th century, was born in London about 1584. He was the second son of Dr. Giles Fletcher, nephew of Richard Fletcher, bishop of London, cousin of John Fletcher the dramatist, and younger brother of Phineas Fletcher. He went very young to Cambridge, and as early as 1603 he contributed a poem on the death of Queen Elizabeth to a volume entitled *Sorrow's Joy*. He was a bachelor of divinity of Trinity College, and remained at the university until 1617 or later. In 1610 he published his great poem of *Christ's Victory and Triumph*, of which a second edition appeared in 1632. In 1612 he edited the *Remains* of his cousin Nathanial Pownoll. It is not known in what year he was ordained, but he became a famous preacher from the pulpit of St. Mary's, and was popular for the florid religious rhetoric then in vogue. He left Cambridge to accept, it is supposed from the hand of Lord Bacon, the rectory of Alderton, on the coast of Suffolk, where "his clownish and low-parted parishioners valued not their pastor according to his worth, which disposed him to melancholy and hastened his dissolution." In 1623 he published *The Reward of the Faithful*, a theological treatise in prose, and died in the same year, leaving a widow. The principal work by which Giles Fletcher is known is one of the most remarkable religious poems in the language. Its full title is *Christ's Victory and Triumph, in Heaven, in Earth, over and after Death.* It is in four cantos, divided according to the suggestion of the title; the metre is an eight-line stanza adapted from the Spenserian by the omission of the seventh line. Giles Fletcher, like his brother Phineas, was a disciple of Spenser, whom he follows with more vigor and brilliance than any poet of his time. His style has much more nervous strength, terseness, and melody than his brother's, and he had his subject far more thoroughly under control. In his very best passages Giles Fletcher attains to a rare sublimity, and to a rich voluptuous music which charmed the ear of Milton. It was his misfortune to live in an age which considered the poems of Marini and Gongora insuperable, and he strives too often to outdo these his patterns in grotesque conceit. But when he is carried away by his theme, and forgets to be ingenious, he attains an extraordinary solemnity and harmony of style. His description of the Lady of Vain Delight, in the second canto, has been greatly admired; the portrait of Justice is even nobler still, and of the first order of poetry. Milton did not hesitate to borrow very considerably from the *Christ's Victory and Triumph* in his *Paradise Regained.* Fletcher died in 1623.

The poetical writings of the Giles Fletchers, father and son, have been edited by Dr. A. B. Grosart, who has succeeded in clearing up a great deal of the obscurity that till lately lay around their careers. The *Russ Commonwealth* has been reprinted and edited by Mr. Bond. The prose works of Giles Fletcher the younger have never been reprinted.

FLETCHER, John (1579–1625). See Beaumont and Fletcher.

FLETCHER, Phineas (1582–c. 1665), English poet, and brother of Giles Fletcher the younger, was the eldest son of Dr. Giles Fletcher. He was born at Cranbrook, in Kent, in April, 1582. He was admitted a scholar of Eton, and in 1600 entered King's College, Cambridge. In 1603 he contributed verses to *Sorrow's Joy.* He was in priest's orders in 1611. In 1614 his pastoral drama of *Sicelides* was acted before the university. He left Cambridge to become chaplain to Sir Henry Willoughby in 1616; the same patron presented him in 1621 with the rectory of Hilgay in Norfolk; in the same year he married. He named his eldest son Edmund, in honor, no doubt, of Edmund Spenser, for whom he preserved an intense admiration. In 1627 he published his long poem, in Latin and English, of *Locustæ, or the Apollyonists*, a furious invective against the Jesuits. Next year appeared a fine but sensuous poem, entitled *Britain's Ida*, which was attributed on the title-page to Spenser; but many critics, and particularly Dr. A. B. Grosart, consider it to be the work of Phineas Fletcher. The drama of *Sicelides* was printed in 1631. In 1632 he brought out a theological treatise in prose, entitled *Joy in Tribulation*, and in 1633 his *magnum opus*, the famous poem of *The Purple Island.* His *Piscatory Eclogues* and *Miscellaneous Poems* appeared on the same occasion. It is believed that in 1650 he was ejected from his living, but nothing is known of the date or circumstances of his death. In the preface to his posthumous prose work, *A Father's Testament*, published in 1670, he is spoken of as having been some years dead. The *Purple Island, or the Isle of Man*, is a poem in twelve cantos, describing in cumbrous allegory the whole physiological and intellectual construction of the human body. The veins are spoken of as rivers, the bones as mountains, and the ingenuity as well as scientific knowledge displayed is very considerable. The manner of Spenser is preserved throughout, though not so closely as to destroy the distinct flavor of original genius. The allegory itself is found very tedious and prosaic at the present day; but some of the reflective passages, and the rich jewelled descriptions of Arcadian scenery possess living charm. Five cantos are occupied with the phenomena of the body, and seven with those of the mind. The *Piscatory Eclogues* have nothing to do with fishing; they are simply pastorals in the usual style, the characters being supposed to be fisher-boys reposing by the river Cam. The poetry of Phineas Fletcher never approaches the occasional sublimity of that of his brother Giles; it carries the Marini manner to a still more tasteless excess; but it is generally fluent, luxurious, and lacking neither color nor music.

A very complete edition of the poetical works of Phineas Fletcher, in 4 vols., was privately printed by Dr. Grosart in 1868. It is the only careful reprint that has been issued.

FLEURANGES, Robert (III.) de la Marck, Seigneur de (1491–1537), marshal of France, historian, was born of an ancient family at Sedan in 1491. A fondness for military exercises displayed itself in his earliest years, and at the age of ten he was sent to the court of Louis XII., and placed in charge of the count of Angoulême, afterwards King Francis I. In his twentieth year he married a niece of the Cardinal d'Amboise, but after three months he quitted his home to join the French army in the Milanese. With a handful of troops he threw himself into Verona, then besieged by the Venetians; but the siege was protracted, and being impatient for more active service, he rejoined the army. He then took part in the relief of Mirandola, besieged by the troops of Pope Julius II., and in other actions of the campaign. In 1512, the French being driven from Italy, Fleuranges was sent into Flanders to levy a body of 10,000 men, in command of which, under his father, he returned to Italy in 1513, seized Alexandria, and vigorously assailed Novara. But the French were defeated, and Fleuranges narrowly escaped with his life, having received more than forty wounds. He was rescued by his father and sent to Vercellæ, and thence to Lyons Returning to Italy with Francis I. in 1515, he distinguished himself in various affairs, and especially at Marignano, where he had a horse shot under him, and contributed so powerfully to the victory of the French that the king knighted him with his own hand. He next took Cremona, and was there called home by the news of his father's illness. In 1519 he was sent into Germany on the difficult errand of inducing the electors to give their votes in favor of Francis I.; but in this he failed. The war in Italy being rekindled, Fleuranges accompanied the king thither, fought at Pavia (1525), and was taken prisoner with his royal master. The emperor sent him into confinement in Flanders, where he remained for some years. During this imprisonment he was created marshal of France. He employed his enforced leisure in writing his *Histoire des choses mémorables advenues du règne de Louis XII. et de François I., depuis 1499 jusq' en l'an 1521.* In this work he designates himself *Jeune Adventureux.* Within a small compass he gives many curious and interesting details of the time, writing only of what he had seen, and in a very simple but vivid style. The book was first published in 1735, by Abbé Lambert, who added historical and critical notes; and it has been reprinted in several collections. The last occasion on which Fleuranges was engaged in active service was at the defence of Peronne, besieged by the count of Nassau in 1536. In the following year he heard of his father's death, and set out from Amboise for his estate of La Marck; but he was seized with illness at Longjumeau, and died there in December, 1537.

FLEUR-DE-LIS, an heraldic device. Concerning its origin the most diverse theories have been broached. According to an old tradition, it was first employed as an armorial bearing by Clovis I., and represents the lily presented by an angel to that monarch at his baptism, the three fleurs-de-lis of his shield being the sign of the Trinity. Newton (*Display*, p. 145) considers it to be the figure of a reed or flag in blossom, used instead of a sceptre at the proclamation of the Frankish kings. In the opinion of Chifflet, the device was first adopted by Louis VII. of France, surnamed le Jeune, in allusion to his name Louis Florus. Some, again, have held that it is the extremity of the *francisque*, a kind of javelin anciently used in France. An objection fatal to the above and other theories assigning to the fleur-de-lis a purely French origin is that it was early an ornament of the sceptres, seals, and robes, not only of the Merovingian, but of Greek, Roman, German, Spanish, and English kings, and was a symbol employed by many noble families in various parts of Europe in the 12th and 13th centuries. It is stated to occur, very perfectly sculptured, in the head-dresses of Egyptian sphinxes (*Notes and Queries*, 2d ser., i. p. 226). Gioja of Amalphi is said by Moreri to have marked the north end of the needle of the mariner's compass with a fleur-de-lis in honor of the king of Naples; but see Compass, vol. vi. pp. 200 and 202. Since the 12th century the fleur-de-lis, or "flower-de-luce" (Shakespeare), has been employed as the symbol of royalty in France.

See Heraldry; Berry, *Encyclopædia Heraldica*, vol. i., 1828; Boutell, *Heraldry*, 1865; and Larousse, *Dictionnaire Universel du XIX^{e} Siècle*, t. viii.

FLEURY, André Hercule de (1653–1743), cardinal, the celebrated minister of Louis XV. of France, was born in 1653 at Lodève, in Languedoc. He was educated by the Jesuits at Paris, and became successively almoner to Marie Thérèse, queen of Louis XIV., in 1698 bishop of Fréjus, and in 1715 preceptor to the young prince, who afterwards succeeded to the throne as Louis XV. On the death of the regent Orleans in 1723, Fleury advised his royal pupil to choose the duke of Bourbon as minister, and was himself made a member of the council. In 1726, being then in his seventy-third year, he received a cardinal's hat, and was called to the office of prime minister, which he held till his death in 1743. At the time when Fleury was entrusted with the direction of affairs, the condition of France was truly deplorable. The nation was impoverished and worn out, and the exchequer emptied by the long wars of the Grand Monarque and the extravagances of the regent. Commerce was annihilated, public credit ruined, the Government held in contempt, and the church distracted by internal dissensions. Fleury immediately set himself to the task, and effected important reforms. Though he was a confirmed friend to peaceful measures, he was twice driven by court intrigues to take part in foreign wars,—first in the case of Stanislaus Leczinsky, the dethroned king of Poland, whose daughter Louis XV. had married; and afterwards in that of the Austrian Succession, of which he did not live to see the end. In these wars, his economy, which bordered on avarice, was fatal to the cause espoused by France. The navy, neglected for fear of the expense, was no longer equal to any emergency. The Polish war he had energy neither to avert nor to carry on effectively. The meanly equipped expedition which he sent to the coasts of Pomerania could not but fail, notwithstanding the heroism displayed at Dantzic by the count of Plélo and his 1500 soldiers. One of the most useful acts of Fleury's administration was the completion of the Royal (now the National) Library, which he enriched with many valuable manuscripts, chiefly in the Oriental languages. He was a scholar of considerable attainments. The French Academy elected him as a member in 1717, the Academy of Sciences followed this example in 1721, and the Academy of the Inscriptions et Belles-Lettres in 1725. He was also provisor of Sorbonne, and superior of the college of Navarre.

FLEURY, Claude (1640–1723), the famous ecclesiastical historian, was born at Paris, December 6, 1640. Destined for the bar by his father, he was placed at the college of Clermont (now that of Louis-le-Grand), where the sons of the first families of France were educated. After passing brilliantly through the regular collegiate studies, he was nominated an advocate to the parliament of Paris in 1658, and continued during nine years to pursue the legal profession. Feeling a strong desire to enter the church, being fond of solitude, but especially influenced by the religious sentiments which he had imbibed during his early education, he renounced the law—which with history and literature, up to this time had formed the principal objects of his study—in order to devote himself to theology exclusively. He had already been some time in holy orders, when Louis XIV., in 1672, selected him as tutor of the princes of Conti; and so well did he acquit himself in this office, that the king intrusted to him afterwards the education of the count of Vermandois, one of his natural sons; and at the death of the young prince, Fleury received as recompense for his services the abbey of Loc-Dieu, in the diocese of Rhodez. Five years after this (1689) he was appointed sub-preceptor of the dukes of Burgundy, of Anjou, and of Berri. He thus became intimately associated with Fénelon, the chief preceptor of his royal pupils. In 1696 he was selected to fill the place of La Bruyère in the French Academy; and on the completion of the education of the young princes, the king bestowed upon him the rich priory of Argenteuil, in the diocese of Paris (1706). On assuming this benefice he resigned that of the abbey of Loc-Dieu, thus setting an example of rare disinterestedness. It was about this time that he decided, according to the suggestions of his friends, on commencing his great work, for which he had been collecting materials for thirty years—the *Histoire Ecclésiastique.* Hitherto France did not possess any work of equal merit in this department of literature. There existed many works more or less voluminous on matters of doctrine and discipline; but no one had written a history of the church,—a complete and scientific exposition of the progress of Christian society, of its organization and its primitive doctrine, of its varied changes in connection with the state, of the successive development of its institutions, of all the modifications introduced into its symbols and its rites. Fleury had evidently the intention of writing a history of the church for all classes of society; but at the time in which his great work appeared it was less religion than theology that absorbed the attention of the clergy and the educated public; and his work, as well as all those that had been published previously, is therefore more a work for the student than one for the people, dwelling as it does very particularly on questions of doctrine, of discipline, of supremacy, and of rivalry between the priesthood and the imperial power while it notices very slightly general questions affecting religion and morality. This fault, which was then looked upon as a merit, secured to the *Histoire Ecclésiastique* a very great success. The first edition, printed at Paris in 20 volumes 4to, 1691, was followed by many others, among which may be mentioned that of Brussels, in 32 vols. 8vo, 1692, and that of Nismes, in 25 vols. 8vo, 1778 to 1780. The work of Fleury only comes down to the year 1414. It was continued by J. Claude Fabre and Goujet down to 1595, in 16 vols. 4to. In consulting the work of Fleury and its supplement, the general table of contents, published by Rondel, Paris, 1758, 1 vol. 4to, will be found very useful. Translations have been made of the entire work into Latin, German, and Italian. The Latin translation, published at Augsburg, 1758-59, 85 vols. 8vo, carries the work down to 1684. Fleury, who had been appointed confessor to the king in 1716, died in 1723.

Fleury left many works besides his *Histoire Ecclésiastique*. The following deserve special mention :—*Histoire du Droit françois*, 1674, 12mo ; *Catéchisme historique*, 1679, 12mo ; *Mœurs des Israélites*, 1681, 12mo ; *Mœurs des Chrétiens*, 1682, 12mo ; *Traité du choix et de la méthode des études*, 1686, 2 vols. 12mo ; *Institution du Droit ecclésiastique*, 1687, 2 vols. 12mo ; *Les Devoirs des maîtres et des domestiques*, 1688, 12mo. The Roman Congregation of the Index has condemned the *Catéchisme historique* and the *Institution du Droit ecclésiastique*. The books to be specially consulted on Fleury's biography are—Chr. Ernst Simonetti, *Der Character eines Geschichtsschreibers in dem Leben und aus den Schriften des Abbts C. Fleury*, Göttingen, 1746, 4to ; J. F. Lebret, *Dissertatio de C. Fleuryo, Gallo-catholico au acatholico*, Tübingen, 1800, 4to; Chr. F. Ph. Jaeger, *Notice sur C. Fleury, considéré comme historien de l'Église*, Strasburg, 1847, 8vo.

FLIEDNER, THEODORE (1800-1864) a German philanthropist and restorer of the office of deaconess to the Protestant Church of Germany, was born January 21, 1800, at Eppstein, a small village on the frontiers of Hesse and Nassau, where his father was parish clergyman. He early showed a preference for the pastoral office, to qualify himself for which he studied at the universities of Giessen and Göttingen, and at the theological seminary of Herborn. At the age of twenty he passed his final examination ; and after a year spent in teaching and preaching, he accepted a call from the Evangelical Church at Kaiserswerth, a little town on the Rhine a few miles below Düsseldorf. His stipend was only £27, and the failure, soon after he was settled, of a large firm of velvet manufacturers, which supplied a large proportion of the members of his congregation, rendered even this small sum no longer secure. To provide an endowment for his church, he undertook journeys through part of Germany, and then to Holland and England. He met with considerable success, and had opportunities of observing what was being done in those countries towards prison reform, a subject which soon attracted his attention. The German prisons were then in a very bad state. The prisoners were huddled together in dirty rooms, were badly fed, and were left in complete idleness. No one dreamed of instructing them or of collecting statistics to form the basis of useful legislation on the subject. Fliedner at first singly undertook the work. He applied for permission to be imprisoned for some time, in order that he might look at prison life from the inside. This petition was refused, but he was allowed to hold fortnightly services in the Düsseldorf prison, and to visit the inmates individually. The work grew. Those interested in the subject banded themselves together, and on June 18, 1826, the first Prison Society of Germany was founded. The fact was clearly recognized that if any permanent good was to be done, the prisoners must be looked after on their release ; and therefore in 1833 Fliedner opened at Kaiserswerth a refuge for discharged female convicts. His circle of practical philanthropy rapidly increased. The state of the sick poor had for some time excited his interest, and it seemed to him that hospitals might be best served by an organized body of women specially trained and devoted to the work. Accordingly, in 1836 he began the first deaconess house, and the hospital at Kaiserswerth. By their ordination vows the deaconesses devoted themselves to the care of the poor, the sick, and the young. They were to be dressed in a plain uniform without distinctive badge, and their engagements were not final—they might leave their work and return to ordinary life if they chose. To these institutions Fliedner added in 1836 an infant school, then a normal school for infant school mistresses, an orphanage for orphan girls of the middle class (1842), and an asylum for female lunatics (1847). Besides these, he assisted at the foundation and in the management of various similar institutions not only in Germany, but in different parts of Europe.

In 1849 he resigned his pastoral charge, and from 1849 to 1851 he travelled over a large part of Europe, America, and the East,—the object of his journeys being to found "mother houses," which might not merely be training-schools for deaconesses, but also centres whence other training-establishments might arise. He established a deaconess house in Jerusalem, and after his return assisted by counsel and money in the erection of establishments at Constantinople, Smyrna, Alexandria, and Bucharest. Among his later efforts may be mentioned the Christian house of refuge for female servants in Berlin (connected with which other institutions soon arose) and the "house of evening rest" for retired deaconesses at Kaiserswerth. These and similar labors wore out a naturally strong constitution, and in 1856 he visited the East for the sake of his health. He returned worse rather than better, and thereafter was for the most part confined to his room ; he continued, however, by correspondence to promote the objects of his life. He died October 4, 1864, leaving behind him over 100 stations attended by 430 deaconesses ; and these by 1876 had increased to 150 with an attendance of 600.

In 1855 Fliedner received the degree of doctor in theology from the university of Bonn, in recognition rather of his practical activity than his theological attainments. He scarcely seems, indeed, to have concerned himself with the great controversies which during his lifetime agitated the German Church, his whole life being devoted to steady, well-directed, and eminently successful efforts to benefit the poor, the weak, and the suffering. His character was marked by prompt decision, clear insight, and great practical sagacity. Nor was it without traits of quaint Teutonic humor, which relieved its sterner features.

Fliedner's writings are almost entirely of a practical character. He edited a periodical, *Der Armen und Kranken Freund*, which contained information regarding the various institutions, and also the yearly almanac of the Kaiserswerth institution. Besides purely educational and devotional works, he wrote *Buch der Märtyrer ; Nachricht über das Diakonissen-Werk in der Christ. Kirche ; Die evangel. Märtyrer Ungarns und Siebenbürgens ;* and *Beschreibung der Reise nach Jerusulem und Constantinopel*. All were published at Kaiserswerth. There is a translation of the German life, prepared by the family, by C. Winkworth (London, 1867). On Fliedner and his work see also *Kaiserswerth Deaconesses*, London, 1857 ; Dean Howson's *Deaconesses*, London, 1862 ; *The Service of the Poor*, by E. C. Stephen, London, 1871 ; Stevenson's *Praying and Working*, London, 1865.

FLIGHT, FLYING MACHINES. Of the many scientific problems of modern times, there are few possessing a wider or more enduring interest than that of aërial navigation. To fly has always been an object of ambition with man ; nor will this occasion surprise when we remember the marvellous freedom enjoyed by volant as compared with non-volant animals. The traditions of Dædalus and Icarus illustrate the attempts in the past ; and at the present day societies exist in Britain, France, Austria, and other countries, for the purpose of solving, if possible, the knotty problem. These societies embrace men of the highest scientific attainments, and as they evince great activity, and publish their proceedings at regular intervals, it is not too much to expect that the problem of artificial flight will be actually solved, or at least much simplified. For the first time in the history of the world, the subject of aërial navigation has been taken up in earnest by practical men with the necessary degree of preliminary knowledge and training. Investigators no longer dream about flight : they experiment upon and work towards it. It is, they maintain, a physical problem to be solved by mechanical skill and ingenuity. But while writing thus hopefully, it is necessary to state that as yet no one has succeeded in constructing a fully equipped flying machine. The number of successful flying models, however, is so considerable as to inspire the cultivators of aëronautical science with a very confident hope of success.

The object of the present article is threefold—(1) to demonstrate the laws of natural flight ; (2) to expound the principles on which a flying machine should be constructed ; and (3) to chronicle some of the more important attempts at aërostation in modern times.

It is not necessary to enter upon a history of artificial flight. This has already been done in the article AERONAUTICS, to which the reader is referred. The fact is that aërostation in its modern form dates back only a very few years. It will suffice, then, if the modern discoveries are recorded in the order of time as we proceed.

The subject of aërostation is admitted on all hands to be one of extreme difficulty. To tread upon the air (and this is what is really meant) is, at first sight, in the highest degree utopian; and yet there are thousands of living creatures which actually accomplish this feat. These creatures, however varied in form and structure, all fly according to one and the same principle; and this is a significant fact, as it tends to show that the air must be attacked in a particular way to ensure flight. The flying machine of the future, there can be no doubt, will be constructed on the type of flying animals,—the insect, bird, and bat. It behoves us then at the outset to scrutinize very carefully the general configuration of flying animals, and in particular the size, shape, and movements of their flying organs.

Flying animals, it may be premised, differ entirely from sailing ships and from balloons, with which they are not unfrequently though erroneously compared; and a flying machine constructed upon proper principles can have nothing in common with either of those creations. The ship floats upon water and the balloon upon air; but the ship differs from the balloon, and the ship and the balloon differ from the flying creature and flying machine. The water and air, moreover, have characteristics of their own. The analogies which connect the water with the air, the ship with the balloon, and the ship and the balloon with the flying creature and flying machine are false analogies. A sailing ship is supported by the water and requires merely to be propelled; a flying creature and a flying machine constructed on the living type require to be both supported and propelled. This arises from the fact that water is much denser than air, and because water supports on its surface substances which fall through air.

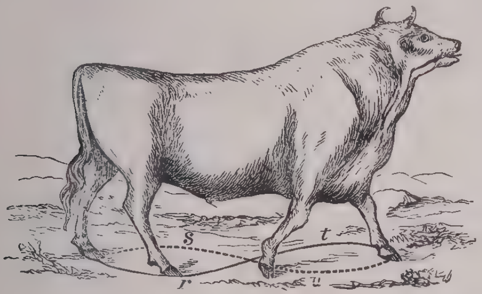

Fig. 1.

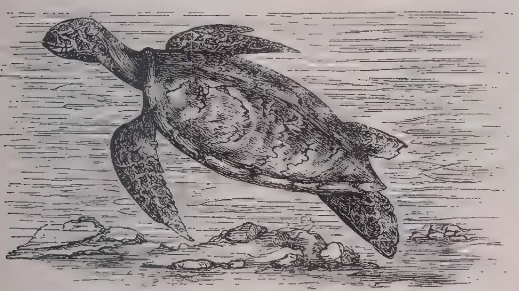

Fig. 2.

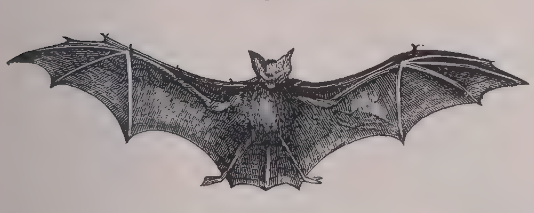

Fig. 3.

FIG. 1.—Chillingham Bull (*Bos Scoticus*). Small travelling extremities adapted for land. *r*, *s*, *t*, *u*, figure-of-8 described by the feet in walking. (Pettigrew, 1867.)

FIG. 2.—The Turtle (*Chelonia imbricata*). Enlarged travelling extremities (flippers) adapted for water. (Pettigrew, 1867.)

FIG. 3.—The Bat (*Phyllocina gracilis*). Greatly expanded travelling extremities adapted for air. (Pettigrew, 1867.)

While water and air are both to be regarded as fluid media, they are to be distinguished from each other in the following particulars. Water is comparatively very heavy, inelastic, and incompressible; air, on the other hand, is comparatively very light, elastic, and compressible. If water be struck with violence, the recoil obtained is great when compared with the recoil obtained from air similarly treated. In water we get a maximum recoil with a minimum of displacement; in air, on the contrary, we obtain a minimum recoil with a maximum of displacement. Water and air when unconfined yield readily to pressure. They thus form *movable fulcra* to bodies acting upon them. In order to meet these peculiarities the travelling organs of aquatic and flying animals (whether they be feet, fins, flippers, or wings) are made not of rigid but of elastic materials. The travelling organs, moreover, increase in size in proportion to the tenuity of the fluid to be acted upon. The difference in size of the travelling organs of animals becomes very marked when the land animals are contrasted with the aquatic, and the aquatic with the aërial, as in figs 1, 2, and 3.

The peculiarities of water and air as supporting media are well illustrated by a reference to swimming, diving, and flying birds. A bird when swimming extends its feet simultaneously or alternately in a backward direction, and so obtains a forward recoil. The water supports the bird, and the feet simply propel. In this case the bird is lighter than the water, and the long axis of the body is horizontal (*a* of fig. 4). When the bird dives, or flies under water, the long axis of the body is inclined obliquely downwards and forwards, and the bird forces itself into and beneath the water by the action of its feet, or wings, or both. In diving or subaquatic flight the feet strike upwards and backwards, the wings downwards and *backwards* (*b* of fig. 4). In aërial flying everything is reversed. The long axis of the bird is inclined obliquely upwards and forwards, and the wings strike, not downwards and backwards, but downwards and *forwards* (*c* of fig. 4). These changes in the direction of the long axis of the bird in swimming, diving, and flying, and in the direction of the stroke of the wings in subaquatic and aërial flight, are due to the fact that the bird is heavier than the air and lighter than the water.

The physical properties of water and air explain in a great measure how the sailing ship differs from the balloon, and how the latter differs from the flying creature and flying machine constructed on the natural type. The sailing ship is, as it were, immersed in two oceans,—viz. an ocean of water and an ocean of air—the former being greatly heavier and denser than the latter. The ocean of water buoys or floats the ship, and the ocean of air, or part of it in motion, swells the sails which propel the ship. The moving air which strikes the sails directly strikes the hull of the vessel indirectly and forces it through the water, which, as explained, is a comparatively dense fluid. When the ship is in motion it can be steered either by the sails alone, or by the rudder alone, or by both combined. A balloon differs from a sailing ship in being immersed in only one ocean, viz., the ocean of air. It resembles the ship in floating upon the air, as the ship floats upon the water; in other words, the balloon is lighter than the air, as the ship is lighter than the water. But here all analogy ceases. The ship, in virtue of its being immersed in two fluids having different densities, can be steered and made to tack about in a horizontal plane in any given direction. This in the case of the balloon, immersed in one fluid, is impossible. The balloon in a calm can only rise and fall in a vertical line. Its horizontal movements, which ought to be the more important, are accidental movements due to air currents, and cannot be controlled; the balloon, in short, cannot be guided. One might as well attempt to steer a boat carried along by currents of water in the absence of oars, sails, and wind, as to steer a balloon carried along by currents of air. The balloon has no hold upon the air, and this consequently cannot be employed as a *fulcrum* for regulating its course. The balloon, because of its vast size and from its being lighter than the air, is completely at the mercy of the wind. It forms an integral part, so to speak, of the wind for the time being, and the direction of the wind in every instance determines the horizontal motion of the balloon. The force required to propel a balloon against even a moderate breeze would result in its destruction. The balloon cannot be transferred with any degree of certainty from one point of the earth's surface to another, and hence the chief danger in its employment. It may, quite as likely as not, carry its occupants out to sea. The balloon is a mere lifting machine. It has no analogue in nature, and, as its history sufficiently shows, is incapable of improvement.

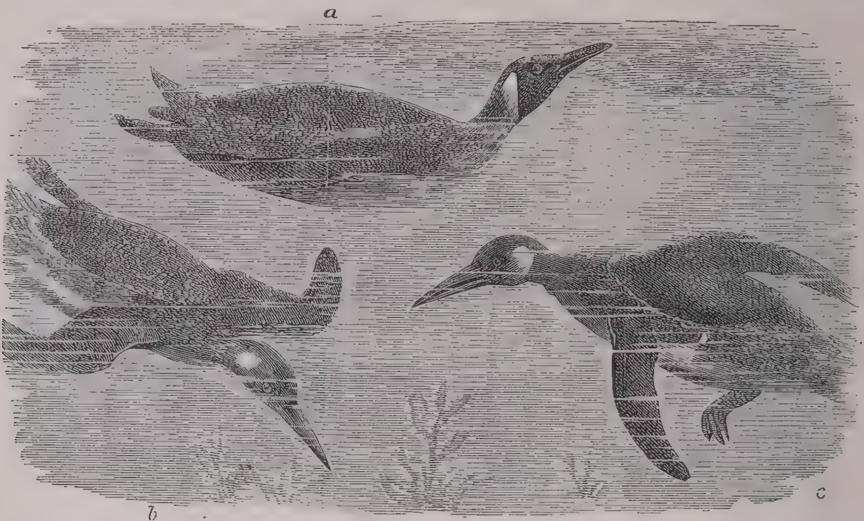

Fig. 4.—The King Penguin in the positions assumed by a bird in (*a*) swimming, (*b*) diving, and (*c*) flying. (Pettigrew.)

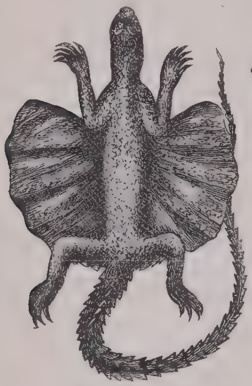

Fig. 5.

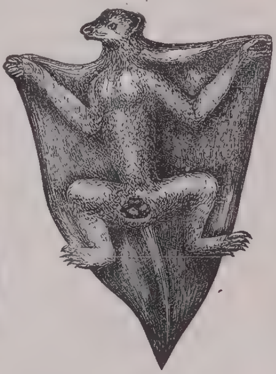

Fig. 6.

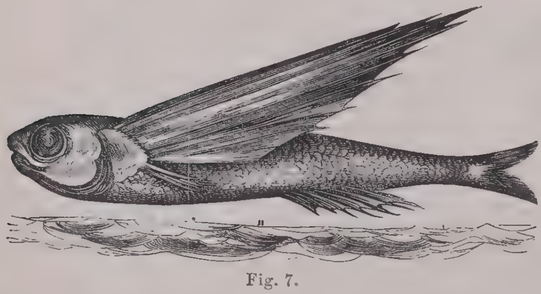

Fig. 7.

Fig. 5.—The Red-throated Dragon (*Draco hæmatopogon*). (Pettigrew, 1867.)
Fig. 6.—The Flying Colugo (*Galeopithecus volans*); also called flying lemur and flying squirrel. (Pettigrew, 1867.)
Fig. 7.—The Flying Fish (*Exocœtus exiliens*). (Pettigrew, 1867.)

The balloon, as is well known, was introduced by the Montgolfier brothers in 1782. It was first inflated by heated air obtained by burning trusses of straw under it, then by hydrogen gas, and lastly by coal gas. It is in no sense to be regarded a flying machine. It resembles the flying creature only in this, that it is immersed in the ocean of air in which it sustains itself. The mode of suspension is wholly different. The balloon floats because it is lighter than the air; the flying creature floats because it extracts from the air, by the vigorous downward action of its wings, a certain amount of upward recoil. The balloon is passive; the flying creature is active. The balloon is controlled by the wind; the flying creature controls the wind. The balloon in the absence of wind can only rise and fall in a vertical line; the flying creature can fly in a horizontal plane in any given direction. The balloon is inefficient because of its levity; the flying creature is efficient because of its weight.

Weight, however paradoxical it may appear, is necessary to flight. Everything which flies is vastly heavier than the air. The inertia of the mass of the flying creature enables it to control and direct its movements in the air. Many are of opinion that flight is a mere matter of levity and power. This is quite a mistake. No machine, however light and powerful, will ever fly whose travelling surfaces are not properly fashioned and properly applied to the air.

It was supposed at one time that the air sacs of birds contributed in some mysterious way to flight, but this is now known to be erroneous. The bats and some of the best flying birds have no air sacs. Similar remarks are to be made of the heated air imprisoned within the bones of certain birds.[1] Feathers even are not necessary to flight. Insects and bats have no feathers, and yet fly well. The only facts in natural history which appear even indirectly to countenance the flotation theory are the presence of a swimming bladder in some fishes, and the existence of membranous expansions or pseudo-wings in certain animals, such as the flying fish, flying dragon, and flying squirrel. As, however, the animals referred to do not actually fly, but merely dart into the air and there sustain themselves for brief intervals, they afford no real support to the theory. The so-called floating animals are well depicted at figs. 5, 6, and 7.

---

[1] According to Dr. Crisp, the swallow, martin, snipe, and many birds of passage have no air in their bones.—*Proc. Zool. Soc., Lond.*, part xxv., 1857, p. 13.

It has been asserted, and with some degree of plausibility, that a fish lighter than the water might swim, and that a bird lighter than the air might fly; it ought, however, to be borne in mind that, in point of fact, a fish lighter than the water could not hold its own if the water were in the least perturbed, and that a bird lighter than the air would be swept into space by even a moderate breeze without hope of return. Weight and power are always associated in living animals, and the fact that living animals are made heavier than the medium they are to navigate may be regarded as a conclusive argument in favor of weight being necessary alike to the swimming of the fish and the flying of the bird. It may be stated once for all that flying creatures are for the most part as heavy, bulk for bulk, as other animals, and that flight in every instance is the product, not of superior levity, but of *weight* and *power* directed upon properly constructed flying organs.

This fact is important as bearing on the construction of flying machines. It shows that a flying machine need not necessarily be a light, airy structure exposing an immoderate amount of surface. On the contrary, it favors the belief that it should be a compact and moderately heavy and powerful structure, which trusts for elevation and propulsion entirely to its flying appliances—whether actively moving wings, or screws, or aëro-planes wedged forward by screws. It should attack and subdue the air, and never give the air an opportunity of attacking or subduing it. It should smite the air intelligently and as a master, and its vigorous well-directed thrusts should in every instance elicit an upward and forward recoil. The flying machine of the future, there is reason to believe, will be a veritable example of "*multum in parvo*." It will launch itself in the ocean of air, and will extract from that air, by means of its travelling surfaces—however fashioned and however applied—the recoil or resistance necessary to elevate and carry it forward. Extensive inert surfaces indeed are contra-indicated in a flying machine, as they approximate it to the balloon, which, as has been shown, cannot maintain its position in the air if there are air currents. A flying machine which could not face air currents would necessarily be a failure. To obviate this difficulty we are forced to fall back upon *weight*, or rather the structures and appliances which weight represents. These appliances as indicated should not be unnecessarily expanded, but when expanded they should, wherever practicable, be converted into actively moving flying surfaces, in preference to fixed or inert dead surfaces.

The question of surface is a very important one in aërostation; it naturally resolves itself into one of active and passive surface. As there are active and passive surfaces in the flying animal, so there are, or should be, active and passive surfaces in the flying machine. Art should follow nature in this matter. The active surfaces in flying creatures are always greatly in excess of the passive ones, from the fact that the former virtually increase in proportion to the spaces through which they are made to travel. Nature not only distinguishes between active and passive surfaces in flying animals, but she strikes a just balance between them, and utilizes both. She regulates the surfaces to the strength and weight of the flying creature and the air currents to which the surfaces are to be exposed and upon which they are to operate. In her calculations she never forgets that her flying subjects are to control and not to be controlled by the air. As a rule she reduces the passive surfaces of the body to a minimum; she likewise reduces as far as possible the actively moving or flying surfaces. While, however, diminishing the surfaces of the flying animal as a whole, she increases as occasion demands the active or wing surfaces by wing movements, and the passive or dead surfaces by the forward motion of the body in progressive flight. She knows that if the wings are driven with sufficient rapidity they practically convert the spaces through which they move into solid bases of support; she also knows that the body in rapid flight derives support from all the air over which it passes. The manner in which the wing surfaces are increased by the wing movements will be readily understood from the accompanying illustrations of the blow fly with its wings at rest and in motion (figs. 8 and 9). In fig. 8 the surfaces exposed by the body of the insect and the wings are, as compared with those of fig. 9, trifling. The wind would have much less purchase on fig. 8 than on fig. 9, provided the surfaces exposed by the latter were passive or dead surfaces. But they are not dead surfaces; they represent the spaces occupied by the rapidly vibrating wings, which are actively moving flying organs. As, moreover, the wings travel at a much higher speed than any wind that blows, they are superior to and control the wind; they enable the insect to dart through the wind in whatever direction it pleases.

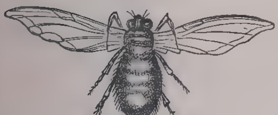

Fig. 8.

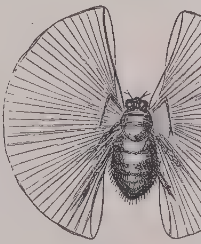

Fig. 9.

Fig. 8.—Blow Fly (*Musca vomitoria*) with its wings at rest. (Pettigrew.)
Fig. 9.—Blow Fly with its wings in motion as in flight. (Pettigrew.)

The reader has only to imagine figs. 8 and 9 cut out in paper to realize that extensive, inert, horizontal aëro-planes[1] in a flying machine would be a mistake. It is found to be so practically, as will be shown by and by. Fig. 9 so cut out would be heavier than fig. 8, and if both were exposed to a current of air, fig. 9 would be more blown about than fig. 8.

It is true that in beetles and certain other insects there are the elytra or wing cases—thin, light, horny structures—which in the act of flight are extended horizontally and act as sustainers or gliders. The elytra, however, are comparatively long narrow structures which occupy a position in front of the wings, of which they may be regarded as forming the anterior parts. The elytra are to the delicate wings of some insects what the thick anterior margins are to stronger wings. The elytra, moreover, are not wholly passive structures. They can be moved, and the angles made by their under surfaces with the horizon adjusted. Finally, they are not essential to flight, as flight in the great majority of instances is performed without them. The elytra serve as protectors to the wings when the wings are folded upon the back of the insect, and as they are extended horizontally when the insect is flying they contribute to flight indirectly, in virtue of their being carried forward by the body in motion.

The manner in which the wings of the insect traverse the air, so as practically to increase the basis of support, raises the whole subject of natural flight. It is necessary, therefore, at this stage to direct the attention of the reader somewhat fully to the subject of flight, as witnessed in the insect, bat, and bird,—a knowledge of natural flight preceding, and being in some senses indispensable to, a knowledge of artificial flight.

The bodies of flying creatures are, as a rule, very strong, comparatively light, and of an elongated form,—the bodies of birds being specially adapted for cleaving the air. Flying creatures, however, are less remarkable for their strength, shape, and comparative levity than for the size and extraordinarily rapid and complicated movements of their wings. To Professor J. Bell Pettigrew is due the merit of having first satisfactorily analyzed those movements, and of having reproduced them by the aid of artificial wings. This physiologist in 1867[2] showed that all natural wings, whether of the insect, bat, or bird, are screws structurally, and that they act as screws when they are made to vibrate, from the fact that they twist in opposite directions during the down and up strokes. He also explained that all wings act upon a common principle, and that they present oblique, kite-like surfaces to the air, through which they pass much in the same way that an oar passes through water in sculling. He further pointed out that the wings of flying creatures (contrary to received opinions, and as has been already indicated) strike downwards and forwards during the down strokes, and upwards and forwards during the up strokes. Lastly, and most important of all, he demonstrated that the wings of flying creatures, when the bodies of said creatures are fixed, describe *figure-of-8 tracks* in space,—the figure-of-8 tracks, when the bodies are released and advancing as in rapid flight, being opened out and converted into *waved tracks*.

---

[1] By the term aëro-plane is meant a thin, light, expanded structure intended to float or rest upon the air, and calculated to afford a certain amount of support to any body attached to it.

[2] "On the various modes of Flight in relation to Aëronautics," by J. Bell Pettigrew, M.D., F.R.S., etc. (*Proceedings of the Royal Institution of Great Britain*, March 22d, 1867): "On the Mechanical Appliances by which Flight is attained in the Animal Kingdom," by the same author (*Transactions of the Linnæan Society*, vol. xxvi., read June 6th and 20th, 1867).

Professor Pettigrew's discovery of the figure-of-8 and waved movements, concerning which so much has been said and written, was confirmed some two years after it was made by Professor E. J. Marey[1] by the aid of the "sphygmograph."[2] The movements in question are now regarded as fundamental, from the fact that they are alike essential to natural and artificial flight.

The following is Professor Pettigrew's description of wings and wing movements published in 1867:—

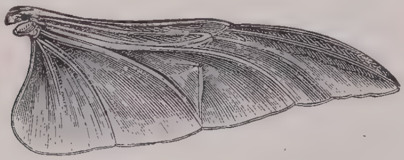

Fig. 10.

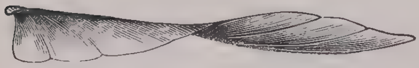

Fig. 11.

FIG. 10.—Right wing of the Beetle (*Goliathus micans*) when at rest; seen from above. (Pettigrew, 1867.)

FIG. 11.—Right wing of the Beetle (*Goliathus micans*) when in motion; seen from behind. This figure shows how the wing twists and untwists when in action, and how it forms a true screw. (Pettigrew, 1867.)

"The wings of insects and birds are, as a rule, more or less triangular in shape, the base of the triangle being directed towards the body, its sides anteriorly and posteriorly. They are also conical on section from within outwards and from before backwards, this shape converting the pinions into delicately-graduated instruments balanced with the utmost nicety to satisfy the requirements of the muscular system on the one hand and the resistance and resiliency of the air on the other. While all wings are graduated as explained, innumerable varieties occur as to their general contour, some being falcated or scythe-like, others oblong, others rounded or circular, some lanceolate, and some linear. The wings of insects may consist either of one or two pairs,—the anterior or upper pair, when two are present, being in some instances greatly modified and presenting a corneous condition. They are then known as elytra, from the Greek ἔλυτρον, a sheath. Both pairs are composed of a duplicature of the integument or investing membrane, and are strengthened in various directions by a system of hollow, horny tubes, known to entomologists as the neuræ or nervures. These nervures taper towards the extremity of the wing, and are strongest towards its root and anterior margin, where they supply the place of the arm in bats and birds. The neuræ are arranged at the axis of the wing after the manner of a fan or spiral stair—the anterior one occupying a higher position than that farther back, and so of the others. As this arrangement extends also to the margins, *the wings are more or less twisted upon themselves*, and present a certain degree of convexity on their superior or upper surface, and a corresponding concavity on their inferior or under surface—their free edges supplying those fine curves which act with such efficacy upon the air in obtaining the maximum of resistance and the minimum of displacement. As illustrative examples of the form of wings alluded to, those of the beetle, bee, and fly may be cited—the pinions in those insects acting as *helices*, or *twisted levers*, and elevating weights much greater than the area of the wings would seem to warrant" (figs. 10 and 11). . . . "To confer on the wings the multiplicity of movements which they require, they are supplied with double hinge or compound joints, which enable them to move not only in an upward, downward, forward, and backward direction, but also at various intermediate degrees of obliquity. An insect with wings thus hinged may, as far as steadiness of body is concerned, be not inaptly compared to a compass set upon gimbals, where the universality of motion in one direction ensures comparative fixedness in another." . . . "All wings obtain their leverage by presenting oblique surfaces to the air, the degree of obliquity gradually increasing in a direction from behind, forwards and downwards, during extension when the sudden or effective stroke is being given, and gradually decreasing in an opposite direction during flexion, or when the wing is being more slowly recovered preparatory to making a second stroke. The effective stroke in insects, and this holds true also of birds, is therefore delivered *downwards and forwards*, and not, as the majority of writers believe, vertically, or even slightly backwards. . . . The wing in the insect is more flattened than in the bird; and advantage is taken on some occasions of this circumstance, particularly in heavy-bodied, small-winged, quick-flying insects, *to reverse the pinion more or less completely during the down and up strokes*." . . . "This is effected in the following manner. The posterior margin of the wing is made to rotate, during the down stroke, in a direction from above downwards and from behind forwards,—the anterior margin travelling in an opposite direction and reciprocating. The wing may thus be said to attack the air by a *screwing movement* from above. During the up or return stroke, on the other hand, the posterior margin rotates in a direction from below upwards and from before backwards, so that by a similar but *reverse screwing motion* the pinion attacks the air from beneath." . . . "*A figure-of-8*, compressed laterally and placed obliquely with its long axis running from left to right of the spectator, represents the movements in question. *The down and up strokes*, as will be seen from this account, *cross each other*, the wing smiting the air during its descent from above, as in the bird and bat, and during its ascent from below as in the flying fish and boy's kite" (fig. 12).

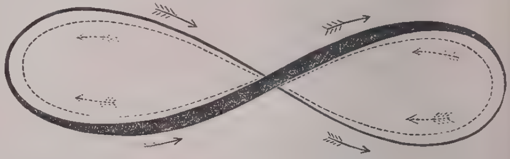

FIG. 12 shows the figure-of-8 made by the margins of the wing in extension (continuous line), and flexion (dotted line). As the tip of the wing is midway between its margins, a line between the continuous and dotted lines gives the figure-of-8 made by the tip. The arrows indicate the reversal of the planes of the wing, and show how the down and up strokes *cross each other*. (Pettigrew, 1867.)

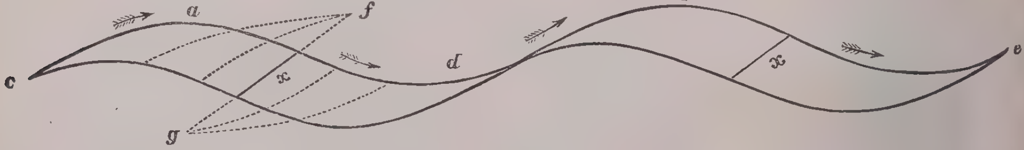

FIG. 13.—Wave track made by the wing in progressive flight. *a*, *b*, crests of the wave; *c*, *d*, *e*, up strokes; *x*, *x*, down strokes; *f*, point corresponding to the anterior margin of the wing, and forming a centre for the downward rotation of the wing (*a*, *g*); *g*, point corresponding to the posterior margin of the wing, and forming a centre for the upward rotation of the wing (*d*, *f*). (Pettigrew, 1867.)

. . . "The figure-of-8 action of the wing explains how an insect or bird may fix itself in the air, the backward and forward reciprocating action of the pinion affording support, but no propulsion. In these instances the backward and forward strokes are made to counterbalance each other. Although the figure-of-8 represents with considerable fidelity the twisting of the wing upon its axis during extension and flexion, when the insect is playing its wings before an object, or still better when it is artificially fixed, it is otherwise when the down stroke is added and the insect is fairly on the wing and progressing rapidly. In this case the wing, in virtue of its being carried forward by the body in motion, describes an undulating or spiral course. as shown in fig. 13."

---

[1] *Revue des Cours Scientifiques de la France et de l'Étranger*, 1869.

[2] The sphygmograph, as its name indicates, is a recording instrument. It consists of a smoked cylinder revolving by means of clock work at a known speed, and a style or pen which inscribes its surface by scratching or brushing away the lampblack. The movements to be registered are transferred to the style or pen by one or more levers, and the pen in turn transfers them to the cylinder, where they appear as legible tracings. In registering the movements of the wings, the tips and margins of the pinions were, by an ingenious modification, employed as the styles or pens. By this arrangement the different parts of the wings were made actually to record their own movements. As will be seen from this account, the figure-of-8 or wave theory of stationary and progressive flight has been made the subject of a rigorous *experimentum crucis*.

. . . "The down and up strokes are compound movements—the termination of the down stroke embracing the beginning of the up stroke, and the termination of the up stroke including the beginning of the down stroke. This is necessary in order that the down and up strokes may glide into each other in such a manner as to prevent jerking and unnecessary retardation."[1] . . .

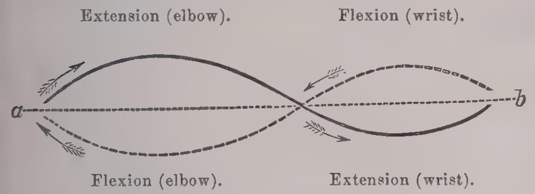

FIG. 14.—*a*, *b*, line along which the wing travels during extension and flexion. The arrows indicate the direction in which the wing is spread out in extension and closed or folded in flexion. (Pettigrew, 1867.)

"The wing of the bird, like that of the insect, is concavo-convex, and *more or less twisted upon itself* when extended, so that the anterior or thick margin of the pinion presents a different degree of curvature to that of the posterior or thin margin. This twisting is in a great measure owing to the manner in which the bones of the wing are twisted upon themselves, and the spiral nature of their articular surfaces,—the long axes of the joints always intersecting each other at right angles, and the bones of the elbow and wrist making a quarter of a turn or so during extension and the same amount during flexion. As a result of this disposition of the articular surfaces, the wing may be shot out or extended, and retracted or flexed in nearly the same plane, the bones composing the wing rotating on their axes during either movement (fig. 14). The secondary action or the revolving of the component bones on their own axes, is of the greatest importance in the movements of the wing, as it communicates to the hand and forearm, and consequently to the primary and secondary feathers which they bear, the precise angles necessary for flight. It in fact ensures that the wing, and the curtain or fringe of the wing which the primary and secondary feathers form, shall be screwed into and down upon the wind in extension, and unscrewed or withdrawn from the wind during flexion. The wing of the bird may therefore be compared to a huge gimlet or auger, the axis of the gimlet representing the bones of the wing, the flanges or spiral thread of the gimlet the primary and secondary feathers" (figs. 15 and 16). . . . "From this description it will be evident that by the mere rotation of the bones of the forearm and hand the maximum and minimum of resistance is secured much in the same way that this object is attained by the alternate dipping and feathering of an oar." . . . "The wing, both when at rest and when in motion, may not inaptly be compared to the blade of an ordinary screw propeller as employed in navigation. Thus the general outline of the wing corresponds closely with the outline of the propeller (figs. 11, 16, and 18), and the track described by the wing in space *is twisted upon itself* propeller fashion[2] (figs. 12, 20, 21, 22, 23). The great velocity with which the wing is driven converts the impression or blur into what is equivalent to a solid for the time being, in the same way that the spokes of a wheel in violent motion, as is well understood, more or less completely occupy the space contained within the rim or circumference of the wheel" (figs. 9, 20, and 21).

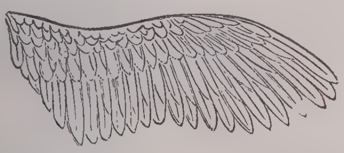

FIG. 15.—Right wing of the Red-legged Partridge (*Perdix rubra*). Dorsal aspect as seen from above. (Pettigrew, 1867.)

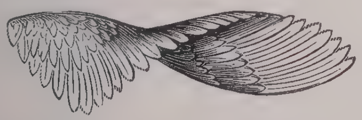

FIG. 16.—Right wing of the Red-legged Partridge (*Perdix rubra*). Dorsal and ventral aspects as seen from behind; showing auger-like conformation of wing. Compare with figs. 11 and 18. (Pettigrew, 1867.)

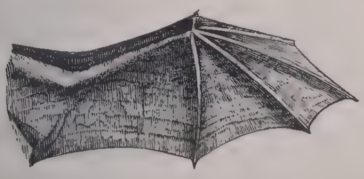

FIG. 17.—Right wing of the Bat (*Phyllocina gracilis*). Dorsal aspect as seen from above. (Pettigrew, 1867.)

. . . "The wing of the bat bears considerable resemblance to that of the insect, inasmuch as it consists of a delicate, semi-transparent, continuous membrane, supported in divers directions, particularly towards its anterior margin, by a system of stays or stretchers which confer upon it the degree of rigidity requisite for flight. It is, as a rule, deeply concave on its under or ventral surface, and in this respect resembles the wing of the heavy-bodied birds. The movement of the bat's wing in extension is a *spiral* one, the spiral running alternately from below upwards and forwards and from above downwards and backwards. The action of the wing of the bat, and the movements of its component bones, are essentially the same as in the bird" (figs. 17 and 18).

. . . "The wing strikes the air precisely as a boy's kite would if it were jerked by its string, the only difference being that the kite is *pulled forwards* upon the wind by the string and the hand, whereas in the insect, bat, and bird the wing is *pushed forwards* on the wind by the weight of the body and the power residing in the pinion itself" (fig. 19).[3]

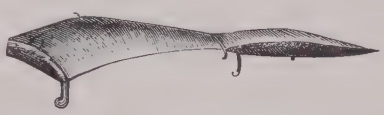

FIG. 18.—Right wing of the Bat (*Phyllocina gracilis*). Dorsal and ventral aspects, as seen from behind. These show the screw-like configuration of the wing, and also shows how the wing twists and untwists during its action. (Pettigrew, 1867.)

The figure-of-8 and kite-like action of the wing referred to lead us to explain how it happens that the wing, which in many instances is a comparatively small and delicate organ, can yet attack the air with such vigor as to extract from it the recoil necessary to elevate and propel the flying creature. The accompanying figures from one of Professor Pettigrew's more recent memoirs[4] will serve to explain the *rationale* (figs. 20, 21, 22, and 23).

As will be seen from these figures, the wing during its vibration sweeps through a comparatively very large space.

---

[1] This continuity of the down into the up stroke and the converse is greatly facilitated by the elastic ligaments at the root or in the substance of the wing. These assist in elevating, and, when necessary, in flexing and elevating it. They counteract in some measure what may be regarded as the dead weight of the wing, and are especially useful in giving it continuous play.

[2] "The importance of the twisted configuration or screw-like form cannot be over-estimated. That this shape is intimately associated with flight is apparent from the fact that the rowing feathers of the wing of the bird are every one of them distinctly spiral in their nature; in fact, one entire rowing feather is equivalent—morphologically and physiologically—to one entire insect wing. In the wing of the martin, where the bones of the pinion are short, and in some respects rudimentary, the primary and secondary feathers are greatly developed, and banked up in such a manner that the wing as a whole presents the same curves as those displayed by the insect's wing, or by the wing of the eagle, where the bones, muscles, and feathers have attained a maximum development. The conformation of the wing is such that it presents a waved appearance in every direction,—the waves running longitudinally, transversely, and obliquely. The greater portion of the wing may consequently be removed without essentially altering either its form or its functions. This is proved by making sections in various directions, and by finding that in some instances as much as two-thirds of the wing may be lopped off without materially impairing the power of flight" (*Trans. Roy. Soc. Edin.*, vol. xxvi. pp. 325, 326).

[3] "On the various modes of Flight in relation to Aëronautics" (*Proceedings of the Royal Institution of Great Britain*, March 22d, 1867); "On the Mechanical Appliances by which Flight is attained in the Animal Kingdom" (*Transactions of the Linnean Society*, vol. xxvi., read June 6th and 20th, 1867), by J. Bell Pettigrew, M.D., F.R.S., Professor of Medicine and Anatomy, University of St. Andrews.

[4] "On the Physiology of Wings; being an analysis of the movements by which flight is produced in the Insect, Bat, and Bird" (*Trans. Roy. Soc. Edin.*, vol. xxvi.).

This space, as already explained, is practically a solid basis of support for the wing and for the flying animal. The wing attacks the air in such a manner as virtually to have no slip,—this for two reasons. The wing reverses instantly and acts as a kite during nearly the entire down and up strokes. The angles, moreover, made by the wing with the horizon during the down and up strokes are at no two intervals the same, but (and this is a remarkable circumstance) they are always adapted to the speed at which the wing is travelling for the time being. The increase and decrease in the angles made by the wing as it hastens to and fro are due partly to the resistance offered by the air, and partly to the mechanism and mode of application of the wing to the air. The wing, during its vibrations, rotates upon two separate centres, the tip rotating round the root of the wing as an axis (short axis of wing), the posterior margin rotating around the anterior margin (long axis of wing). The wing is really eccentric in its nature, a remark which applies also to the rowing feathers of the bird's wing. The compound rotation goes on throughout the entire down and up strokes, and is intimately associated with the power which the wing enjoys of alternately seizing and evading the air.

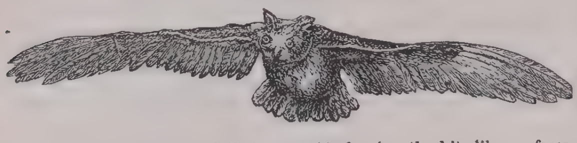

Fig. 19.—The Cape Barn-owl (*Strix capensis*), showing the kite-like surfaces presented by the ventral aspect of the wings and body in flight. (Pettigrew, 1867.)

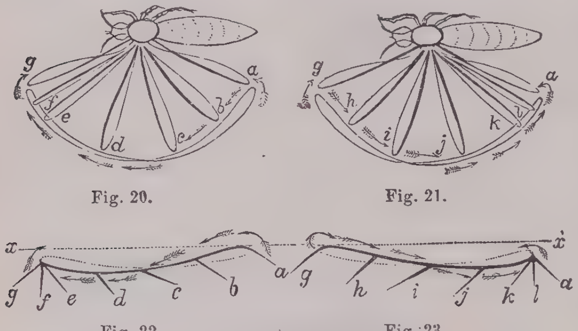

Fig. 20. Fig. 21.

Fig. 22. Fig. 23.

Figs. 20, 21, 22, and 23 show the area mapped out by the left wing of the Wasp when the insect is fixed and the wing made to vibrate. These figures illustrate the various angles made by the wing with the horizon as it hastens to and fro, and show how the wing reverses and reciprocates, and how it twists upon itself in opposite directions, and describes a figure-of-8 track in space. Figs. 20 and 22 represent the forward or down stroke (*a b c d e f g*), figs. 21 and 23 the backward or up stroke (*g h i j k l a*). The terms forward and back strokes are here employed with reference to the head of the insect. *x x′*, line to represent the horizon. If fig. 22, representing the down or forward stroke, be placed upon fig. 23, representing the up or backward stroke, it will be seen that *the wing crosses its own track* more or less completely at every stage of the down and up strokes. (Pettigrew, 1870.)

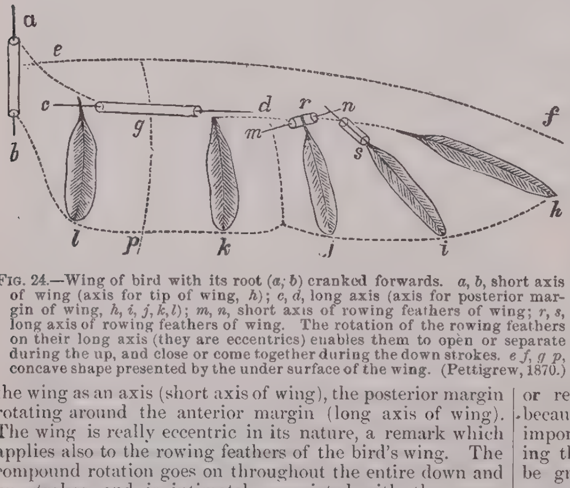

Fig. 24.—Wing of bird with its root (*a*, *b*) cranked forwards. *a*, *b*, short axis of wing (axis for tip of wing, *h*); *c*, *d*, long axis (axis for posterior margin of wing, *h*, *i*, *j*, *k*, *l*); *m*, *n*, short axis of rowing feathers of wing; *r*, *s*, long axis of rowing feathers of wing. The rotation of the rowing feathers on their long axis (they are eccentrics) enables them to open or separate during the up, and close or come together during the down strokes. *e f*, *g p*, concave shape presented by the under surface of the wing. (Pettigrew, 1870.)

The compound rotation of the wing is greatly facilitated by the wing being elastic and flexible. It is this which causes the wing to twist and untwist diagonally on its long axis when it is made to vibrate. The twisting referred to is partly a vital and partly a mechanical act;—that is, it is occasioned in part by the action of the muscles and in part by the greater resistance experienced from the air by the tip and posterior margin of the wing as compared with the root and anterior margin,—the resistance experienced by the tip and posterior margin causing them to reverse always subsequently to the root and anterior margin, which has the effect of throwing the anterior and posterior margins of the wing into figure-of-8 curves, as shown at figs. 9, 11, 12, 16, 18, 20, and 21.

The compound rotation of the wing, as seen in the bird, is represented in fig. 24.

Not the least curious feature of the wing movements is the remarkable power which the wing possesses of making and utilizing its own currents. Thus, when the wing descends it draws after it a strong current, which, being met by the wing during its ascent, greatly increases the efficacy of the up stroke. Similarly and conversely when the wing ascends, it creates an upward current, which, being met by the wing when it descends, powerfully contributes to the efficiency of the down stroke. This statement can be readily verified by experiment both with natural and artificial wings. Neither the up nor the down strokes are complete in themselves.

The wing to act efficiently must be driven at a certain speed, and in such a manner that the down and up strokes shall glide into each other. It is only in this way that the air can be made to pulsate, and that the rhythm of the wing and the air waves can be made to correspond. The air must be seized and let go in a certain order and at a certain speed to extract a maximum recoil. The rapidity of the wing movements is regulated by the size of the wing, small wings being driven at a very much higher speed than larger ones. The different parts of the wing, moreover, are made to travel at different degrees of velocity—the tip and posterior margin of the wing always rushing through a much greater space in a given time than the root and anterior margin.

The rapidity of travel of the insect wing is in some cases enormous. The wasp, for instance, is said to ply its wings at the rate of 110, and the common housefly at the rate of 330 beats per second. Quick as are the vibrations of natural wings, the speed of certain parts of the wing is amazingly increased. Wings as a rule are long and narrow. As a consequence, a comparatively slow and very limited movement at the root confers great range and immense speed at the tip, the speed of each portion of the wing increasing as the root of the wing is receded from. This is explained on a principle well understood in mechanics, viz., that when a wing or rod hinged at one end is made to move in a circle, the tip or free end of the wing or rod describes a much wider circle in a given time than a portion of the wing or rod nearer the hinge (fig. 25).

One naturally inquires why the high speed of wings and why the progressive increase of speed at their tips and posterior margins. The answer is not far to seek. If the wings were not driven at a high speed, and if they were not eccentrics made to revolve upon two separate axes, they would of necessity be large cumbrous structures; but large heavy wings would be difficult to work, and what is worse, they would (if too large), instead of controlling the air, be controlled by it, and so cease to be flying organs.

There is, however, another reason why wings should be made to vibrate at high speeds. The air, as explained, is a very light thin, elastic medium, which yields on the slightest pressure, and unless the wings attacked it with great violence the necessary recoil or resistance could not be obtained. The atmosphere, because of its great tenuity, mobility, and comparative imponderability, presents little resistance to bodies passing through it at low velocities. If, however, the speed be greatly accelerated, the action of even an ordinary cane is sufficient to elicit a recoil. This comes of the action and reaction of matter, the resistance experienced varying according to the density of the atmosphere and the shape, extent, and velocity of the body acting upon it. While, therefore, scarcely any impediment is offered to the progress of an animal in motion in the air, it is often exceedingly difficult to compress the air with sufficient rapidity and energy to convert it into a suitable fulcrum for securing the onward impetus. This arises from the fact that bodies moving in air experience a *minimum of resistance* and occasion a *maximum of displacement*. Another and very obvious difficulty is traceable to the great disparity in the weight of air as compared with any known solid, and the consequent want of buoying or sustaining power which that disparity involves. If we compare air with water we find it is nearly 1000 times lighter. To meet these peculiarities the insect, bat, and bird are furnished with extensive flying surfaces in the shape of wings, which they apply with singular velocity and power to the air, as levers of the third order. In this form of lever, as the reader is aware, the power is applied between the fulcrum and the weight to be raised. The power is represented by the wing, the fulcrum by the air, and the weight by the body of the flying animal. Although the third order of lever is particularly inefficient when the fulcrum is rigid and immobile, it possesses singular advantages when these conditions are reversed, that is, when the fulcrum, as happens with the air, is *elastic* and *yielding*. In this instance a very slight movement at the root of the pinion, or that end of the lever directed towards the body, is followed by an immense sweep of the extremity of the wing, where its elevating and propelling power is greatest,—this arrangement insuring that the large quantity of air necessary for propulsion and support shall be compressed under the most favorable conditions.

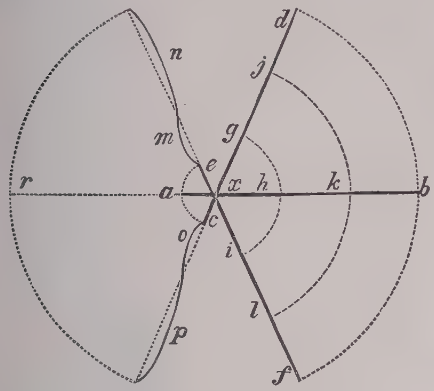

Fig. 25 shows how different portions of the wing travel at different degrees of speed. In this figure the rod $a\ b$, hinged at x, represents the wing. When the wing is made to vibrate, its several portions travel through the spaces $d\ b\ f$, $j\ k\ l$, $g\ h\ i$, and $e\ a\ c$ in exactly the same interval of time. The part of the wing marked b, and which corresponds with the tip, consequently travels very much more rapidly than the part marked a, which corresponds with the root. $m\ n$, $o\ p$, curves made by the wing at the end of the up and down strokes; r, position of the wing at the middle of the stroke. (Pettigrew, 1870.)

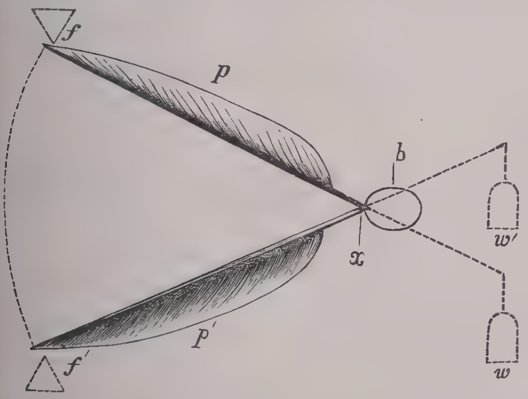

Fig. 26.—In this figure f, f' represent the movable fulcra furnished by the air, p, p' the power residing in the wing, and b the body to be moved. In order to make the problem of flight more intelligible, the lever formed by the wing is prolonged beyond the body (b), and to the root of the wing so extended the weight (w, w') is attached; x represents the universal joint by which the wing is attached to the body. When the wing ascends as shown at p, the air (fulcrum f) resists its upward passage, and forces the body (b) or its representative (w) slightly downwards. When the wing descends as shown at p', the air (fulcrum f') resists its downward passage, and forces the body (b) or its representative (w') slightly upwards. From this it follows that when the wing rises the body falls, and *vice versâ*,—the wing describing the arc of a large circle (f, f'), the body (b), or the weights (w, w') representing it, describing the arc of a small circle. (Pettigrew, 1873.)

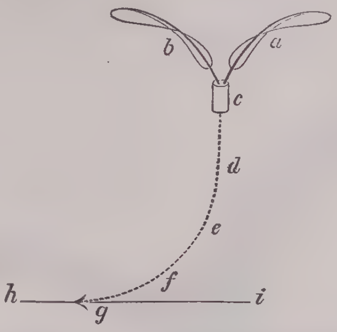

Fig. 27.—a, b, quill feathers; c, cork; d, e, f, g, downward and *forward* curved trajectory made by the feathers and cork before reaching the ground (h, i). (Pettigrew, 1870.)

In this process the weight of the body performs an important part, by acting upon the inclined planes formed by the wings in the plain of progression. The power and the weight may thus be said to reciprocate, the two sitting, as it were, side by side and blending their peculiar influences to produce a common result, as indicated at fig. 26.

When the wings descend they elevate the body, the wings being active and the body passive; when the body descends it contributes to the elevation of the wings,[1] the body being active and the wings passive. It is in this way that weight forms a factor in flight, the wings and the weight of the body reciprocating and mutually assisting and relieving each other. This is an argument for employing four wings in artificial flight,—the wings being so arranged that the two which are up shall always by their fall mechanically elevate the two which are down. Such an arrangement is calculated greatly to conserve the driving power, and, as a consequence, to reduce the weight.

That the weight of the body plays an important part in the production of flight may be proved by a very simple experiment. If two quill feathers are fixed in an ordinary cork, and so arranged that they expand and arch above it, it is found that if the apparatus be dropped from a vertical height of three yards it does not fall vertically downwards, but downwards and *forwards* in a curve, the forward travel amounting in some instances to a yard and a half. Here the cork in falling acts upon the feathers (which are to all intents and purposes wings), and these in turn act upon the air, in such a manner as to produce a horizontal transference. The apparatus which formed the subject of the present experiment is represented at fig. 27.

In order to utilize the air as a means of transit, the body in motion, whether it moves in virtue of the life it possesses, or because of a force superadded, must be heavier than air. It must tread and rise upon the air as a swimmer upon the water, or as a kite upon the wind. This is necessary for the simple reason that the body must be active, the air passive. The flying body must act against gravitation, and elevate and carry itself forward at the expense of the air and of the force which resides in it, whatever that may be. If it were otherwise—if it were rescued from the law of gravitation on the one hand, and bereft of independent movement on the other, it would float about uncontrolled and uncontrollable like an ordinary balloon.

---

[1] The other forces which assist in elevating the wings are—(a) the elevator muscles of the wings, (b) the elastic properties of the wings, and (c) the reaction of the compressed air on the under surfaces of the wings.

In flight one of two things is necessary. Either the wings must attack the air with great violence, or the air in rapid motion must attack the wings: either suffices. If a bird attempts to fly in a calm, the wings must be made to smite the air after the manner of a boy's kite with great vigor and at a high speed. In this case the wings fly the bird. If, however, the bird is fairly launched in space and a stiff breeze is blowing, all that is required in many instances is to extend the wings at a slight upward angle to the horizon so that the under parts of the wings present kite-like surfaces. Under these circumstances the rapidly moving air flies the bird. The flight of the albatross supplies the necessary illustration. If by any chance this magnificent bird alights upon the sea he must flap and beat the water and air with his wings with tremendous energy until he gets fairly launched. This done he extends his enormous pinions[1] and sails majestically along, seldom deigning to flap his wings, the breeze doing the work for him. A familiar illustration of the same principle may be witnessed any day when children are engaged in their favorite pastime of kite-flying. If two boys attempt to fly a kite in a calm, the one must hold up the kite and let go when the other runs. In this case the under surface of the kite is made to strike the still air. If, however, a stiff autumn breeze be blowing, it suffices if the boy who formerly ran when the kite was let go stands still. In this case the air in rapid motion strikes the under surface of the kite and forces it up. The string and the hand are to the kite what the weight of the flying creature is to the inclined planes formed by its wings.

Fig. 28.—Hawk and Pigeon.

The area of the insect, bird, and bat, when the wings are fully expanded, is greater than that of any other class of animals, their weight being proportionally less. As already stated, however, it ought never to be forgotten that even the lightest insect, bird, or bat is vastly heavier than the air, and that no fixed relation exists between the weight of body and expanse of wing in any of the orders. We have thus light-bodied and large-winged insects and birds, as the butterfly and heron; and others with heavy bodies and small wings, as the beetle and partridge. Similar remarks are to be made of bats. Those apparent inconsistencies in the dimensions of the body and wings are readily explained by the greater muscular development of the heavy-bodied, small-winged insects, birds, and bats, and the increased power and rapidity with which the wings in them are made to oscillate. This is of the utmost importance in the science of aërostation, as showing that flight may be attained by a heavy powerful animal with comparatively small wings, as well as by a lighter one with greatly enlarged wings. While, therefore, there is apparently no correspondence between the area of the wing and the animal to be raised, there is, unless in the case of sailing insects, birds, and bats, an unvarying relation as to the weight and number of oscillations; so that the problem of flight would seem to resolve itself into one of weight, power, velocity, and small surfaces, *versus* buoyancy, debility, diminished speed, and extensive surfaces,—weight in either case being a *sine qua non.*

That no fixed relation exists between the area of the wings and the size and weight of the body is evident on comparing the dimensions of the wings and bodies of the several orders of insects, bats, and birds. If such comparison be made, it will be found that the pinions in some instances diminish while the bodies increase, and the converse. No practical good can therefore accrue to aërostation from elaborate measurements of the wings and body of any flying thing; neither can any rule be laid down as to the extent of surface required for sustaining a given weight in the air. The statements here advanced are borne out by the fact that the wings of insects, bats, and birds may be materially reduced without impairing their powers of flight. In such cases the speed with which the wings are driven is increased in the direct ratio of the mutilation. The inference to be deduced from the foregoing is plainly this, that even in large-bodied, small-winged insects and birds the wing-surface is greatly in excess, the surplus wing area supplying that degree of elevating and sustaining power which is necessary to prevent undue exertion on the part of the volant animal. In this we have a partial explanation of the buoyancy of insects, and the great lifting power possessed by bats and birds,—the bats carrying their young without inconvenience, the birds elevating surprising quantities of fish, game, carrion, etc. (fig. 28)

While, as explained, no definite relation exists between the weight of a flying animal and the size of its flying surfaces, there being, as stated, heavy-bodied and small-winged insects, bats, and birds, and the converse, and while, as has been shown, flight is possible within a wide range, the wings being, as a rule, in excess of what are required for the purposes of flight,—still it appears from the researches of M. de Lucy that there is a general law, to the effect that the larger the volant animal the smaller by comparison are its flying surfaces. The existence of such a law is very encouraging so far as artificial flight is concerned, for it shows that the flying surfaces of a large, heavy, powerful flying machine will be comparatively small, and consequently comparatively compact and strong. This is a point of very considerable importance, as the object desiderated in a flying machine is elevating capacity.

M. de Lucy has tabulated his results as under:—

Insects.				Birds.			
Names.	Flying Surface referred to the Kilogramme = 2 lb. 8 oz. 3 dwt. 2 gr. avoird. = 2 lb. 3 oz. 4·428 dr. troy.			Names.	Flying Surface referred to the Kilogramme.		
	sq. yds.	ft.	in.		sq. yds.	ft.	in.
Gnat	11	8	92	Swallow	1	1	104½
Dragon-fly (small)	7	2	56	Sparrow	0	5	142½
Coccinella (Lady-bird)	5	13	87	Turtle dove	0	4	100½
Dragon-fly (common)	5	2	89	Pigeon	0	2	113
Tipula, or Daddy-long-legs	3	5	11	Stork	0	2	20
Bee	1	2	74½	Vulture	0	1	116
Meat-fly	1	3	54½	Crane of Australia	0	0	130
Drone (blue)	1	2	20				
Cockchafer	1	2	50				
Lucanus cervus: Stag-beetle (female)	1	1	39½				
Lucanus cervus: Stag-beetle (male)	0	8	33				
Rhinoceros-beetle	0	6	122½				

"It is easy, by the aid of this table, to follow the order, always decreasing, of the surfaces, in proportion as the winged animal increases in size and weight. Thus, in comparing the insects with one another, we find that the gnat, which weighs 460 times less than the stag-beetle, has 14 times more of surface. The lady-bird weighs 150 times less than the stag-beetle, and possesses 5 times more of surface, etc. It is the same with the birds. The sparrow weighs about 10 times less than the pigeon, and has twice as much surface. The pigeon weighs about 8 times less than the stork, and has twice as much surface. The sparrow weighs 339 times less than the Australian crane, and possesses 7 times more surface, etc. If now we compare the insects and the birds, the gradation will become even much more striking. The gnat, for example, weighs 97,000 times less than the pigeon, and has 40 times more surface; it weighs three millions of times less than the crane of Australia, and possesses 140 times more of surface than this latter, the weight of which is about 9 kilogrammes 500 grammes (25 lb. 5 oz. 9 dwt. troy, 20 lb. 15 oz. 2¼ dr. avoirdupois).

---

[1] The wings of the albatross, when fully extended, measure some 14 feet. They are exceedingly narrow, being sometimes under a foot in width.

The Australian crane, the heaviest bird weighed, is that which has the smallest amount of surface, for, referred to the kilogramme, it does not give us a surface of more than 899 square centimetres (139 square inches), that is to say, about an eleventh part of a square metre. But every one knows that these grallatorial animals are excellent birds of flight. Of all travelling birds they undertake the longest and most remote journeys. They are, in addition, the eagle excepted, the birds which elevate themselves the highest, and the flight of which is the longest maintained."[1]

The way in which the natural wing rises and falls on the air, and reciprocates with the body of the flying creature, has a very obvious bearing upon artificial flight. In natural flight the body of the flying creature falls slightly forward in a curve when the wing ascends, and is slightly elevated in a curve when the wing descends. The wing and body are consequently always playing at cross purposes, the wing rising when the body is falling and *vice versâ*. The alternate rise and fall of the body and wing of the bird are well seen when contemplating the flight of the gull from the stern of a steamboat, as the bird is following in the wake of the vessel. The complementary movements referred to are indicated at fig. 29, where the continuous waved line represents the trajectory made by the wing, and the dotted waved line that made by the body. As will be seen from this figure, *the wing advances both when it rises and when it falls.* It is a condition of natural wings, and of artificial wings constructed on the principle of living wings, that when forcibly elevated or depressed, even in a strictly vertical direction, they inevitably dart forward. If, for instance, the wing is suddenly depressed in a vertical direction, as at *a b* of fig. 29, it at once darts downwards and forwards (see continuous line of figure) to *c*, thus converting the vertical down stroke into a *down, oblique, forward stroke.* If, again, the wing be suddenly elevated in a strictly vertical direction, as at *c d*, the wing as certainly darts upwards and forwards in a curve to *e*, thus converting the vertical up strokes into an *upward, oblique, forward stroke.* The same thing happens when the wing is depressed from *e* to *f* and elevated from *g* to *h*, the wing describing a *waved track* as at *e g, g i*.

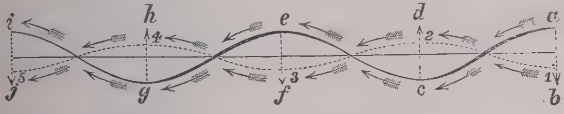

FIG. 29 shows how in progressive flight the wing and the body describe *waved tracks*,—the crests of the waves made by the wing (*a, c, e, g, i*) being placed opposite the crests of the waves made by the body (1, 2, 3, 4, 5). (Pettigrew, 1870.)

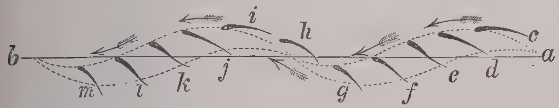

FIG. 30 shows the kite-like action of the wing during the down and up strokes, how the angles made by the wing with the horizon (*a, b*) vary at every stage of these strokes, and how the wing evades the superimposed air during the up stroke, and seizes the nether air during the down stroke. In this figure the spaces between the double dotted lines (*a g, i b*) represent the down strokes, the single dotted line (*h, i*) representing the up stroke. The kite-like surfaces and angles made by the wing with the horizon (*a, b*) during the down strokes are indicated at *c d e f g, j k l m*,—those made during the up strokes being indicated at *g h i*. As the down and up strokes run into each other, and the convex surface of the wing is always directed upwards and the concave surface downwards, it follows that the upper surface of the wing evades in a great measure the upper air, while the under surface seizes the nether air. It is easy to understand from this figure how the wing always flying forwards furnishes a persistent buoyancy. (Pettigrew, 1870.)

There are good reasons why the wings should always be in advance of the body. A bird when flying is a body in motion; but a body in motion tends to fall not vertically downwards, but *downwards and forwards.* The wings consequently must be in advance of the body of the bird if they are to prevent the bird from falling *downwards and forwards.* If the wings were to strike backwards in aërial flight, the bird would turn a forward somersault.

That the wings invariably strike downwards and forwards in aërial flight is proved alike by observation and experiment. If any one watches a bird rising from the ground or the water, he cannot fail to perceive that the head and body are slightly tilted upwards, and that the wings are made to descend with great vigor in a downward and forward direction. The dead natural wing and a properly constructed artificial wing act in precisely the same way. If the wing of a gannet, just shot, be removed and made to flap in what the operator believes to be a strictly vertical downward direction, the tip of the wing, in spite of him, will dart forwards between two and three feet—the amount of forward movement being regulated by the rapidity of the down stroke. This is a very striking experiment. The same thing happens with a properly constructed artificial wing. The down stroke with the artificial as with the natural wing is invariably converted into an oblique, downward, and forward stroke. No one ever saw a bird in the air flapping its wings towards its tail. The old idea was that the wings *pushed* the body of the bird in an upward and forward direction; in reality the wings do not push, but *pull*, and in order to pull they must always be in advance of the body to be flown. If the wings did not themselves fly *forward*, they could not possibly cause the body of the bird to fly forward. It is the wings which fly the bird, and not the converse.

It only remains to be stated that the wing acts as a true kite, during both down and up strokes, its under concave or biting surface, in virtue of the forward travel communicated to it by the body of the flying creature, being closely applied to the air, during both its ascent and its descent. This explains how the wing furnishes a persistent buoyancy alike when it rises and when it falls (fig. 30).

The natural kite formed by the wing differs from the artificial kite only in this, that the former is capable of being moved in all its parts, and is more or less flexible and elastic, whereas the latter is comparatively rigid. The flexibility and elasticity of the kite formed by the natural wing are rendered necessary by the fact that the wing, as already stated, is practically hinged at its root and along its anterior margin—an arrangement which necessitates its several parts travelling at different degrees of speed, in proportion as they are removed from the axes of rotation. Thus the tip travels at a higher speed than the root, and the posterior margin than the anterior margin. This begets a *twisting diagonal movement* of the wing on its long axis, which, but for the elasticity referred to, would break the wing into fragments. The elasticity contributes also to the continuous play of the wing, and insures that no two parts of it shall reverse at exactly the same instant. If the wing was inelastic, every part of it would reverse at precisely the same moment, and its vibration would be characterized by pauses or dead points at the end of the down and up strokes which would be fatal to it as a flying organ. The elastic properties of the wing are absolutely essential, when the mechanism and movements of the pinion are taken into account. A rigid wing can never be an effective flying instrument.

The kite-like surfaces referred to in natural flight are those upon which the constructors of flying machines very properly ground their hopes of ultimate success. These surfaces may be conferred on artificial wings, aëroplanes, aërial screws, or similar structures; and these structures, if we may judge from what we find in nature, *should be of moderate size and elastic.* The power of the flying organs will be increased if they are driven at a comparatively high speed, and particularly if they are made to reverse and reciprocate, as in this case they will practically create the currents upon which they are destined to rise and advance. The angles made by the kite-like surfaces with the horizon should vary according to circumstances. They should be small when the speed is high, and *vice versâ*. This, as stated, is true of natural wings. It should also be true of artificial wings and their analogues. There is no escaping from natural laws. A knowledge of natural laws alone will enable us to construct (it is to be hoped in the immediate future) the much-desired flying machine.

Having explained as far as space would permit how water differs from air, how the sailing ship differs from the balloon, and how the balloon differs from the flying creature and flying machine constructed on the living type, and having further explained the peculiarities of wings and wing movements as witnessed in natural flight, we are now in a position to enter upon a consideration of artificial wings and wing movements, and of artificial flight and flying machines.

---

[1] *On the Flight of Birds, of Bats, and of Insects, in reference to the subject of Aërial Locomotion*, by M. de Lucy, Paris.

We begin with artificial wings. The first properly authenticated account of an artificial wing was given by Borelli in 1670. This author, distinguished alike as a physiologist, mathematician, and mechanician, describes and figures a bird with artificial wings, each of which consists of *a rigid rod in front and flexible feathers behind.* The wings are represented as striking *vertically downwards,* as the annexed duplicate of Borelli's figure shows (fig. 31).

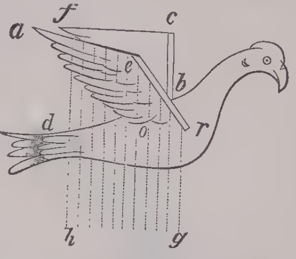

Fig. 31.—Borelli's bird with artificial wings. *r e*, anterior margin of the right wing, consisting of a rigid rod; *o a*, posterior margin of the right wing, consisting of flexible feathers; *b c*, anterior, and *f*, posterior margins of the left wing same as the right; *d*, tail of the bird; *r g*, *d h*, vertical direction of the down stroke of the wing. (Borelli, 1670.)

Borelli was of opinion that flight resulted from the application of an inclined plane, which beats the air, and which has a wedge action. He, in fact, endeavors to prove that a bird wedges itself forward upon the air by the perpendicular vibration of its wings, the wings during their action forming a wedge, the base of which (*c b e*) is directed towards the head of the bird, the apex (*a f*) being directed towards the tail (*d*). In the 196th proposition of his work (*De motu Animalium,* Leyden, 1685) he states that—

> "If the expanded wings of a bird suspended in the air shall strike the undisturbed air beneath it with a motion *perpendicular to the horizon,* the bird will fly with *a transverse motion* in a plane parallel with the horizon." "If," he adds, "the wings of the bird be expanded, and the under surfaces of the wings be struck by the air *ascending perpendicularly to the horizon* with such a force as shall prevent the bird gliding downwards (*i. e.,* with a tendency to glide downwards) from falling, it will be urged in a horizontal direction."
>
> The same argument is re-stated in different words as under:—"If the air under the wings be struck by the flexible portions of the wings (*flabella,* literally fly flaps or small fans) with a motion perpendicular to the horizon, the sails (*vela*) and flexible portions of the wings (*flabella*) will yield in an upward direction and form a wedge, the point of which is directed towards the tail. Whether, therefore, the air strikes the wings from below, or the wings strike the air from above, the result is the same,—the posterior or flexible margins of the wings *yield in an upward direction,* and in so doing urge the bird in *a horizontal direction.*"

There are three points in Borelli's argument to which it is necessary to draw attention:—(1) the direction of the down stroke: it is stated to be *vertically downwards;* (2) the construction of the anterior margin of the wing: it is stated to consist of *a rigid rod;* (3) the function delegated to the posterior margin of the wing: it is said *to yield in an upward direction* during the down stroke.

With regard to the first point. It is incorrect to say the wing strikes *vertically downwards,* for, as already explained, the body of a flying bird is a body in motion; but as a body in motion tends to fall downwards and forwards, the wing must strike *downwards* and *forwards* in order effectually to prevent its fall. Moreover, in point of fact, all natural wings and all artificial wings constructed on the natural type invariably strike *downwards and forwards.*

With regard to the second point, viz., the supposed *rigidity* of the anterior margin of the wing, it is only necessary to examine the anterior margins of natural wings to be convinced that they are in every case *flexible and elastic.* Similar remarks apply to properly constructed artificial wings. If the anterior margins of natural and artificial wings were rigid, it would be impossible to make them vibrate smoothly and continuously. This is a matter of experiment. If a rigid rod, or a wing with a rigid anterior margin, be made to vibrate, the vibration is characterized by an unequal jerky motion, which contrasts strangely with the smooth, steady, fanning movement peculiar to natural wings.

As to the third point, viz., *the upward bending of the posterior margin of the wing during the down stroke,* it is necessary to remark that the statement is true if it means a slight upward bending, but that it is untrue if it means an extensive upward bending.

Borelli does not state the amount of upward bending, but one of his followers, Professor E. J. Marey, maintains that during the down stroke the wing yields until its under surface makes *a backward angle with the horizon of 45°.* Marey further states that during the up stroke the wing yields to a corresponding extent in an opposite direction—the posterior margin of the wing, according to him, passing through an angle of 90°, plus or minus, according to circumstances, every time the wing rises and falls.

That the posterior margin of the wing yields to a slight extent during both the down and up strokes will readily be admitted alike because of the very delicate and highly elastic properties of the posterior margins of wings, and because of the comparatively great force employed in their propulsion; but that they do not yield to the extent stated by Professor Marey is a matter of absolute certainty. This admits of direct proof. If any one watches the horizontal or upward flight of a large bird he will observe that the posterior or flexible margin of the wing never rises during the down stroke to a perceptible extent, so that the under surface of the wing never looks backwards. On the contrary, he will perceive that the under surface of the wing (during the down stroke) invariably looks forwards and forms a true kite with the horizon, the angles made by the kite varying at every part of the down stroke, as shown more particularly at *c d e f g, i j k l m* of fig. 30, p. 277.

The authors who have adopted Borelli's plan of artificial wing, and who have endorsed his mechanical views of the wing's action most fully, are Chabrier, Straus-Durkheim, Girard, and Marey. Borelli's artificial wing, it will be remembered, consists of a *rigid rod* in front and a *flexible sail* behind. It is also made to strike *vertically downwards.* According to Chabrier, the wing has only one period of activity. He believes that if the wing be suddenly lowered by the depressor muscles, it is elevated solely by the reaction of the air. There is one unanswerable objection to this theory: the bats and birds, and some if not all the insects, have distinct elevator muscles, and can elevate their wings at pleasure when not flying and when consequently the reaction of the air is not elicited. Straus-Durkheim agrees with Borelli both as to the natural and the artificial wing. Durkheim is of opinion that the insect abstracts from the air by means of the *inclined plane* a component force (*composant*) which it employs to *support* and *direct* itself. In his theology of nature he describes a schematic wing as consisting of a *rigid ribbing* in front, and a *flexible sail* behind. A membrane so constructed will, according to him, be fit for flight. It will suffice if such a sail elevates and lowers itself successively. It will of its own accord dispose itself as an inclined plane, and *receiving obliquely the reaction of the air,* it transfers into *tractile force* a part of the *vertical impulsion it has received.* These two parts of the wing, moreover, are equally indispensable to each other.

Marey repeats Borelli and Durkheim with very trifling modifications, so late as 1869.[1] He describes two artificial wings, the one composed of a *rigid rod* and *sail*—the rod representing *the stiff anterior margin* of the wing; the sail, which is made of paper bordered with card board, *the flexible posterior margin.* The other wing consists of a *rigid nervure* in front and behind of thin parchment which supports fine rods of steel. He states that, if the wing only elevates and depresses itself, "the *resistance of the air* is sufficient to produce all the other movements. In effect (according to Marey) the wing of an insect has not the power of equal resistance in every part. On the anterior margin the extended nervures make it *rigid,* while behind it is fine and *flexible.* During the vigorous depression of the wing, the nervure has the power of *remaining rigid,* whereas the flexible portion, *being pushed in an upward direction* on account of the resistance it experiences from the air, assumes an oblique position which causes *the upper surface of the wing to look forwards.*" The reverse of this in Marey's opinion, takes place during the elevation of the wing—the resistance of the air from above causing *the upper surface of the wing to look backwards*. . . . "At first," he says, "the plane of the wing is parallel with the body of the animal. It lowers itself—*the front part of the wing strongly resists*, the sail which follows it being flexible *yields*. Carried by the ribbing (the anterior margin of the wing) which lowers itself, *the sail or posterior margin of the wing being raised meanwhile by the air*, which sets it straight again, the sail will take an intermediate position and *incline itself about 45° plus or minus* according to circumstances. . . . The wing continues its movements of depression inclined to the horizon; but the impulse of the air, which continues its effect, and naturally acts upon the surface which it strikes, has the power of resolving itself into two forces, *a vertical* and a *horizontal* force; the first suffices *to raise* the animal, the second *to move it along*."[1] Professor Marey, it will be observed, reproduces Borelli's artificial wing, and even his text, at a distance of nearly two centuries.

[1] *Revue des Cours Scientifiques de la France et de l'Étranger,* 1869, par M. le Docteur Marey, professeur au Collége de France.

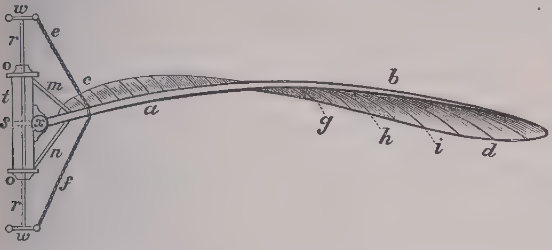

FIG. 32.—Elastic spiral wing, which twists and untwists during its action, to form *a mobile helix or screw*. This wing is made to vibrate by a direct piston action, and by a slight adjustment can be propelled vertically, horizontally, or at any degree of obliquity.

a b, Anterior margin of wing, to which the neuræ or ribs are affixed. *c d*, Posterior margin of wing crossing anterior one. *x*, Ball-and-socket joint at root of wing, the wing being attached to the side of the cylinder by the socket. *t*, Cylinder. *r r*, Piston, with cross heads (*w*, *w*) and piston head (*s*). *o o*, Stuffing boxes. *e*, *f*, Driving chains. *m*, Superior elastic band, which assists in elevating the wing. *n*, Inferior elastic band, which antagonizes *m*. The alternate stretching of the superior and inferior elastic bands contributes to the continuous play of the wing, by preventing dead points at the end of the down and up strokes. The wing is free to move in a vertical and horizontal direction and at any degree of obliquity. (Pettigrew, 1870.)

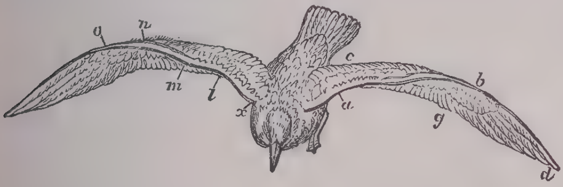

FIG. 33 shows the spiral elastic wings of the Gull. Each wing forms a mobile helix or screw. *a b*, Anterior margin of left wing; *c d*, posterior margin of ditto; *d g*, primary or rowing feathers of left wing; *g a*, secondary feathers ditto; *x*, root of right wing with ball-and-socket joint; *l*, elbow joint; *m*, wrist joint; *n*, *o*, hand and finger joints. (Pettigrew, 1870.)

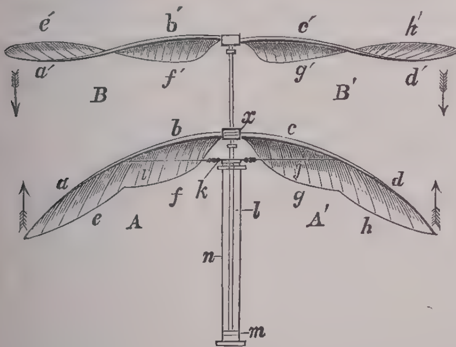

FIG. 34.—Double elastic wing driven by direct piston action. During the up stroke of the piston the wing is very decidedly convex on its upper surface (*a b c d*, A A′); its under surface (*e f g h*, A A′) being deeply concave and inclined obliquely upwards and forwards. It thus evades, to a considerable extent, the air during the up stroke. During the down stroke of the piston the wing is flattened out in every direction, and its extremities twisted in such a manner as to form two screws, as seen at *a′ b′ c′ d′*, *e′ f′ g′ h′*, B, B′. The active area of the wing is by this arrangement considerably diminished during the up stroke, and considerably augmented during the down stroke; the wing seizing the air with greater avidity during the down than during the up stroke. *i*, *j*, *k*, elastic band to regulate the expansion of the wing; *l*, piston; *m*, piston head; *n*, cylinder. (Pettigrew, 1870.)

The artificial wing recommended by Professor Pettigrew is a more exact imitation of nature than either of the foregoing. It is of a more or less triangular form, thick at the root and anterior margin, and thin at the tip and posterior margin. *No part of it is rigid.* It is on the contrary highly elastic and flexible throughout. It is furnished with springs at its root to contribute to its continued play, and is applied to the air by a direct piston action in such a way that it descends in a downward and forward direction during the down stroke, and ascends in an upward and forward direction during the up stroke. It elevates and propels both when it rises and falls. *It, moreover, twists and untwists during its action and describes figure-of-8 and waved tracks in space, precisely as the natural wing does.* The twisting is most marked at the tip and posterior margin, particularly that half of the posterior margin next the tip. The wing when in action may be divided into two portions by a line running diagonally between the tip of the wing anteriorly and the root of the wing posteriorly. The tip and posterior parts of the wing are more active than the root and anterior parts, from the fact that the tip and posterior parts (the wing is an eccentric) always travel through greater spaces, in a given time, than the root and anterior parts.

The wing is so constructed that the posterior margin yields freely in a downward direction during the up stroke, while it yields comparatively little in an upward direction during the down stroke; and this is a distinguishing feature, as the wing is thus made to fold and elude the air more or less completely during the up stroke, whereas it is made to expand and seize the air with avidity during the down stroke. The oblique line referred to as running diagonally across the wing virtually divides the wing into an active and a passive part, the former elevating and propelling, the latter sustaining.

It is not possible to determine with exactitude the precise function discharged by each part of the wing, but experiment tends to show that the tip of the wing *elevates*, the posterior margin *propels*, and the root *sustains*.

The wing—and this is important—is driven by a direct piston action with an irregular hammer-like movement, the pinion having communicated to it a smart click at the beginning of every down stroke—the up stroke being more uniform. The arrangement is that shown in fig. 32. If the artificial wing here represented (fig. 32) be compared with the natural wing as depicted at fig. 33, it will be seen that there is nothing in the one which is not virtually reproduced in the other. In addition to the foregoing, Professor Pettigrew recommends a double elastic wing to be applied to the air like a steam-hammer, by being fixed to the head of the piston. This wing, like the single wing described, twists and untwists as it rises and falls, and possesses all the characteristics of the natural wing (fig. 34).

He also recommends an *elastic aërial screw* consisting of two blades, which taper and become thinner towards the tips and posterior margins. When the screw is made to rotate, the blades, because of their elasticity, assume a great variety of angles, the angles being least where the speed of the blades is greatest and *vice versâ*. The pitch of the blades is thus regulated by the speed attained (fig. 35).

The peculiarity of Professor Pettigrew's wings and screws consists in their *elasticity*, their *twisting action*, and their *great comparative length and narrowness*. They offer little resistance to the air when they are at rest, and when in motion the speed with which they are driven is such as to ensure that the comparatively large spaces through which they travel shall practically be converted into solid bases of support.

Since Professor Pettigrew enunciated his views (1867) as to the screw configuration and elastic properties of natural wings, and more especially since his introduction of *spiral, elastic artificial wings, and elastic screws*, a great revolution has taken place in the construction of flying models. Elastic aëro-planes are now advocated by Mr. Brown,[1] elastic aerial screws by Mr. Armour,[2] and elastic aëro-planes, wings, and screws by M. Pénaud.[3]

---

[1] Professor E. J. Marey, *op. cit.*, 1869.

M. Pénaud's experiments are alike interesting and instructive. He constructed models to fly by three different methods:—(*a*) by means of screws acting vertically upwards; (*b*) by aëro-planes propelled horizontally by screws; and (*c*) by wings which flapped in an upward and downward direction. An account of his helicoptère or screw model appears in the *Aëronaut* for January, 1872, but before giving a description of it, it may be well to state very briefly what is known regarding the history of the screw as applied to the air.

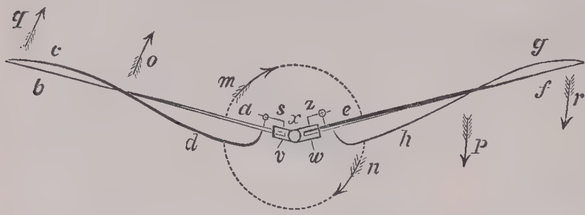

FIG. 35.—Elastic aërial screw with twisted blades resembling wings (*a b c d, e f g h*); *x*, end of driving shaft; *v, w*, sockets in which the roots of the blades of the screw rotate, the degree of rotation being limited by steel springs (*z, s*); *a b, e f*, tapering elastic rods forming anterior or thick margins of blades of screw; *d c, h g*, posterior or thin elastic margins of blades of screw. The arrows *m, n, o, p, q, r* indicate the direction of travel. (Pettigrew, 1870.)

The first suggestion on this subject was given by Paucton in 1768. This author, in his treatise on the *Théorie de la Vis d'Archiméde*, describes a machine provided with two screws which he calls a "ptérophores." In 1796 Sir George Cayley gave a practical illustration of the efficacy of the screw as applied to the air by constructing a small machine, consisting of two screws made of quill feathers, a representation of which we annex (fig. 36). Sir George writes as under:—

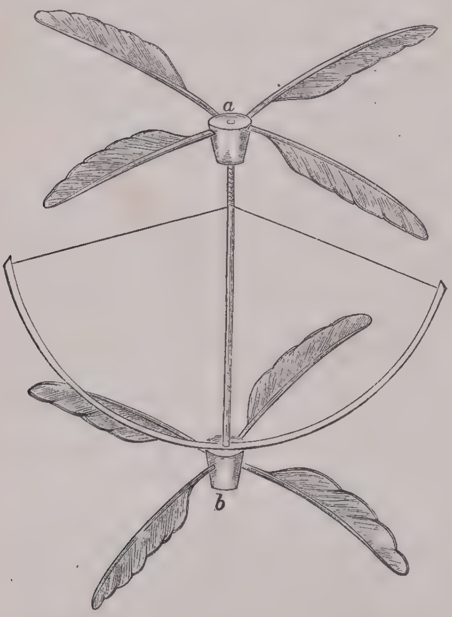

FIG. 36.—Cayley's Flying Model (1796).

> "As it may be an amusement to some of your readers to see a machine rise in the air by mechanical means, I will conclude my present communication by describing an instrument of this kind, which any one can construct at the expense of ten minutes' labor.
>
> "*a* and *b*, fig. 36, are two corks, into each of which are inserted four wing feathers from any bird, so as to be slightly inclined like the sails of a windmill, but in opposite directions in each set. A round shaft is fixed in the cork *a*, which ends in a sharp point. At the upper part of the cork *b* is fixed a whalebone bow, having a small pivot hole in its centre to receive the point of the shaft. The bow is then to be strung equally on each side to the upper portion of the shaft, and the little machine is completed. Wind up the string by turning the flyers different ways, so that the spring of the bow may unwind them with their anterior edges ascending; then place the cork with the bow attached to it upon a table, and with a finger on the upper cork press strong enough to prevent the string from unwinding, and, taking it away suddenly, the instrument will rise to the ceiling."

Cayley's screws were peculiar, inasmuch as they were superimposed and rotated in opposite directions. He estimated that if the area of the screws was increased to 200 square feet, and moved by a man, they would elevate him. His interesting experiment is described at length, and the apparatus figured, in *Nicolson's Journal*, 1809, p. 172.

Other experimenters followed Cayley at moderate intervals:—Deghen in 1816, Ottoris Sarti in 1823, and Dubochet in 1834. These inventors all constructed flying models on the vertical screw principle. In 1842 Mr. Philips succeeded in elevating a steam model by the aid of revolving fans, which flew across two fields after having attained a great altitude; and in 1859 Mr. Bright took out a patent for a machine to be sustained by vertical screws, the model of which is to be seen at the patent museum, Kensington, London. In 1863 the subject of aviation by vertical screws received a fresh impulse from the experiments of MM. Ponton d'Amécourt, De la Landelle, and Nadar, who exhibited models driven by clock-work springs, which ascended with graduated weights a distance of from 10 to 12 feet. These models were so fragile that they usually broke in coming in contact with the ground in their descent. Their flight, moreover, was unsatisfactory, from the fact that it only lasted a few seconds.

Stimulated by the success of his spring models, M. Ponton d'Amécourt had a small steam model constructed. This model, which was shown at the exhibition of the Aëronautical Society of Great Britain at the Crystal Palace in 1868, consisted of two superposed screws propelled by an engine, the steam for which was generated (for lightness) in an aluminium boiler. This steam model proved a failure, inasmuch as it only lifted a third of its own weight.

Fig. 37 embodies M. de la Landelle's ideas.

All the models referred to (Cayley's excepted[4]) were provided with *rigid* screws, which, for many reasons, we are disposed to regard as an error. In 1872 M. Pénaud discarded the rigid screws in favor of elastic ones, as Professor Pettigrew had done some years before.

M. Pénaud also substituted india-rubber under torsion for the whalebone and clock springs of the smaller models, and the steam of the larger ones. His helicoptère or screw model is remarkable for its lightness, simplicity, and power The accompanying sketch will serve to illustrate its construction (fig. 38). It consists of two superposed elastic screws (*a a, b b*), the upper of which (*a a*) is fixed in a vertical frame (*c*), which is pivoted in the central part (*d*) of the under screw. From the centre of the under screw an axle provided with a hook (*e*), which performs the part of a crank, projects in an upward direction. Between the hook or crank (*e*) and the centre of the upper screw (*a a*), the india-rubber in a state of torsion (*f*) extends. By fixing the lower screw and turning the upper one a sufficient number of times the requisite degree of torsion and power is obtained. The apparatus when liberated flies into the air sometimes to a height of 50 feet, and gyrates in beautiful large circles for a period varying from 15 to 30 seconds.

M. Pénaud next directed his attention to the construction of a model, to be propelled by a screw and sustained by an elastic aëro-plane extending horizontally. Sir George Cayley, it should be stated, proposed such a machine in 1810, and Mr. Henson (as will be shown subsequently) constructed and patented a similar machine in 1842.

[2] "Resistance to Falling Planes on a Path of Translation," *Ninth Annual Report of the Aëronautical Society of Great Britain*, 1874.

[3] The *Aëronaut* for January, 1872, and February, 1875.

[4] Cayley's screws, as explained, were made of feathers, and consequently elastic. As, however, no allusion is made in his writings to the superior advantages possessed by elastic over rigid screws, it is to be presumed that feathers were employed simply for convenience and lightness. Professor Pettigrew, there is reason to believe, was the first to advocate the employment of elastic screws for aërial purposes.

Several other inventors succeeded in making models fly by the aid of aëro-planes and screws, as *e.g.*, Mr. Stringfellow in 1847,[1] M. du Temple in 1857, and M. Jullien in 1858. As *rigid* aëro-planes and screws were employed in the construction of these models they flew in a hap-hazard sort of a way, it being found exceedingly difficult to confer on them the necessary degree of stability fore and aft and laterally. M. Pénaud succeeded in overcoming the difficulty in question by the invention of what he designates his automatic rudder. This consists of a small *elastic* aëro-plane placed aft or behind the principal aëro-plane, which is also *elastic*. The two elastic aëro-planes extend horizontally and make a slight upward angle with the horizon, the angle made by the smaller aëro-plane (the rudder) being slightly in excess of that made by the larger. The motive power is india-rubber in the condition of torsion; the propeller, a screw. The reader will understand the arrangement by reference to the accompanying drawing (fig. 39).

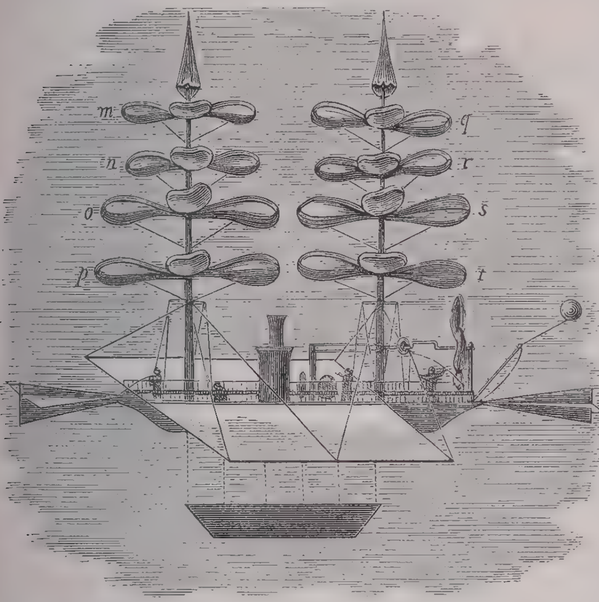

Fig. 37.—*m, n, o, p*; *q, r, s, t*, screws arranged on vertical axes to act vertically upwards. The vertical axes are surmounted by two parachutes, and the body of the machine is furnished with an engine, propeller, rudders, and an extensive aëro-plane. (M. de la Landelle, 1863.)

Models on the aëro-plane screw type may be propelled by two screws, one fore and one aft, rotating in opposite directions; and in the event of only one screw being employed it may be placed in front of or behind the aëro-plane.

When the model is wound up and let go it descends about two feet, after which, having acquired initial velocity, it rises and flies in a forward direction at a height of from 8 to 10 feet from the ground for a distance of from 120 to 130 feet. It flies this distance in from 10 to 11 seconds, its mean speed being something like 12 feet per second. From experiments made with this model, M. Pénaud calculates that one horse power would elevate and support 85 ℔.

Mr. Brown has also written (1874) in support of elastic aëro-bi-planes. His experiments prove that two elastic aëro-planes united by a central shaft or shafts, and separated by a wide interval, always produce increased stability. The production of flight by the vertical flapping of wings is in some respects the most difficult, but this also has been attempted and achieved. M. Pénaud and M. de Villeneuve have each constructed winged models. Professor Marey was not so fortunate. He endeavored to construct an artificial insect on the plan advocated by Borelli, Straus-Durkheim, and Chabrier, but signally failed, his insect never having been able to lift more than a third of its own weight.

MM. de Villeneuve and Pénaud constructed their winged models on different types, the former selecting the bat, the latter the bird. M. Villeneuve made the wings of his artificial bat conical in shape and comparatively rigid. He controlled the movements of the wings, and made them strike downwards and *forwards* in imitation of natural wings, as described by Professor Pettigrew. His model possessed great power of rising. It elevated itself from the ground with ease, and flew in a horizontal direction for a distance of 24 feet, and at a velocity of 20 miles an hour. M. Pénaud's model differed from M. de Villeneuve's in being provided with elastic wings, the posterior margins of which in addition to being elastic were free to move round the anterior margins as round axes (see p. 274, fig. 24). India-rubber springs were made to extend between the inner posterior parts of the wings and the frame, corresponding to the backbone of the bird.

A vertical movement having been communicated by means of india-rubber in a state of torsion to the roots of the wings, the wings themselves, in virtue of their elasticity, and because of the resistance experienced from the air, twisted and untwisted and formed reciprocating screws, precisely analogous to those originally described and figured by Professor Pettigrew in 1867. M. Pénaud's arrangement is shown in fig. 40.

If the left wing of M. Pénaud's model (*a b*, *c d* of fig. 40) be compared with the wing of the bat as drawn by Professor Pettigrew (fig. 18, page 273), or with Professor Pettigrew's artificial wing (page 279, fig. 32), the identity of principle and application is at once apparent.

The twisting kite-like action of the wings, to which allusion has so frequently been made, and to which, as has been shown, Professor Pettigrew first strongly directed attention in 1867, justifies our introductory remarks as to the very intimate relation which subsists between natural and artificial flight. As already stated, it is not possible to understand artificial flight in the absence of a knowledge of natural flight.

In M. Pénaud's artificial bird the equilibrium is secured by the addition of a tail. The model cannot raise itself from the ground, but on being liberated from the hand it descends 2 feet or so, when, having acquired initial velocity, it flies horizontally for a distance of 50 or more feet, and rises as it flies from 7 to 9 feet. The following are the measurements of the model in question:—length of wing from tip to tip, 32 inches; weight of wing, tail, frame, india-rubber, etc., 73 grammes (about 2½ ounces).

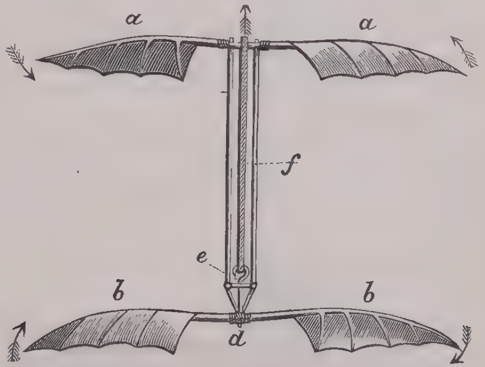

Fig. 38.—Helicoptère or Screw-Model, by M. Pénaud. (1872.)

We have referred to Mr. Henson's flying machine, which was designed in 1843. As it was the earliest attempt at aërostation on a great scale it deserves a more than passing notice. Mr. Henson was one of the first to combine aërial screws with extensive supporting structures occupying a nearly horizontal position. The accompanying illustration explains the combination (fig. 41).

---

[1] Mr. Stringfellow constructed a second model, which was exhibited at the exhibition of the Aëronautical Society (Crystal Palace), in 1868. It is described and figured further on.

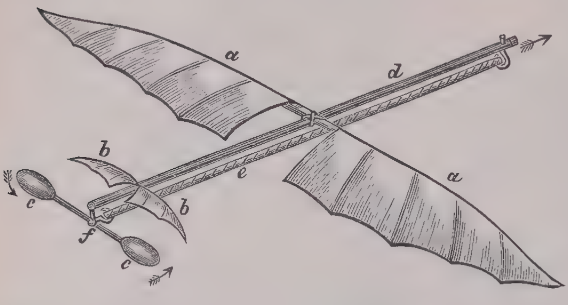

Fig. 39.—Aëro-plane model with automatic rudder. *a a*, elastic aëro-plane; *b*, *b*, automatic rudder; *c c*, aërial screw centred at *f*; *d*, frame supporting aëro-plane, rudder, and screw; *e*, india-rubber, in a state of torsion, attached to hook or crank at *f*. By holding the aëro-plane (*a a*) and turning the screw (*c c*) the necessary power is obtained by torsion. (M. Pénaud, 1872.)

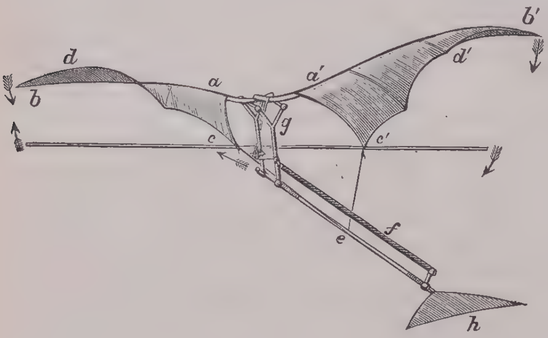

Fig. 40.—Artificial flying bird. *a b c d*, *a' b' c' d'*, elastic wings, which twist and untwist when made to vibrate; *a b*, *a' b'*, anterior margins of wings; *c d*, *c' d'*, posterior margins of wings; *c*, *c'*, inner portions of wings attached to central shaft of model by elastic bands at *e*; *f*, india-rubber in a state of torsion, which provides motive power, by causing the crank situated between the vertical wing supports (*g*) to rotate; as the crank revolves the wings are made to vibrate by means of two rods which extend between the crank and the roots of the wings; *h*, tail of artificial bird. (M. Pénaud, 1872.)

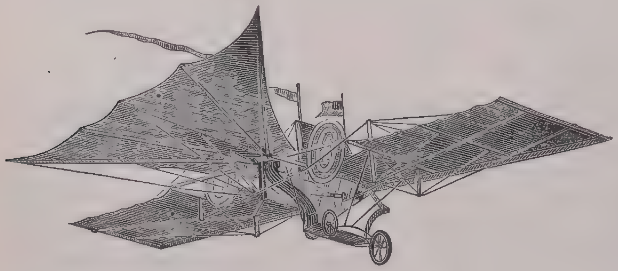

Fig. 41.—Henson's Aërostat (1843).

"The chief feature of the invention was the very great expanse of its sustaining planes, which were larger in proportion to the weight it had to carry than those of many birds. The machine advanced *with its front edge a little raised*, the effect of which was to present its under surface to the air over which it passed, the resistance of which, acting upon it like a strong wind on the sails of a windmill, prevented the descent of the machine and its burden. The sustaining of the whole, therefore, depended upon the speed at which it travelled through the air, and *the angle at which its under surface impinged on the air in its front*. . . . The machine, fully prepared for flight, was started from the top of an inclined plane, in descending which it attained a velocity necessary to sustain it in its further progress. That velocity would be gradually destroyed by the resistance of the air to the forward flight; it was therefore, the office of the steam-engine and the vanes it actuated simply to repair the loss of velocity; it was made, therefore, only of the power and weight necessary for that small effect." The editor of Newton's *Journal of Arts and Sciences* speaks of it thus:—"The apparatus consists of a car containing the goods, passengers, engines, fuel, etc., to which a rectangular frame, made of wood or bamboo cane, and covered with canvas or oiled silk, is attached. This frame extends on either side of the car in a similar manner to the outstretched wings of a bird; but with this difference, that *the frame is immovable*. Behind the wings are two vertical fan wheels, furnished with oblique vanes, which are intended to propel the apparatus through the air. The rainbow-like circular wheels are the propellers, answering to the wheels of a steam-boat, and acting upon the air after the manner of a windmill. These wheels receive motions from bands and pulleys from a steam or other engine contained in the car. To an axis at the stern of the car a triangular frame is attached, resembling the tail of a bird, which is also covered with canvas or oiled silk. This may be expanded or contracted at pleasure, and is moved up and down for the purpose of causing the machine to ascend or descend. Beneath the tail is a rudder for directing the course of the machine to the right or to the left; and to facilitate the steering a sail is stretched between two masts which rise from the car. The amount of canvas or oiled silk necessary for buoying up the machine is stated to be equal to one square foot for each half pound of weight."

The defect of Mr. Henson's machine consists mainly in its rigidity, and in the vast amount of sustaining surface displayed by it, this approximating it in some measure to the balloon.

Mr. Wenham, thinking to improve upon Mr. Henson, invented in 1867 what he designated his aëro-planes.[1] The aëro-planes are thin, light, long narrow structures, arranged above each other in tiers like so many shelves. They are tied together at a slight upward angle, and combine strength and lightness. The idea is to obtain great sustaining area in comparatively small space. It was hoped that when the aëro-planes were wedged forward in the air by vertical screws, or by the body to be flown, each aëro-plane would rest or float upon a stratum of undisturbed air, and that practically the aëro-planes would give the same support as if spread out horizontally. The aëro-planes may be said to form a compound kite, and have only been partially successful. They are rigid, and present a large extent of dead surface, so that the same objections made to Mr. Henson's arrangement apply to them. The great sustaining surface they present forms at once their strength and weakness. They sustain and lift, but are very difficult to wedge forward, and if a breeze be blowing they become unmanageable, in the sense that a balloon is unmanageable. The accompanying figures illustrate Mr. Wenham's views (figs. 42 and 43).

Mr. Stringfellow, who was originally associated with Mr. Henson, and constructed a successful flying model in 1847, built a second model in 1868, in which Mr. Wenham's aëro-planes were combined with aërial screws. This model was on view at the Exhibition of the Aëronautical Society of Great Britain, held at the Crystal Palace, London, in 1868. It was remarkably compact, elegant, and light, and obtained the £100 prize of the exhibition for its engine, which was the lightest and most powerful ever constructed. The annexed woodcut (fig. 44), taken from a photograph of Mr. Stringfellow's model, gives a very good idea of the arrangement,—*a*, *b*, *c* representing the superimposed planes, *d* the tail, *e*, *f* the vertical screw propellers. The superimposed planes (*a*, *b*, *c*) in this machine contained a sustaining area of 28 square feet, in addition to the tail (*d*). Its engine represented a third of a horse power, and the weight of the whole (engine, boiler, water, fuel, superimposed planes, and propellers) was under 12 lb. Its sustaining area, if that of the tail (*d*) be included, was something like 36 square feet, *i.e.*, 3 square feet for every pound. The model was forced by its propellers along a wire at a great speed, but so far as an observer could determine, failed to lift itself, notwithstanding its extreme lightness and the comparatively very great power employed. Mr. Stringfellow stated that his machine occasionally left the wire and was sustained by its aëro-planes alone. The horizontal speed attained was certainly very great; but as the machine was exhibited under cover in the Crystal Palace buildings, and ran along a wire, it is doubtful how it would have deported itself in the open air. Everything about it was *rigid*, the aëro-planes, screws, etc.; and as the dead surfaces displayed were comparatively very large, the chances are that it would not have been able to hold its own against air currents. That the principle of its construction was faulty is proved beyond doubt by the fact that it weighed under 12 ℔, while its engine exerted a third of a horse power. No flying creature, as is well known, weighing 12 ℔ possesses a tithe of the power indicated. This fact is significant as showing that flight is not a mere question of levity and power. As has been more than once stated in the present article, the mystery of flight can only be cleared up by an intelligent study of the structure and mode of application of the flying organs of animals. It is to natural flight and the principles which underlie it that the aëronaut must look for a solution of the intensely interesting but vastly complicated problem of aërial navigation.

---

[1] "On Aërial Locomotion," *Aëronautical Society's Report* for 1867.

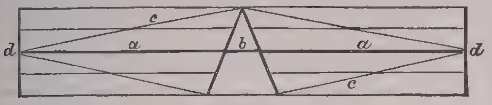

Fig. 42.

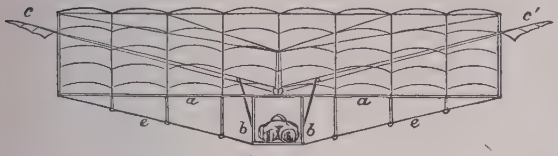

Fig. 43.

Fig. 42 represents a system of aëro-planes designed to carry a man. *a, a*, thin planks, tapering at each end, and attached to a triangle: *b*, similar plank for supporting the aëronaut; *c, c*, thin bands of iron which truss planks *a, a*; *d, d*, vertical rods. Between these are stretched five bands of holland 15 inches broad and 16 feet long, the total length of the web being 80 feet. This apparatus, when caught by a gust of wind, actually lifted the aëronaut. (Wenham, 1867.)

Fig. 43.—A system of aëro-planes similar to that represented at fig. 42. *a a*, main spar 16 feet long; *b b*, panels, with base board for aëronaut attached to main spar; *e e*, thin tie-band of steel with struts starting from main spar. This forms a strong light framework for the aëro-planes, consisting of six webs of thin holland 15 inches broad. The aëro-planes are kept in parallel plane by vertical divisions of holland 2 feet wide. *c, c*, wing propellers driven by the feet. (Wenham, 1867.)

The idea embodied by Henson, Wenham, and Stringfellow is plainly that of a boy's kite sailing upon the wind. The kite, however, is a more perfect flying apparatus than that furnished by these gentlemen, inasmuch as the inclined plane formed by its body strikes the air at various angles—the angles varying according to the length of string, strength of breeze, length and weight of tail, etc. Henson's, Wenham's, and Stringfellow's methods, although carefully tried, have hitherto failed. The objections are numerous. In the first place, the supporting planes (aëro-planes or other forms) are not flexible and elastic as wings are, but *rigid;* 2d, they strike the air *at a given angle*, where, again, there is a departure from nature; 3d, a machine so constructed must be precipitated from a height or driven along the surface of the land or water at a high speed to supply it with initial velocity; 4th, it is unfitted for flying with the wind unless its speed greatly exceeds that of the wind; 5th, it is unfitted for flying across the wind because of the large surfaces exposed; 6th, the sustaining surfaces are passive or dead surfaces, *i. e.*, they have no power of moving or accommodating themselves to altered circumstances. Natural wings, as explained, present small flying surfaces, and these can be applied to the air at any degree of obliquity—the great speed at which wings are propelled converting the spaces through which they pass into what are practically solid bases of support, as indicated at pp. 271, 274 (figs. 9, 20, 21, 22, and 23).

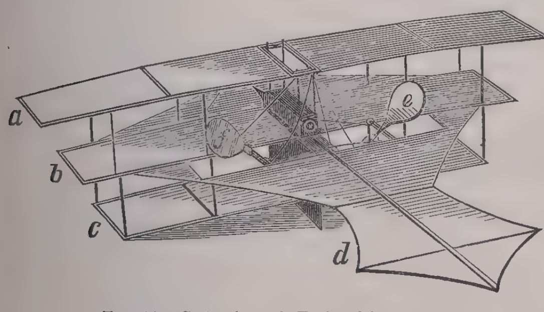

Fig. 44.—Stringfellow's Flying Machine (1868).

This arrangement enables natural wings to seize and utilize the air, and renders them superior to adventitious currents. Natural wings work up the air in which they move; but unless the volant animal desires it, they are scarcely, if at all, influenced by winds or currents which are not of their own forming. In this respect they differ entirely from the balloon and all forms of fixed aëro-planes. In nature small wings driven at a high speed produce the same result as large wings driven at a low speed. In flight a certain space must be covered, either by large wings spread out as solids, or by small wings made to vibrate rapidly. A like result is obtained if air currents travelling at a high speed strike the under surfaces of the wings of the volant animal. In the former cases the wings are active, the air passive; in the latter case the air is active and the wings passive.

It would be easy to multiply almost indefinitely our list of aërial models and flying machines.[1] As however the present article has already attained sufficiently large dimensions it will suffice if we refer in conclusion to the aërial steamer of Mr. Moy, designed in 1874, and still in process of construction. Its leading features will readily be understood by a reference to the annexed drawing (fig. 45).

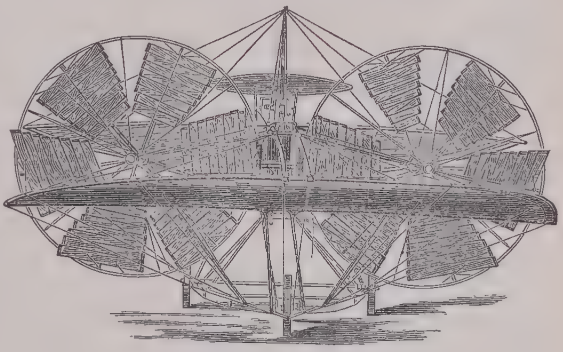

Fig. 45.—Moy's Aërial Steamer (1874).

Mr. Moy's invention consists of a light, powerful, skeleton frame resting on three wheels; a very effective light engine constructed on a new principle, which dispenses with the old-fashioned, cumbrous boiler; two long, narrow, horizontal aëro-planes; and two comparatively very large aërial screws. The idea is to get up the initial velocity by a preliminary run on the ground. This accomplished it is hoped that the weight of the machine will gradually be thrown upon the aëro-planes in the same way that the weight of certain birds—the eagle, *e.g.*—is thrown upon the wings after a few hops and leaps. Once in the air the aëro-planes will become effective in proportion to the speed attained. Mr. Moy's machine resembles in its general features that of Mr. Stringfellow. It repeats its defects as far as rigid surfaces are concerned, but it has the advantage in presenting a relatively less amount of surface. The diminished surface of Mr. Moy's machine is, moreover, more broken up, and what is important, a relatively greater proportion of the surface (so diminished and broken up) is made active or moving surface. These are hopeful features.

The unremitting efforts of Mr. Moy and other British engineers to construct flying machines deserve well of science. They are significant as showing that the great subject of aërial navigation is at length receiving a fair share of the thought and energy of a country which has already produced the steamboat and locomotive, and which, there is good reason to believe, is destined also to produce the flying machine. (J. B. P.)

---

[1] The most recent experiments in aërial transit are described in the *Transactions of the New Zealand Institute*, vol x., 1878.

FLINCK, GOVERT (1615–1660), born at Cleves in 1615, was apprenticed by his father to a silk mercer, but having secretly acquired a passion for drawing, was sent to Leuwarden, where he boarded in the house of Lambert Jacobszon, a Mennonite, better known as an itinerant preacher than as a painter. Here Flinck was joined by Jacob Backer, and the companionship of a youth determined like himself to be an artist only confirmed his passion for painting. Amongst the neighbors of Jacobszon at Leuwarden were the sons and relations of Rombert Ulenburg, whose daughter Saske married Rembrandt in 1634. Other members of the same family lived at Amsterdam, cultivating the arts either professionally or as amateurs. The pupils of Lambert probably gained some knowledge of Rembrandt by intercourse with the Ulenburgs. Certainly Sandrart, who visited Holland in 1637, found Flinck acknowledged as one of Rembrandt's best pupils, and living habitually in the house of the dealer Hendrik Ulenburg at Amsterdam. For many years Flinck labored on the lines of Rembrandt, following that master's style in all the works which he executed between 1636 and 1648; then he fell into peculiar mannerisms by imitating the swelling forms and grand action of Rubens's creations. Finally he sailed with unfortunate complacency into the Dead Sea of official and diplomatic painting. Flinck's relations with Cleves became in time very important. He was introduced to the court of the Great Elector, Frederick William of Brandenburg, who married, in 1646, Louisa of Orange. He obtained the patronage of Johann Moritz of Orange, who was made stadtholder of Cleves in 1649. In 1652, a citizen of Amsterdam, Flinck married in 1656 an heiress, daughter of Ver Hoeven, a director of the Dutch East India Company. He was already well known even then in the patrician circles over which the burgomasters De Graef and the Echevin Six presided; he was on terms of intimacy with the poet Vondel and the treasurer Uitenbogaard. In his house, adorned with antique casts, costumes, and a noble collection of prints, he often received the stadtholder Johann Moritz, whose portrait is still preserved in the work of the learned Barleius.

The earliest of Flinck's authentic pieces is a likeness of a lady, dated 1636, in the gallery of Brunswick. His first subject picture is the Blessing of Jacob, in the Amsterdam museum (1638). Both are thoroughly Rembrandtesque in effect as well as in vigor of touch and warmth of flesh tints. The four "civic guards" of 1642, and "the twelve musketeers" with their president in an arm-chair (1648), in the town-hall at Amsterdam, are fine specimens of composed portrait groups. But the best of Flinck's productions in this style is the Peace of Münster in the museum of Amsterdam, a canvas with 19 life-sized figures full of animation in the faces, "radiant with Rembrandtesque color," and admirably distributed. Flinck here painted his own likeness to the left in a doorway. The mannered period of Flinck is amply illustrated in the Marcus Curius eating Turnips before the Samnite Envoys, and Solomon receiving Wisdom, in the palace on the Dam at Amsterdam. Here it is that Flinck shows most defects, being faulty in arrangement, gaudy in tint, flat and shallow in execution, and partial to whitened flesh that looks as if it had been smeared with violet powder and rouge. The chronology of Flinck's works, so far as they are seen in public galleries, comprises, in addition to the foregoing, the Grey Beard of 1639 at Dresden, the Girl of 1641 at the Louvre, a portrait group of a male and female (1646) at Rotterdam, a lady (1651) at Berlin. In November, 1659, the burgomaster of Amsterdam contracted with Flinck for 12 canvases to represent four heroic figures of David and Samson and Marcus Curius and Horatius Cocles, and scenes from the wars of the Batavians and Romans. Flinck was unable to finish more than the sketches. In the same year he received a flattering acknowledgment from the town council of Cleves on the completion of a picture of Solomon which was a counterpart of the composition at Amsterdam. This and other pictures and portraits, such as the likenesses of Frederick William of Brandenburg and Johann Moritz of Nassau, and the allegory of Louisa of Orange attended by Victory and Fame and other figures at the cradle of the first-born son of the elector, have disappeared. Of several pictures which were painted for the Great Kurfürst, none are preserved except the Expulsion of Hagar in the Berlin museum. Flinck's death at Amsterdam on the 22d of February, 1660, was sudden and unexpected.

FLINDERS, MATTHEW (1774–1814), English navigator, explorer, and man of science, was born at Donington, near Boston, in Lincolnshire, March 16, 1774. Matthew was at first designed to follow his father's profession of surgeon, but his enthusiasm in favor of a life of adventure impelled him to enter the royal navy, which he did, October 23, 1789. After a voyage to the Friendly Islands and West Indies, and after serving in the "Bellerophon" during Lord Howe's "glorious first of June" (1794) off Ushant, Flinders went out in 1795 as midshipman in the "Reliance" to New South Wales. For the next few years he devoted himself to the task of accurately laying down the outline and bearings of the Australian coast, and he did his work so thoroughly that he left comparatively little for his successors to do. With his friend George Bass, the surgeon of the "Reliance," in the year of his arrival he explored George's River; and, after a voyage to Norfolk Island, again in March, 1796, the two friends in the same boat, the "Tom Thumb," only 8 feet long, and with only a boy to help them, explored a stretch of coast to the south of Port Jackson. After a voyage to the Cape of Good Hope, when he was promoted to a lieutenancy, Flinders was engaged during February, 1798, in a survey of the Furneaux Islands, lying to the north of Tasmania. His delight was great when, in September of the same year, he was commissioned along with Bass, who had already explored the sea between Tasmania and the south coast to some extent and inferred that it was a strait, to proceed in the sloop "Norfolk" (25 tons) to prove conclusively that Van Diemen's Land was an island by circumnavigating it. In the same sloop, in the summer of next year, Flinders made an exploration to the north of Port Jackson, the object being mainly to survey Glasshouse Bay (Moreton Bay) and Hervey's Bay. Returning to England he was appointed to the command of an expedition for the thorough exploration of the coasts of Terra Australis, as the southern continent was still called, though Flinders is said to have been the first to suggest for it the name Australia. On July 18, 1801, the sloop "Investigator" (334 tons), in which the expedition sailed, left Spithead, Flinders being furnished with instructions and with a passport from the French Government to all their officials in the Eastern seas. Among the scientific staff was Robert Brown, one of the most eminent English botanists; and among the midshipmen was Flinders's relative, John Franklin, of Arctic fame. Cape Leeuwin, on the south-west coast of Australia, was reached on November 6, and King George's Sound on December 9. Flinders sailed round the Great Bight, examining the islands and indentations on the east side, noting the nature of the country, the people, products, etc., and paying special attention to the subject of the variation of the compass. Spencer and St. Vincent Gulfs were discovered and explored. On April 8, 1802, shortly after leaving Kangaroo Islands, at the mouth of St. Vincent Gulf, Flinders fell in with the French exploring ship, "Le Géographe," under Captain Nicolas Baudin, in the bay now known as Encounter Bay. In the narrative of the French expedition published in 1807 (when Flinders was a prisoner in the Mauritius) by M. Peron, the naturalist to the expedition, much of the land west of the point of meeting was claimed as having been discovered by Baudin, and French names were extensively substituted for the English ones given by Flinders. It was only in 1814, when Flinders published his own narrative, that the real state of the case was fully exposed. Flinders continued his examination of the coast along Bass's Strait, carefully surveying Port Phillip. Port Jackson was reached on May 9, 1802.

After staying at Port Jackson for about a couple of months, Flinders set out again on July 22 to complete his circumnavigation of Australia. The Great Barrier Reef was examined with the greatest care in several places. The north-east entrance of the Gulf of Carpentaria was reached early in November; and the next three months were spent in an examination of the shores of the gulf, and of the islands that skirt them. An inspection of the "Investigator" showed that she was in so leaky a condition that only with the greatest precaution could the voyage be completed in her. Flinders completed the survey of the Gulf of Carpentaria, and after touching at the island of Timor, the "Investigator" sailed round the west and south of Australia, and Port Jackson was reached on June 9, 1803. Much suffering was endured by nearly all the members of the expedition: a considerable proportion of the men succumbed to disease, and their leader was so reduced by scurvy that his health was greatly impaired.

Flinders determined to proceed home in H. M. S. "Porpoise" as a passenger, submit the results of his work to the Admiralty, and obtain, if possible, another vessel to complete his exploration of the Australian coast. The "Porpoise" left Port Jackson on August 10, accompanied by the H. E. I. C.'s ship "Bridgewater" (750 tons) and the "Cato" (450 tons) of London. On the night of the 17th, the "Porpoise" and "Cato" suddenly struck on a coral reef, and were rapidly reduced to wrecks. The officers and men encamped on a small sandbank near, 3 or 4 feet above high water, a considerable quantity of provisions, with many of the papers and charts, having been saved from the wrecks. The reef was in about 22° 11′ S. and 155° E., and about 800 miles from Port Jackson. Flinders returned to Port Jackson in a six-oared cutter in order to obtain a vessel to rescue the party. The reef was again reached on October 8, and all the officers and men having been satisfactorily disposed of, Flinders on the 11th left for Jones Strait in an unsound schooner of 29 tons, the "Cumberland," with ten companions, and a valuable collection of papers, charts, geological specimens, etc. On December 15 he put in at Mauritius, when he discovered that France and England were at war. The passport he possessed from the French Government was for the "Investigator;" still, though he was now on board another ship, his mission was essentially the same, and the work he was on was simply a continuation of that commenced in the unfortunate vessel. Nevertheless, on her arrival at Port Louis the "Cumberland" was seized by order of the governor-general De Caen. Flinders's papers were taken possession of, and he found himself virtually a prisoner. We need not dwell on the sad details of this unjustifiable captivity, which lasted to June, 1810. But there can be no doubt that the hardships and inactivity Flinders was compelled to endure for upwards of six years told seriously on his health, and brought his life to a premature end. He reached England in October, 1810, after an absence of upwards of nine years. The official red-tapeism of the day barred all promotion to the unfortunate explorer, who set himself to prepare an account of his explorations, though unfortunately an important part of his record had been retained by De Caen. The results of his labors were published in two large quarto volumes, entitled *A Voyage to Terra Australis*, with a folio volume of maps. The very day (July 19, 1814) on which his work was published Flinders died, at the early age of forty. The great work is a model of its kind, containing as it does not only a narrative of his own and of previous voyages, but masterly statements of the scientific results, especially with regard to magnetism, meteorology, hydrography, and navigation. Flinders paid great attention to the errors of the compass, especially to those caused by the presence of iron in ships. He is understood to have been the first to discover the source of such errors (which had scarcely been noticed before), and after investigating the laws of the variations, he suggested counter-attractions, an invention for which Professor Barlow got much credit many years afterwards. Numerous experiments on ships' magnetism were conducted at Portsmouth by Flinders, by order of the Admiralty, in 1812. Besides the *Voyage*, Flinders wrote *Observations on the Coast of Van Diemen's Land, Bass's Strait*, etc., and two papers in the *Phil. Trans.*,—one on the "Magnetic Needle" (1805), and the other "Observations on the Marine Barometer" (1806). (J. S. K.)

FLINT is a calcedonic variety of silica found in the form of irregular concretionary nodules of varying size, chiefly in the Upper Chalk beds and in other similar limestone deposits. The mode in which flint originated is not altogether satisfactorily explained; but as traces of some of the humbler marine organisms are almost invariably found in the nodules, it is assumed that the siliceous matter was partly derived from these organisms themselves, and that they formed nuclei around which soluble silica accumulated. From the prevalence of siliceous spiculæ of sponges in the nodules, it is affirmed by Dr. Bowerbank that all flints had, for their primary nuclei, the siliceous framework of the sponges which flourished in the depths of the sea during the Cretaceous epoch. Flints occur in the chalk in stratified order, and the various beds are possessed of a uniformly distinctive character. In some cases they are found in continuous layers, at other places they occur as isolated nodules. In the county of Norfolk, huge flints termed "potstones," of a pear-shaped outline, measuring as much as three feet in length by one foot across, are obtained; and these are embedded in the chalk at right angles to the horizontal layers of small flints. Flint is a compact homogeneous substance, externally coated with a white siliceous coat, and frequently hollow in the centre. It has a dark steely gray, almost black, sometimes brownish color; it is faintly translucent, and it breaks with a conchoidal or glassy fracture. In composition it consists of almost pure silica, partly in the crystalline or non-soluble quartzy form, and partly in the non-crystalline soluble state. It contains traces of lime, iron, and alumina, and when the proportion of lime present is large it passes into chert. When newly obtained from the pits the contained moisture of flint renders it easily flaked and otherwise worked, but after exposure to the air it becomes dry, hard, and intractable. From the earliest times flint has been employed as a fire-producer, by percussion with iron pyrites, and subsequently with a steel implement in the yet familiar form of "flint and steel." In classical authors occasional allusions are made to the use of flint knives; and the employment of flint and steel to produce fire is very pointedly described by Virgil and other writers. Except to a trifling extent in the preparation of strike-a-light flints, the only form in which flint industry now continues is in the fabrication of gun-flints, an occupation carried on at Brandon, and to a smaller extent at Icklingham, two villages in Suffolk. In 1876 there were 21 flint knappers in Brandon, and about 80,000 flints were sent away weekly, the greater proportion of which go to West Africa. The mining for flints is conducted by sinking a narrow pit into the chalk till the bed of suitable flints (the best are "floor-stones") is reached, and along this the miner drives a series of small galleries or burrows, carrying all the excavated material by hand to the surface. The knapper's tools consist of three simple forms of hammer and a chisel; and probably the only essential modification these tools have ever undergone consists in the substitution of metal for stone. The flint is first broken into convenient sized angular pieces, cubes of about 6 inches, called "quarters." The next operation, "flaking," consists in striking off, by means of carefully measured and well directed blows, flakes extending from end to end of the quarter, this process of flaking being continued till the quarter or core becomes too small to yield good flakes. The subsequent operation termed "knapping" consists in cutting or breaking the flakes transversely into the sizes required for gun-flints, each flake yielding two or three flints of different sizes. An expert flaker will make 7000 to 10,000 flakes in a day of twelve hours, and in the same time an average knapper will finish from flakes about 3000 gun-flints. Flint is also employed in building and for road metal. Calcined and powdered it is very much used in the manufacture of superior kinds of pottery. For the flint implements of primitive times, see ANTHROPOLOGY, vol. ii. p. 102, and ARCHÆOLOGY, vol. ii. p. 295.

FLINT, a maritime county of North Wales, the smallest but one of the Welsh and English counties, has an area of 264 square miles, or 169,162 acres; and (excluding the detached hundred of Maelor, which is divided from Denbighshire by the Dee, and bounded N. by Cheshire and S. and E. by Salop, lying 8 miles to the S.E. of the rest of the county) its boundaries are the estuary on the N., Cheshire on the N. and N.E., and Denbighshire with the Clwydian range to the S. and S.W. The greatest length of the county from S.E. to N.W. is 26 miles, and its breadth is from 10 to 12—Maelor being 9 miles by 5. The chief part of it is situate on the Coal-Measures and other members of the Carboniferous rocks group. A hilly tract of 50 miles breadth separates the Anglesey Coal-Measures from the Flintshire coal-field, which is again separated from that of Denbighshire to S.E. by the elevation of Mountain Limestone and Millstone Grit between Gresford and Hope. The latter runs continuously along the southern edge of the coal strata, followed, except in the extreme south, where we have the Wenlock rocks, by the Mountain Limestone. The extreme west and east, as well as the detached hundred, of the county is on the New Red Sandstone. Symonds says,—"The coal measures may be traced along the shore from Flint to the Point of Air; and the route from Flint to the west of Holywell crosses the Millstone Grit to the Mountain Limestone." The Wenlock rocks, of considerable altitude, forming the northern limb of the Berwen mountains, extend to within a mile of the shore of the Dee, near the western limit of the county, the margin still west being composed of the alluvial flat of Rhuddlan marsh and part of the vale of Clwyd. To the south the water-shed of the Berwens divides Flintshire and Denbighshire for some distance,—Moel Fammau, a member of the range common to both, rising to 1845 feet. This is high for Flintshire, though Buckley and Halkin mountains, with the rest of the hill system north and south, indicate a generally mountainous character. A narrow alluvial tract to the east lies parallel to that already mentioned in the extreme west, and both are connected by a fertile strip of reclaimed land on the south shore of the estuary. The hundred of Maelor is flat, fertile, and highly picturesque.

Flint has some lovely valleys, such as those of the Clwyd, partly in the county, and the Alyn, and dingles and ravines, such as the course of the Wepre brook from Ewloe Castle to the Dee. The chief rivers are the Dee, Clwyd, and Alyn. The Dee, entering the county near Overton, divides Maelor from Denbighshire on the west, and, after passing Chester, bounds it also on the north. The Clwyd, rising in Denbighshire, enters Flintshire near Bodfary, and after a brief northward course, joins the Elwy near Rhuddlan, past which they flow in one channel into the Irish Sea near Rhyl. The Alyn, a Denbighshire tributary, enters Flintshire near the base of Moel Fammau, winds between Cilcen and Mold,—with an underground course of half a mile, like fabled Alpheus, near Hesp-Alyn,—and then bending south to Caergwyrle, re-enters Denbighshire to join the Dee. Of Flintshire lakes, unimportant compared with those of neighboring counties, Llyn Helig near Whitford is the chief.

Sloping seaward, with a mild climate, a moderate elevation and shelter, and sufficient irrigation, Flintshire is well adapted for agriculture. Three-fourths of its area is under cultivation, as follows:—

Under corn crops..............	31,740	acres, of which wheat and oats occupy each one-third, and barley one-fourth.
Under green crops...........	8,315	acres, of which potatoes occupy one-fourth.
Under grass under rotation	16,809	acres.
Under permanent pasture...	66,509	acres.
Bare, fallow, etc...............	2,901	acres.
Total in cultivation.....	126,274	acres.

Of green crops, turnips and swedes are the chief; mangolds are little grown. To every 100 acres of cultivated land the proportion of horses is 4·5, of cattle 42·4, of sheep 100·8, and of pigs 11·8,—the cattle and pigs being about the same proportion as for Denbighshire, while the horses and sheep number only about one-half. Stock and dairy farming are keenly pursued by the Flintshire farmer, who crosses his native cattle with Herefords and Downs, his native sheep with Leicesters and Southdowns. Flintshire farms are of more than average size, and their occupiers are intelligent and progressive. In the thickly planted mining population they find a ready market for beef and mutton, as well as for cheese and butter.

With this important increment to their agricultural population, the census of 1871 gives Flintshire a population of 76,312, or an increase in ten years of above 6500. In 1801 the number was 39,469, so that the increase during the century has been nearly double. Flint is now one of the most densely peopled counties for its size, ranking the third in numbers of North Wales. Its collieries, of which there are 27 of note in the county, producing an annual average of 500,000 tons, begin at Llanasa, and run south-east through Whitford, Holywell, Flint, Halkin, Northop, Buckley, Mold, and Hawarden. Much of the yield is exported. Lead is raised in Halkin mountain, and in some nine or ten mines of note about Mold, Holywell, Prestatyn, and Talacre, near Llanasa, the average annual produce being about 1200 tons. The town of Holywell has been reckoned the headquarters of the "lead ore ticketings." In some cases it is smelted on the spot. Elsewhere it is sent to Bagilt, Flint, or Chester for that purpose. At Dyserth zinc is worked to a limited extent, and copper in Talargoch mine. Flintshire has also calamine mines; and in addition to frequent smelting works, large manufactories of oil, vitriol, potash, etc., employ the dwellers near the coast, while coarse clay-potteries, the products of which go by train and rail to Connagh's Quay, occupy those around Buckley. Little ironstone is now raised, the seams being thin and the yield low; but an important source of industry is the large limestone quarries, eight in number, which produce a quantity of building stone, burnt lime, and small stone for chemical works about Halkin and elsewhere.

In 1873 the county was divided between 3510 owners, of whom 2048, or 58 per cent. possessed less than one acre, or much the same proportion as Denbighshire (see vol. vii. p. 68). The average size of properties was 40½ acres, the average value per acre £2 13s. 8½d. More than one-third of the county is owned by 13 proprietors, viz., Lord Hanmer (Hanmer Hall), 7318 acres; Captain Conwy (Rhyl), 5526; Mostyn Trustees, 5460; Right Hon. W. E. Gladstone, 6908; Sir Piers Mostyn (Talacre), 4186; Sir Hugh Williams (Bodelwyddan), 4011; Lord Kenyon (Gredington), 4004; River Dee Company, 3679; Duke of Westminster (Halkin Castle), 3338; P. B. D. Cooke (Gwysaney), 3204; Earl of Denbigh (Downing), 2938; Edmund Peel (Overton), 2897; W. R. Hughes (St. Asaph), 2119. The county petty sessional divisions are—Mold; Northop; Hawarden and Broughton; Caergwyrle; Holywell; Caerwys; Rhyl, Prestatyn, and St. Asaph; and Hanmer. Flint borough has its separate commission of the peace, the borough magistrates holding their petty sessions at the town-hall for the borough district. The whole county constitutes one lieutenancy, and there are no highway districts. The principal towns are Flint, Mold, St. Asaph, Rhyl, Holywell.

Flint (said to be derived from a corruption of the documentary term "Castellum apud Fluentum" into "Apud le Flynt") is the capital and sole corporate town of the county, a seaport and contributory borough, 173 miles from London, on the south of the Dee estuary, between the sea and the hills inland. It has some good houses, and has recovered its decadence of twenty years ago since the establishment of vast chemical works, which make it the seat of great alkali manufactures, by Messrs. Muspratt Brothers, Huntley, and others. Its chief imports are sulphur and other chemicals; its exports coal, soda, potash, copper, and various chemical products. The church is not remarkable; but there are good parochial schools and several nonconformist chapels. The footways of the town are flagged, and there are other street improvements. Until five years ago the county jail occupied (as at Haverfordwest) an angle of the Edwardian Castle on the edge of the estuary; it was then removed to Mold—where, however, the new and costly jail has been closed by the New Prisons Act, and Flintshire prisoners are now sent to Chester Castle. The old Flint jail has been bought by the Messrs. Muspratt, and turned to good use as a "working men's club." It was in Flint Castle that Percy betrayed Richard II. to Bolingbroke in 1399. In 1643 it surrendered to the Roundheads, and four years later was dismantled. Its constable is still appointed by the crown, with duties limited since the Municipal Corporations Reforms Act to the care of the ruins,—a square court with towers at the angles abutting the sea, and a massive round tower with a drawbridge. Flint was made a borough by Edward I., and chartered by Edward III. and Edward the Black Prince, as earl of Chester. Since the Reform Act it is governed by a mayor, 4 aldermen, and 12 councillors. It is the nomination place for the group of contributory boroughs, viz., Flint, Caergwyrle, Caerwys, Overton, Rhuddlan, which with St. Asaph, Holywell, and Rhyl returns one member of parliament. In 1871 the population of Flint was 4269, as against 3296 in 1851.

Mold is a well-built town on the Alyn, in the south-east of Flintshire, the centre of a great coal and lead district, a terminus of the Chester and Holyhead branch railway, the assize town of the county, and the great locale of county business. Its restored church of the early 16th century is one of the finest in the diocese; and the Bailey Hill is the site of an ancient fortress stormed in 1144 and in 1322. The population of Mold is 12,237 by the last census.

St. Asaph, one of the four Welsh sees, and a cathedral town, lies near the confluence of the Elway and Clwyd. Founded originally by Kentigern, bishop of Glasgow, and named after his successor Asa, or Asaph, it still possesses, outlasting the buffets and vicissitudes of ages, its plain yet massive cruciform church. The population in 1871 of that part of the town which is situated in the county of Flint was 2806.

At the same census the winter population of the flourishing watering-place of *Rhyl* is given as 4229; but its summer average is from 10,000 to 12,000,—railway and water facilities bidding fair to eclipse the ancient neighboring borough of *Rhuddlan*, which was once of such importance that Edward I. held his parliament in it, and the Statutes of Rhuddlan were passed there. Population of Rhuddlan, 5525.

Holywell depends for its prosperity on its lead mines and lime-works, its copper, brass, and zinc, and its lead smelting. At the last census its population was 9980. It has a railway station on the Chester and Holyhead line, two miles from the town, and within a hundred yards of the Cistercian abbey of Basingwerk. Closer still is St. Winifred's well, the exquisite late Perpendicular chapel above which has been restored. Other places of antiquarian interest are Caerwys, on the Mold and Denbigh railway—with its streets at right angles and other indications of Roman occupation; Hope, or Hope Estyn, near Caergwyrle; and Overton, in the detached part of Flint. Bodfary retains the tradition of Roman occupation. There is a fortified British post at Moel-y-Gaer, near Northop, and a roadway at Halkin, near Whitford.

The history and antiquities of Flintshire are of some importance. Maes-y-Garmon, a mile from Mold, is the scene of the bloodless victory of the Britons under Germanus and Lupus over the Picts and Scots in 430 A.D., remembered as the "Alleluia victory." Bangor Iscoed, "the great high choir in Maelor," preserves the site of the monastery suddenly and totally destroyed with more than 2000 monks by Ethelfred of Northumberland in 607. Watt's Dyke and Offa's Dyke—supposed to have run, the former from the coast near Basingwerk, past Halkin, Hope, and the Alyn gorge, towards Oswestry, and the latter from Prestatyn southward towards Mold, Minera, and across the Severn over the Long Mountain—perpetuate the names, one of a local hero, the other of a great Mercian ruler. At Cynsyllt, or Coleshill, is the scene of a second defeat of Henry II. by Owain Gwynedd about a mile from Flint, the first having been at Coed Ewloe, where a lone tower remains to recall the tale. Tumuli, maenhirs, and inscribed stones are frequent in Flintshire, the most remarkable of the last being the "Maen Achwynfan" of the 9th to 12th century near Pantasa, and the 14th-century cross in Newmarket church-yard. Most of the Flint castles are Edwardian, that at Caergwyrle bespeaking an earlier Roman and even British occupation.

Flintshire is well provided with public elementary schools, viz., 68 voluntary and 4 board schools, and Church of England Sunday-schools. It belongs to the diocese of St. Asaph.

On the history of the county may be consulted *Archæologia Cumbrensis*, 3d series, vol. iii.; Thomas, *History of the Diocese of St. Asaph*, 1874; Pennant's *Tour in Wales*; Nicholas, *Annals of Welsh Counties and County Families*; *Notes on the History of the County Town of Flint*, by Henry Taylor, town-clerk of Flint, 1875; Murray's *Handbook of N. Wales*, 1874.

(J. DA.)

FLINT, Timothy (1780–1840), an American clergyman and writer, was born in Reading, Massachusetts, July 11, 1780. He graduated at Harvard College in the close of 1800. Settled as a Congregational minister in Lunenburg, Massachusetts, he pursued scientific studies with interest; and his labors in his laboratory seemed so strange to the people of that retired region, that some persons supposed and asserted that he was engaged in counterfeiting. This led to disagreeable complications, which resulted in his leaving his parish and becoming a missionary in the valley of the Mississippi. There could have been no discipline better adapted to correct his natural sensitiveness than his work at the West in those days, where he came into contact with many rough people and peculiar social habits. His observations on the manners and character of the settlers of the Ohio and Mississippi valleys were recorded in a very picturesque work called *Recollections of Ten Years passed in the Valley of the Mississippi*, Boston, 1826. This book passed to a second edition, and excited so much interest as to be translated into French as well as reprinted in England. Indeed, it was the first account of the Western States of America which brought to light the real life and character of the people. Flint had acquired this knowledge of the young communities of the West, not only by his journeys among them as an itinerant preacher, but also by having been for a short period teacher and farmer on the banks of the Mississippi and Red Rivers. The success which this work met with, together with the failing health of the writer, led him to relinquish his more active labors for literary pursuits. His subsequent publications were as follows:—*Francis Berrian, or the Mexican Patriot*, 1826,—a novel, the scene of which is laid in Mexico at the period of the revolution in which Iturbide was overthrown; *A Condensed Geography and History of the Western States in the Mississippi Valley*, 2 vols. 8vo, Cincin., 1828; *Arthur Clenning*, a novel, 1828; *George Mason, the Young Backwoodsman*, a novel; *Indian Wars in the West*, 1833; *Memoir of Daniel Boone*, 1834. In addition to these works, Flint published several translations from the French, and essays in the London *Athenæum*, the *Western Review*, and the *New York Knickerbocker*, of which last two magazines he was at different times editor. His style was vivid, plain, and forcible, and his matter interesting; the spirit of his writings was always humane and genial; the *Quarterly Review*, in a notice of his first book, says: "These pages reflect a sincere, humane, and liberal character, a warm and gentle heart, and hardly even a prejudice which is not amiable." He was very industrious, and had acquired such a power of abstraction that he prosecuted the labor of translating the *Biographie Universelle* in a room where other persons were engaged in work or conversation, being so absorbed in his work as to lose all consciousness of where he was or who was present. He died in Salem, August 16, 1840. His works on the Western States are still among the best we have on the subject.

FLODOARD, or Frodoart (894–966), a French chronicler, was born at Epernay in 894. He was educated at Rheims, and for some time held the office of canon in the cathedral of that city. The later years of his life were spent in retirement at a neighboring monastery, and were devoted to study and the exercises of piety. He died 28th March, 966. His works are the most important contribution to the French literature of his time, and consist of *Histoire de l'église de Rheims*; *Chronique sacrée*, a poetical history of Jesus Christ, the apostles, the popes, and the saints and martyrs of the church; and *Chronicon Rerum inter Francos gestarum*, which, beginning with the year 919 and ending with 966, throws more light than any other document on the annals of the 10th century. This work was first printed in the *Rerum Burgundicarum Chronicon*, Basel, 1575; and a translation of it was inserted by Guizot in his *Collection des Mémoires relatifs à l'Histoire de France*. The prose of Flodoard is very correct and elegant, but his poetry is no exception to the mechanical, unmusical, and common-place verses belonging to this period of literature.

FLOOD. See Deluge.

FLOOD, Henry (1732–1791), an eminent Irish orator and politician, born in 1732, was the son of the Right Honorable Warden Flood, chief-justice of the Queen's Bench in Ireland. He came of an old Kentish family, a branch of which had settled in Kilkenny during the Civil War. At the age of fifteen he was sent to Trinity College, Dublin; and he subsequently studied at Oxford under Markham, afterwards archbishop of York. On leaving the university with a good reputation for classical scholarship he proceeded to the Temple. Possessing a competent fortune, high social position, and considerable family influence, he determined to devote himself to a political life, and obtained a seat in the Irish House of Commons for his own county of Kilkenny. His abilities soon placed him in the position of a leader of the opposition or popular party, to which he rendered good service on several occasions. Among his more intimate friends at this time were the agreeable and gifted Lord Charlemont, Mr. Bushe, and the famous Grattan, who owed a good deal to Flood's assistance in entering upon public life. Though somewhat too solemn and dignified, Flood was an orator of considerable power, and especially master of that unsparing invective which was then one of the best employed weapons of debate, and which often degenerated into what would now be considered unwarrantable personalities. At that time, indeed, political rivalry frequently ended in personal hatred. In 1769 Flood had the misfortune to be involved in an election quarrel with a Mr. Agar. The result was a duel, and on the second exchange of shots Agar was mortally wounded. Flood was brought to trial, but acquitted. In 1775 Flood was persuaded to an act which seriously diminished his influence. He accepted the office of vice-treasurer under Lord Harcourt and the duke of Buckingham. But in 1780, in consequence of his strong sympathy with the cause of Irish independence and his position as lieutenant-colonel of the Irish volunteers, he felt obliged to resign this office, and in consequence he was removed by the Government from the council, treatment which he bitterly resented. His influence was now entirely devoted to the support of the popular party, which in fact he had never deserted. He was present at the great armed convention of the volunteers which met at Dungannon, and proposed a resolution that the powers exercised by the Privy Council were unconstitutional. After the passing of the Irish Bill of Right through the splendid efforts of Grattan, Flood made an attempt to achieve what he considered would be a still greater triumph. He declared that the mere repeal of the Act (6 Geo. I.) which had subjected Ireland to the control of the English parliament was not enough, and insisted upon an express renouncement of the right of the English parliament to interfere in any way with the government of Ireland. Grattan, maintaining that his own measure was sufficient, vigorously opposed the bill which Flood introduced; and the two orators, forgetting their old friendship, exchanged speeches full of the bitterest personal invective. The quarrel was about to end in a duel, and arrangements were actually being made for a meeting, when the affair was discovered, and both were bound over to keep the peace. Flood's bill was completely defeated, for it was altogether unnecessary, and could only have served as a triumph to Irish national vanity. In 1783 Flood obtained a seat in the English House of Commons (while retaining his seat in the Irish House), being elected M. P. for Winchester. He was afterwards (1785) member for Seaford. But his success was not such as he had enjoyed in Ireland, and his career in the English parliament was not of much importance. Perhaps his greatest effort was his speech against Pitt's famous commercial treaty. Flood died on the 2d December, 1791. He left £5000 a year to Trinity College, Dublin, part of which was to found a professorship of Irish and furnish prizes for English and Irish composition, but this destination of the bequest was set aside.

FLOOR CLOTH is a covering for the floors of lobbies, halls, passages, and other situations where there is much traffic and heavy wear. Originally floor-cloth consisted of a heavy canvas coated with painters' colors and ornamented with patterns executed with the brush. At a later period stencilled ornaments took the place of hand-painted patterns, and now ornamental designs are applied solely by means of hand-blocks. Kirkcaldy, in Scotland, is the leading centre of the oil floor-cloth manufacture, in which town it was firmly established by the energy of the late Michael Nairn—the operations of the firm founded by him being, it is understood, the most extensive in the trade. The brief outline of the manufacture which follows represents the processes as conducted in the extensive establishments of Shepherd and Beveridge of Kirkcaldy, where the mechanical and other arrangements have reached the highest perfection suggested by skill and experience.

The size of the canvas operated on, which must be free from all seams and joinings, is 8 yards wide by 25 yards long. The huge webs from which these canvases are cut are woven, chiefly in power-looms, in lengths of 150 yards, from which six floor-cloth pieces are obtained. For the cheaper qualities of floor-cloth jute canvas is employed, but in the best kinds the material is woven of stout tow yarn. The pieces of canvas in sizes above indicated are mounted on a series of stout wooden stretching frames, ranged about 30 inches apart from each other in a lofty, well-ventilated hall. The back or under part of the floor-cloth is first dealt with, the first operation being to coat the whole surface with thin size, which fills up the interstices and prevents the oil of the pigment from penetrating and rotting the fibres. The paint, which is next applied, is of the consistency of a thin plaster, and is made up of raw oil, some turpentine, and ochre, umber, and other earthy pigments. It is laid on, not with brushes, but with long trowels, the operation being called "trowelling," and the workmen go over a large surface with great expedition. When the operation is complete, the iron doors of the hall are closed and streams of heated, slightly moist air are blown by a fan blast into the apartment, a temperature of from 78° to 90° Fahr. being then maintained. The moisture in the heat is essential for keeping the paint while drying from shrinking, cracking, and scaling off. When the paint is dry the whole surface is smoothed with pumice, and the back is finished with a coat of thinner color, in which boiled oil without turpentine is employed, thereby securing a glossy surface and finish. As soon as the back is dry the face or upper side has to be turned to the workmen, an operation which demands great caution and precision to prevent the canvas from being torn and destroyed. The lower edge being carried up and secured along the top of the frame, the upper part is suddenly detached and let down to the floor. The face receives, in succession, a coat of size and three "trowelling" coats, with pumicing between, and on the conclusion of these operations it is ready for printing. The printing is a costly process, owing to the great store of blocks which it is found necessary to provide and keep up; and the colors used are also expensive, consisting, as they do, of the fine bright pigments with a foundation of white lead. The blocks have a printing surface of 18 square inches, cut either of pear tree or other wood, or with faces of type metal cast in wood matrices, the interstices being filled up with felt. The cost is further increased by the laborious and tedious nature of the operations, the printing of an eight-color pattern over a full piece requiring no less than 7200 separate applications of the set of eight color blocks and one finishing block. The cloth is brought to the printing-room by a kind of overhead tramway arrangement, where it is passed over a long narrow table. At the side of this stands the printer; and the color-table, on which is spread the color he is to print, is mounted on rails which run parallel to the table over which the cloth is spread. Guide bars are arranged over the cloth to secure that the various impressions fall on their proper places with the utmost precision, and overhead are suspended from a spring beam, screw presses which travel from end to end of the table. The block having received the needful amount of color, and being laid in position over the cloth, receives, by means of the movable screw press, a tight elastic squeeze, which secures a uniform impression of the portion of the pattern brought out by one color. The various colors are so printed in in succession, and thereafter the whole is gone over with a finishing block, the surface of which is cut into fine straight grooves or lines. Finally, the finished cloth is moved to a drying room, where, suspended by the two extremities face outwards, it is left to harden and season.

Oil floor-cloth is open to the objection that it has a hard, cold, and uncomfortable surface, while it is almost as noisy to the tread as ordinary wooden flooring. Many substances have been proposed to supplant it, in which these objectionable features have been more or less overcome, while they retain its advantages of resistance to wear, cleanness, and freedom from damp. Of these bodies linoleum has proved most successful in experience, but various other materials of a similar kind have been introduced and used to a considerable extent.

Kamptulicon is a variety of floor-cloth, which, although invented about 1843, did not receive prominent public notice till the London International Exhibition of 1862. The materials and processes employed in its manufacture vary considerably, but it is essentially a preparation of india-rubber masticated up with ground cork, the preparation and mixture being effected by repeated passing of the material between grooved rollers. When thoroughly incorporated the preparation is rolled out into sheets, sometimes over a backing of canvas, by passing it between pairs of wide and heavy steam-heated rollers. In addition to the substances above mentioned, gutta-percha, sawdust, peat-dust, ground leather, boiled oil, resins, pitch, asphalt, tar, chalk, and fibrous residues have all been used in kamptulicon making. The rolled sheets are ornamented by printing simple patterns on their surface, but, as much of the peculiar advantages of kamptulicon would be lost were its whole surface covered with oil pigments, the kamptulicon surface is, as far as possible, left exposed. Kamptulicon forms a warm, pleasant, soft, and noiseless floor-cloth, but the higher qualities, in which india-rubber and ground cork are the main ingredients, are rather expensive, and the manufacture has been curtailed since the introduction of linoleum.

Linoleum.—This substance consists of oxidized linseed oil combined with ground cork, treated and rolled very much in the same manner as kamptulicon, to which, in appearance and properties, it bears a close resemblance. The manufacture was first conducted under a series of patents secured by Mr. F. Walton, the essential feature of his process—his method of oxidizing linseed oil—having been patented in January, 1860. The oxidation was effected by mixing the oil, perfectly clear and bright, with a suitable drier, by preference from 5 to 10 per cent. of acetate of lead being used, and spreading it in thin films on surfaces of considerable extent, which films were exposed to currents of heated air. In this way a rapid oxidation was induced, the oil being transformed into linoxein, a slightly elastic semi-resinous body, having many properties in common with india-rubber, with the advantage of a clear semi-translucent yellow color. In his patent of December, 1863, dealing chiefly with the production of colored patterns on linoleum, Mr. Walton specifies, as a suitable composition for the body of the material, 4 cwt. of oxidized oil, $1\frac{1}{2}$ cwt. of resin, $\frac{1}{2}$ cwt. of kaurie-gum and coloring matter, mixed together in a steam-heated pan and cast into cakes. It was afterwards to be mixed with an equal weight of cork dust, or a somewhat larger quantity of sawdust, and spread on and pressed into a woven fabric between steam-heated rollers. The breadth of the finished linoleum is determined by the breadth of the spreading rollers through which it passes; at present that does not exceed six feet. The manufacture of linoleum is rapidly extending, and since the expiry of Mr. Walton's patent rights, it has been begun by the leading Kirkcaldy floor-clothmakers.

Boulinikon.—Under this name a kind of floor-cloth with a lineoleum-like surface is manufactured of waste materials, by a process patented in January, 1865, by John B. Wood. It is composed of about equal portions of raw buffalo or other hide macerated and reduced to a pulp, pulped cotton or linen rags, and coarse hair ground up short and fine. These are mixed into a common pulp in a form of rag engine, and subsequently spread, drained, dried, and pressed on a machine similar to that used in the paper manufacture. The ornamentation is effected in the manner employed for kamptulicon and linoleum; but the substance may be entirely covered with pigment and finished like oil floor-cloth. (J. PA.)

FLOR, ROGER DI, a military adventurer who, in the early years of the 14th century, distinguished himself as leader of the Catalan Grand Company. He was the second son of a falconer in the service of the emperor Frederick II., and when eight years old was sent to sea in a galley belonging to the Knights Templars. He entered the order, and became commander of a galley. At the siege of Acre by the Saracens in 1291 he absented himself, took no part in the defence of the town, and was accused of appropriating to his own use the treasures of his order. He was denounced to the pope by the grand master as a thief and an apostate, was degraded from his rank, and threatened with arrest. To escape imprisonment he fled to Genoa, where he began to play the pirate. The struggle between the kings of Aragon and the French kings of Naples for the possession of Sicily was at this time going on; and Roger entered the service of Frederick, king of Sicily, who gave him the rank of vice-admiral. At the close of the war, in 1302, Frederick being anxious to free the island from the auxiliaries whom he had no longer the means of paying, Roger induced his followers to seek new adventures in the East, in fighting against the Turks, who were ravaging the empire. The emperor Andronicus II. accepted his offer of service; and in September, 1303, Roger with his fleet and army arrived at Constantinople. He was adopted into the imperial family, was married to a granddaughter of the emperor, and was made grand duke and commander-in-chief of the army and the fleet. After some weeks lost in dissipation, intrigues, and bloody quarrels, Roger and his men were sent into Asia, and after some successful encounters with the Turks they went into winter quarters at Cyzicus. In May, 1304, they again took the field, and rendered the important service of relieving Philadelphia, then invested and reduced to extremities by the Turks. But Roger, bent on advancing his own interests rather than those of the emperor, determined to found in the East a principality for himself. He sent his treasures to Magnesia, but the people slew his Catalans and seized the treasures. He then formed the siege of the town, but his attacks were repulsed, and he was compelled to raise the siege. Passing over into Europe, he settled his troops in Gallipoli and other towns, and visited Constantinople to demand pay for the Grand Company. Dissatisfied with the small sum granted by the emperor, he plundered the country and carried on intrigues both with and against the emperor. In the spring of 1306 Roger was created Cæsar, this being the first time that the title was given to a mere adventurer. Before setting out on a second expedition to Philadelphia, he visited the young emperor Michael at Adrianople; and there he was assassinated and his Catalan cavalry were massacred, April 4, 1306. His death was avenged by a war which was fiercely waged by the Grand Company against the Greeks.

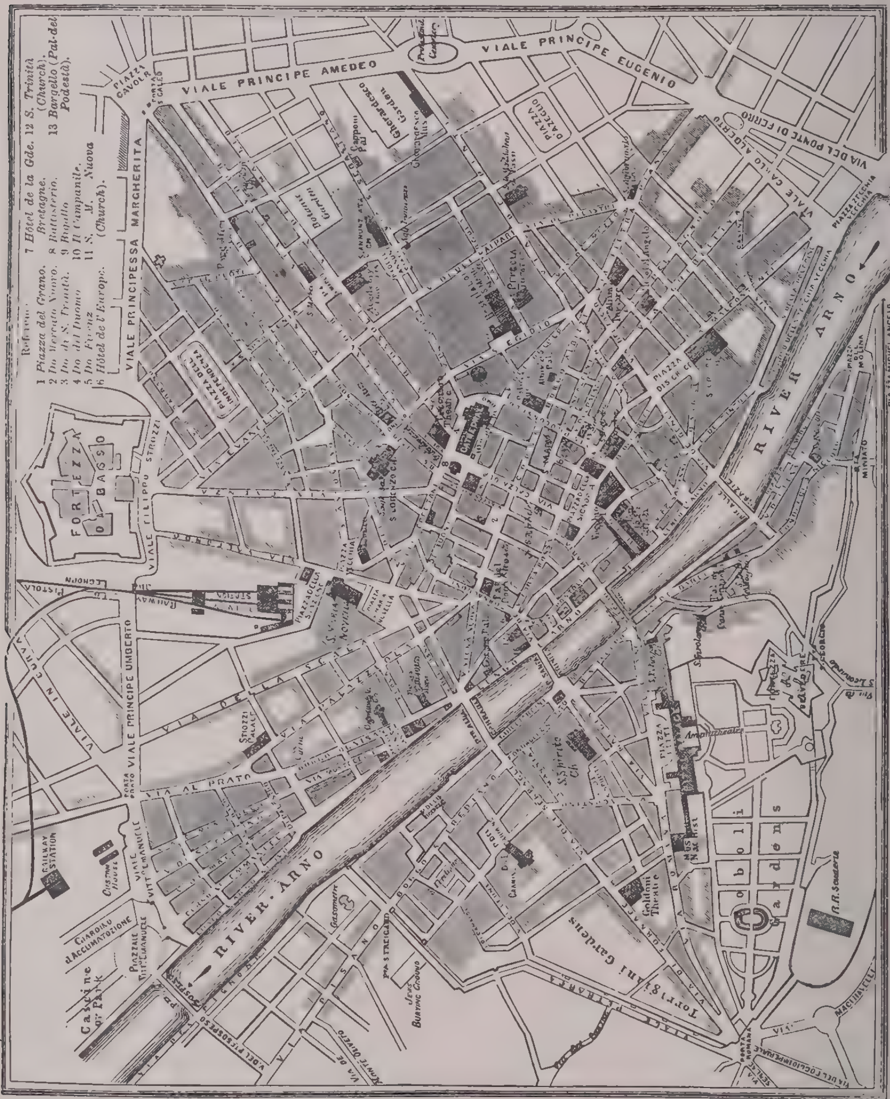
FLORA, in Roman mythology, a goddess of spring-time and flowers, to whom for her fostering influence a festival (*Floralia*) of great gayety and perhaps excessive license was held in Rome, at first irregularly, but after 173 B.C. annually, with increasing popularity. This festival was extended to five days, April 28 to May 3, the date of April 28 answering to the foundation day of the temple of Flora near the Circus Maximus. To her worship was attached a Flamen Floralis.

FLORENCE (Italian *Firenze*, ancient *Florentia*), the capital of Tuscany, now a province of the kingdom of Italy, is an archiepiscopal see. It is situated 125 miles north of Rome, 43° 50′ N. lat., 11° 14 E. long., on both sides of the river Arno, which here flows through a wide valley, bounded by spurs of the Apennine range to the north, and by lower hills to the south of the city. The bed of the river at Florence is 138 feet above the Mediterranean. The geological formation of the surrounding country is Upper Cretaceous and Older Tertiary, partly covered by the fossiliferous upper Arno beds of Newer Tertiary, containing elephant bones. Pietra forte, belonging to the Cretaceous, a durable sandstone with calcareous ingredients, is largely quarried south of Florence, and has been used for centuries as paving-stones for the city, as well as in the construction of the city walls, the palazzi, churches, etc. North of Florence, pietra serena or macigno, a pure sandstone belonging to the Tertiary beds, is likewise worked for building purposes; its texture being finer than that of the pietra forte, it has been adopted for the interior of churches and houses.

The soil is remarkably fertile: corn, vines, and olives cover hill and valley, while the mountains, which rise above 3000 feet, have the cypress, ilex, chestnut, and pine. The country is celebrated for the abundance of its flowers. and presents a rich field for the botanist.

Climate and Sanitary Condition.—The climate of Florence is extremely variable, especially in the early spring, when the inhabitants are liable to diseases of the trachea, to bronchitis, and affections of the lungs. The summers are hot; but both the summers and autumns are peculiarly healthy, when the city is entirely free from intermittent fever, while typhoid fever is of rare occurrence. Eruptive diseases and all children's complaints are exceedingly mild. Diphtheria appeared first in 1868, and continued as a severe epidemic until 1872, since which time it has only occurred at intervals and in isolated cases. Cholera has more than once visited Florence with severity, but the last time it was in Italy this city escaped the calamity. The migliaria, so much dreaded by the Florentines, is not confined to Italy, but here, as elsewhere, is found to be an accompaniment of typhoid fever, pneumonia, and some other diseases. The average temperature throughout the year is about 15° centigrade (59° Fahr.). The greatest summer heat averages 36° centigrade (96·8° Fahr.), but it has risen exceptionally to 39° centigrade (102·2° Fahr.). The greatest cold is about 6° centigrade below zero (21·2° Fahr.). The longest day is 15 hours 23 minutes; the shortest, 8 hours 50 minutes. The average annual rainfall is about 9 inches. The drainage of the city is imperfect, and it is ill supplied with water, which is largely impregnated with carbonate of lime. The wells are shallow, not above 20 or 22 feet deep. The best drinking water is conveyed in pipes from a distance of seven miles north of Florence to the Palazzo Pitti. The water of the Arno above the town has latterly been filtered and pumped up to a reservoir for distribution in the city.

Public Buildings, Parks, and Charitable Foundations.—Florence contains more than 170 churches, several of which are Italian Evangelical, besides English, American, French, and German Protestant, and a large Jewish synagogue lately erected. The most remarkable are the Badia or ancient abbey, the cathedral with its campanile, and the baptistery, Sta. Maria Novella, San Marco, the SS. Annunziata, and Or San Michele, with San Miniato and San Francesco beyond the walls. Of the palaces, whose construction of rough hewn stone gives a peculiar character to the city, those of greatest interest are the royal residence of the Pitti, the Palazzo Vecchio or municipal palace, and the Palazzo Riccardi, once the mansion of the Medici, but now the palace of the prefect. To these may be added the private palaces of the Strozzi, Rucellai, Corsini, Corsi, Quaratesi, Gondi, Albizzi, and Alessandri. The streets of modern Florence bear the names of many illustrious citizens of the past, and in the older narrower streets which have been left standing, the former homes of Dante, Macchiavelli, Guicciardini, etc., have tablets with their names inscribed. Some of the tabernacles, or frames containing pictures of sacred subjects, with lamps burning before them, still remain, commemorating the ancient usage of praying in the corners of the streets. The walls of Florence north of the Arno have been demolished, leaving the gates isolated, huge monuments of the past. South of the Arno the four gates of Romana, San Frediano, San Giorgio, and San Nicolo, remain as of old.



Plan of Florence.

The city is intersected from S.E. to N.W. by the river, which is crossed by six bridges. Two are suspension bridges, the remaining four of stone. The Ponte Vecchio, or jeweller's bridge, alone retains its ancient form, and is still flanked on both sides by goldsmiths' shops; the bridge of the S. Trinità is adorned with statues, and is remarkable for the perfect symmetry of the arches. The fortresses of Belvedere and Del Basso are now only used as barracks for soldiers. Since the annexation of Tuscany to the Italian kingdom the convents in Florence have been suppressed. A few monks are allowed to remain in each sanctuary, but the Government has prohibited any new monks or nuns to be added to the present number. This prohibition is, however, constantly evaded, and some of the schools for the young continue in their hands. There are twelve hospitals, including those for the blind, deaf and dumb, and insane.

The hospital for the sick of Sta. Maria Nuova was founded by Folco Portinari, the father of Dante's Beatrice, and the institute for the relief of the poveri vergognosi, or those ashamed to beg, by the good bishop Antonino, in the 15th century. One of the most important and beneficial charities is that of the Misericordia, or brothers of mercy. Florentines of all ranks belong to the society, and the members are equally bound to lend their services without remuneration when summoned, either to convey sick or wounded persons to the hospital, to nurse them in their homes, or to carry the dead to burial. Next in antiquity is the Bigallo for the reception of orphans or children abandoned by their parents, as well as the Innocenti or Foundling Hospital. The most admirably conducted modern charity is the workhouse or Pia Casa di Lavoro of Monte Domini. The building comprises two former convents; the Pia Casa is self-supporting, and independent of the municipality. None are admitted who are able-bodied, or who have relations capable of supporting them. An excellent education is provided for the boys, who are taught a trade by being bound apprentices to one of the workshops attached to the establishment. The girls are provided with dowries when they leave the Pia Casa.

There are nine theatres, and several public parks or gardens. The Cascine, a large extent of ground surrounding a fancy farm formerly belonging to the grand dukes, and planted in long avenues of ilex and other trees, is the fashionable resort of the Florentine nobility. The Strada dei Colli, outside the Porta Romana, winds round the hills of Arcetri and San Miniato, affording a magnificent prospect over Florence. The Boboli garden, behind the Pitti, and belonging to the royal palace, is open twice a week to the public, and, with its trim alleys, quaint terraces, statues, and fountains, is the delight of the Florentines.

Galleries of Art and Libraries.—Besides some excellent private collections, such as those of the Torrigiani, Corsini, and Strozzi, the Uffizi contains a very fine gallery of paintings, especially of the Tuscan school, but including several of Raphael's and Titian's masterpieces. The greatest treasures of the gallery are contained in one room called the Tribune, where are also placed the most celebrated statues of antiquity. A suite of small rooms contains some admirable specimens of other schools of painting. In one of the larger rooms is the famous group of the Niobe; two others are filled with portraits of artists, chiefly by their own hands; and there are, besides, valuable collections of busts, coins, medals, gems, engravings, and drawings by the old masters. The Pitti collection of paintings is perhaps the finest in the world, not only from the *chefs d'œuvre* of the great masters, but from the small number of pictures which may be considered of even mediocre merit. The Academy is assigned for the best examples of early art down to the time of Fra Angelico and Perugino; and connected with it are the cloisters of the former convent of the Scalzo or barefooted friars, where are some of the finest works of Andrea del Sarto in chiaroscuro. The Egyptian museum in the Via Faenza is small, but contains several objects of interest, and the museum of Etruscan art under the same roof is peculiarly important from a life-size bronze statue, a marble Greek sarcophagus with a colored representation of the battles between the Greeks and Amazons, and a terra-cotta statue of a lady in the costume of the third century before Christ. Here also is an interesting fresco of the Last Supper attributed to Raphael, whilst the Convent de' Pazzi possesses the finest work of his master Perugino, a Crucifixion, now open to the public.

There are three large and valuable libraries in the city: the National library, which unites the former library of the Pitti with the Magliabecchian, the two together containing 280,000 volumes; the Marucelliana, chiefly remarkable for important works on art; and the Laurentian, founded by Lorenzo de' Medici, and attached to the convent of San Lorenzo. This last is rich in a collection of more than 9000 valuable manuscripts, as well as illuminated Bibles and missals, and possesses about 20,000 volumes of print. The pride of the collection is an original and perhaps unique copy of the Pandects of Justinian.

University and Schools.—The university of Florence, which is rather an institute for advanced studies,—Istituti de' Studi Superiori Pratici e di Perfezionamento,—has its origin as far back as the year 1348. It was divided into six "scholæ," viz., theology, jurisprudence, medicines, belles lettres, Greek and Latin literature, and astrology or astronomy. To counteract the effects of the plague, which in the year just mentioned had decimated Florence and caused the city to be avoided by strangers, it was decreed that no one living within the walls, or even in the territory of the republic, should be allowed to seek an education abroad, and that those youths who were already attending other lyceums should forthwith return to their native city. In 1421 there were already 42 professors, and although in 1472 the Medici desired to revive the splendor of the Pisan university, and transferred several of the chairs from the city to Pisa, Florence retained many distinguished professors. The university underwent various changes, both in organization and name, but continued to flourish under the Medicean grand dukes. It gave rise to several academies, the most ancient of which was the Platonic, founded by Marsilio Ficino, for the cultivation of Greek literature, the Florentine academy, and the Accademia del Cimento (discussion) which had its rise with Galileo and his scholars. The Accademia della Crusca—named from *crusca* (bran) to express sifting the language—was founded in 1552, and the agricultural academy of the Georgofili in 1783. The taste for botany of Cosimo I. led to the formation of a herbal garden (Giardino de' Semplici)—and ultimately to the botanic garden under the walls of the Boboli. Natural science first formed a branch of study under the patronage of the Medici, who invited foreigners of scientific distinction to Florence. A vast collection of objects of natural science and physics having accumulated, the celebrated professor Giovanni Targioni Tozzetti, in the 18th century, threw them open to the public. The observatory, once attached to the museum, has been removed to a height corresponding with that on which Galileo made his observations. The collection in the museum was enriched by the valuable waxen anatomical preparations of Giulio Zummo of Syracuse, and by a unique collection of physical instruments most of which had belonged to the Accademia di Cimento. The university was reorganized in 1859, when Baron Ricasoli presided over Tuscany. Several new professorships were founded, in law, philosophy, and philology. In 1869 a chair of anthropology was added. The medical school of Sta. Maria Nuova has also been attached to the university. At one time the students of law, medicine, and natural science were expected to pursue their studies, first in Pisa, and the last two years in Florence, where they received their degrees. This has again been modified, and students in Florence have now the option of receiving degrees in Florence, Siena, or Pisa. Natural science degrees are conferred at the Specula, or institute of natural science, in the Via Romana.

The communal or municipal schools, where the pupils are admitted gratis, have increased enormously. From 4 schools under the last grand-duke, there are now, besides 32 elementary schools, 15 lyceums, of which three are for girls, and one of these a normal school for the training of teachers. The entire number of pupils in the schools averages 7900.

The *manufactures* are few and of small importance, that of silk standing first. The cultivation of the silk-worm and straw plaiting are the usual occupations of the people. The porcelain manufacture of the Marchese Ginori at Doccia, a few miles from Florence, has greatly fallen off in work as well as reputation; but a successful attempt to revive majolica ware has recently been made by Signor Cantigalli, whose manufactory is beyond the Porta Romana.

Administration.—Florence is governed by a prefect or representative of the chief government, who has a force of carabineers (mounted police) at his disposal, besides guardie di sicurezza, partly paid by the muncipality although there is also a city police. The ancient office of gonfalonier is replaced by that of syndic, who is president of the junta or municipal council. The city is divided into four electoral districts, and sends four deputies to parliament. Every male inhabitant above twenty-five years of age has the right of suffrage, although twenty-one is the usual age qualifying for official posts in Italy.

Population.—The population of Florence is very fluctuating. In 1854 the inhabitants numbered 115,675, but during the short period when it was the capital of the new kingdom there was a large increase of Italians as well as foreigners; this diminished as rapidly on the transference of the capital to Rome. By the census taken December 31, 1871, the total population, foreigners included, amounted to 167,093. On December 23, 1876, the number had risen to 176,121. In 1871 there were 158,704 Italian Roman Catholics, 917 Italian Protestants, 2366 Jews, and 5106 of other sects.

The Florentines are gentle and courteous in their manners, though retaining the republican feeling of equality, and are well disposed towards all who treat them with kindness and respect. They are justly proud of the traditions of their native city, but are hardly conscious that centuries of misgovernment have left them behind in the race of civilization. Though the advantages of a liberal education are now open to them, and they are remarkably rapid in acquisition, the more important moral training is still wanting,—a defect which, with the absence of chivalrous respect for women, renders men of all classes, as is too much the case also in other parts of Italy, tyrannical to their wives and children, as well as indifferent to the sufferings of the lower animals, all alike being regarded as property, over which they have an absolute control. From their nervous physical organization the Florentines are defective in manly courage, but peculiarly sensitive to the beautiful in art, and able to reproduce all that is delicate and refined in decoration. As, however, with the decline of the healthy vigor and simple lives of their ancestors they have lost much of their originality, modern sculpture and painting are in general feeble, and wanting in truth of expression and color. Though indolent and incapable of great exertion, the lower orders are industrious, and though impetuous, they have displayed exemplary patience and moderation in times of adversity. Their greatest misfortunes are the passion for gambling, with other vices remaining from a corrupt state of society, and the extremes of superstition and scepticism, which belong to the state of transition, political and religious, of the present era in Italy (1878). The large middle class, however, besides producing men eminent in literature and science, is rising in social and political importance, and by their intelligence and domestic virtues may well redeem faults in their fellow citizens, which are to be regarded rather as the result of adverse circumstances, than as a constant factor in the character of the Florentine people.

History.—Florence was originally a small trading village belonging to the Etruscan city of Fiesole, whence merchandise was sent down the Arno to Pisa, then a seaport. When colonized by the soldiers of Sulla, it gradually attained the dignity of a city, with the rank and privileges of a municipium. The name Florentia may have been derived from Florinus, a Roman general, or from Fluentia, because situated at the confluence of the Arno and Mugnone, or from the profusion of flowers growing in the vicinity. In the reign of Tiberius Cæsar the Florentines sent an embassy to Rome to deprecate a decree of the Roman senate, by which, in order to check the inundations caused by the number of tributary streams flowing into the Tiber, it had been proposed to turn the Chiano into the Arno. Christianity was first introduced in 313 A.D., and the most celebrated of early Florentine bishops was Zanobius, who died in 417, and to whom various miracles are ascribed. During his lifetime an invading army of barbarians approached Florence, but were defeated and destroyed in the fastnesses near Fiesole by the Roman general Stilicho. The Florentines, however, attributed the preservation of their city to the prayers of Zanobius. The victory was won in 405 on the 8th October, a day dedicated to a youthful saint, Reparata, who is said to have appeared in the midst of the battle, bearing in her hand a blood-red banner with the device of the white lily, which from that time became the badge of the city, whilst a new cathedral, built on the site of the old church of San Salvador, received her name. Florence had suffered the fate of other Italian cities at the hands of northern invaders, when Charlemagne, on his way to Rome, rebuilt its walls. Commerce began to flourish in the 10th century, when as yet German nobles or their descendants, who held their castles in fief of the German emperors, dwelt beyond the city. The pope, because an Italian sovereign, was regarded as the representative of national independence, and when Tuscany fell to the inheritance of the Countess Matilda, the Florentines found in her a patriotic champion of their rights, as well as a staunch adherent of the reigning pope, Gregory VII. A second circle of walls was built as a protection against the imperialists, and Matilda obliged some of the powerful nobles in the neighborhood to yield their lands to the canons of Sta. Reparata. She died in 1115, leaving a name so beloved by the Florentines that their female children were frequently christened Contessa, or Tessa, in remembrance of their benefactress. As the Florentines conquered and destroyed the castles of the robber chieftains who infested their neighborhood, they obliged them to reside within their city—an impolitic measure, which sowed the seeds of future discord and civic war. The romantic story of the Buondelmonti, whose assassination in 1215, for a breach of promise of marriage, occasioned a fierce outbreak of strife, is an instance of the many feuds that caused bloodshed in Florence during centuries.

About 1240 the Paterini, a sect of Reformers, after the manner of the Albigenses in France, had gained considerably in numbers and influence, especially among the imperialists, who about this time assumed the name of Ghibellines. Their adversaries, the Guelphic or papal party, called in Peter Martyr, a Dominican friar of Verona, to rouse the multitude for the destruction of this heresy. Two columns in Florence still mark the spots where the Paterini were massacred. A few years later the Guelphic Florentines sustained a severe defeat from Manfred, a natural son of the emperor Frederick II., at Monteaperti near Siena; and the Ghibellines, whom they had banished, re-entered Florence. The Ghibelline conquerors proposed to level the city with the ground, but were deterred by the bold and determined opposition of one of their own party, Farinata degli Uberti, whose name has been immortalized by Dante. About this time a French pope, Clement IV., invited Charles of Anjou, brother of Louis IX. of France, to take possession of Naples and drive the imperialists from Italy; and after the defeat and death of Manfred at Benevento, Charles complied with the request of the Florentine Guelphs, to assume the lordship of their city. In 1282, however, the wealthier guilds of Florence established a form of government or signory of their own, consisting of members chosen among themselves with the title of priors. Not satisfied with having driven their Ghibelline rivals into banishment, they sent an army to encounter them at Campaldino, where the Ghibellines were defeated with great slaughter. To arrest the power of the nobles within the city, a new code was framed in 1293, which went so far as to exclude them from their rights as citizens, and an officer was appointed—gonfaloniere di giustizia (standard-bearer of justice)—with a guard of soldiers to enforce the laws. Seventy-two families were declared incapable of holding office, and as they naturally combined in self-defence, peace seemed as far removed as ever from the walls of Florence.

The 13th century is one of the most important in the annals of the city. When Boniface VIII. held his jubilee in 1300, twelve of the ambassadors representing foreign powers were Florentines. So vast were the riches of Florence at this period, that when a citizen of Verona beheld the yet unfinished campanile, and exclaimed that the wealth of two monarchies would not suffice for such a monument, he was shown the public treasury to convince him that were the Florentines so inclined they could build their whole city of marble. The most illustrious of Florentine citizens, as well as poets, Dante Alighieri, born in 1265, was present at the battle of Campaldino in 1289, and was chosen prior of the republic in 1300. In his immortal poem, the *Divina Commedia*, he has preserved the names and deeds of the great men who made Florence renowned by their works. The friend of Dante, Guido Cavalcante, was considered no mean poet, and among the historians or chroniclers Dino Compagni and Giovanni Villani have left faithful records of their age. Cimabue commenced a new era in painting, and his pupil Giotto carried the art still further. Pre-eminent also in sculpture and architecture, in which Nicolo Pisano had led the way by his study of Greek art, Giotti built the beautiful campanile of the cathedral. St. Croce, founded in 1297, and the new cathedral of St. Maria del Fiore, were the work of the celebrated architect Arnolfo di Cambio. The exquisite church of Sta. Maria Novella was also begun in this century. The bridge of Rubaconte or Delle Grazie, and that of Carraia, were added to the Ponte Vecchio, and thus the two sides of the river were connected by three thoroughfares, although before the 13th century there had been no houses of importance south of the Arno.

With the commencement of the 14th century the parties which contended for power in Florence had assumed new names. On one side were the Bianchi, including the remnant of the old Ghibelline faction, but now representing the popular party; on the other, the Neri or Guelphs, who, under their leader, Corso Donati, represented the nobles or aristocracy of the city. Each party as it gained the ascendency sent its opponents into exile, until Pope Boniface VIII. again resorted to the fatal expedient of sending for a French prince, Charles of Valois, to restore order, and establish papal supremacy in the peninsula. When Charles arrived in Florence, he gave full license to the Neri to pillage the city, and avenge their wrongs. The signory endeavored to conciliate him by bribes, a measure to which Dante, then a prior, refused his consent, thus leading to his own banishment. A few years later the emperor Henry of Luxembourg descended into Italy, and the Florentines, whilst boldly preparing to resist his pretensions, added a third circuit of walls to their city. His death in 1313 put an end to this danger.

In a war with Castruccio Castracani, the tyrant of Lucca and Pisa, the Florentines sought the assistance of Robert, king of Naples, the son of Charles of Valois; but soon becoming jealous of the foreign power they had themselves invited, they created a new officer of justice, called the Bargello or head of police, who exercised his authority with so much cruelty that for a few months Florence was subjected to a reign of terror. During another war with Lucca, the Florentines again applied to Robert of Naples, who sent them his son, the duke of Calabria. He was accompanied by Walter de Brienne, duke of Athens, who, acting as lieutenant for the young prince, set aside the government of the priors, and ruled Florence with a rod of iron. The people could not long endure his acts of savage cruelty, and drove him from their city, after having put his minions to death in a manner so barbarous as to rival the deeds of the tyrant they had expelled. Tumults, a famine, and lastly the plague, devastated the land; and as a culmination of disasters, the mercenary troops employed everywhere in Italy roamed over the country and spread desolation wherever they came.

In 1378 occurred the famous rebellion of the Ciompi (Wooden Shoes), in which the artisans of Florence, led by a wool-carder, Michele di Lando, gained possession of the Palazzo Vecchio, and turned out the signory. Lando proved himself a man of sense and courage; he finally quelled the riot in which he had been engaged but had not roused, and restored the authority of the government. It was about this period that Salvestro de' Medici, Bettino Ricasoli, and Gino Capponi were among the leading men of the republic. From the riot of the Ciompi to the year 1390 Florence enjoyed the rare blessing of peace. This was broken by the ambitious thirst for universal dominion of Gian Galeazzo Visconti, lord of Milan, and Florence owed her preservation to her general, Sir John Hawkwood, an Essex tailor, who had joined the mercenary bands on the Continent, and earned himself wealth and celebrity as one of the greatest commanders of the age. The death of Gian Galeazzo in 1402 terminated the war. In 1406 the Florentines gained possession of their ancient rival Pisa after a long and cruel siege. The fall of Pisa put an end to the power of the Ghibelline or feudal party in Tuscany. In 1414, at the council of Constance, Pope John XXIII. was deposed, and came to reside in Florence, where his monument in the baptistery is one of the finest works of Donatello.

The wealth of the city was meantime always increasing, and manufactures of silk and woollen articles flourished within her walls. The richest of her citizens, Giovanni de' Medici, was chosen gonfalonier in 1426, but the popularity of this family had begun to excite the apprehension of all true patriots. When Giovanni introduced the "catasta," or inquiry into the possessions of every citizen, with a view to taxation according to their means—a measure favorably viewed by the lower orders,—it raised loud opposition on the part of the wealthy; for, however great their riches, none could compete with the Medici, and they saw in the "catasta" another stepping stone to raise their rival to greater power and authority. At Giovanni's death his popularity descended to his eldest son Cosimo, who lived to be called (however undeservedly) the father of his country. From him descended Lorenzo the Magnificent, Popes Leo X. and Clement VII., Catharine de' Medici queen of Henry II. of France, and Alexander, the first duke of Florence. From Giovanni's younger son Lorenzo descended the grand-dukes from Cosimo I. to Gian Gastone. Cosimo de' Medici and Rinaldo dei Albizzi represented the two great families who aspired to rule Florence. The Albizzi for a short time gained the ascendency, and Cosimo was sent into exile. Before a year he was recalled, and was created ganfalonier, and the Albizzi were banished.

In 1441 an œcumenical council was held in Florence by Pope Eugenius IV., to settle the claims of the Latin and Greek Churches, when learned men arrived from the East, and introduced the study of Greek classical authors. Neri Capponi alone ventured to oppose the ambition of the Medici, and it was said of him that, if Cosimo was the wealthiest man, Neri was the wisest in Florence; but the death of Capponi in 1457 left the Medici without a rival. The death of Cosimo's favorite son Giovanni in 1463 cast a gloom over the few remaining months of his own life, for his surviving son Pietro was a man enfeebled by disease. At the death of Pietro in 1469, his young son Lorenzo relates how the principal men of the city and of the state came to their house to condole with them on their loss, and to encourage him to take on himself the care of the city and government, as his grandfather and father had done. In 1470 Lorenzo was created syndic, and the next year he entertained with the utmost magnificence Galeazzo Sforza, duke of Milan. In 1472 Volterra was added to the Florentine dominions. Such horrible atrocities were committed during the siege and sack of this city, that the crime lay heavy on Lorenzo's conscience in his dying hour. In the Pazzi conspiracy of 1478 Lorenzo narrowly escaped with his life, whilst his brother Giovanni was murdered before the altar of the cathedral. The conspirators were put to death with great barbarity, and Lorenzo's popularity rose higher than ever. Surrounded by men of genius and learning whom his wealth could buy, or the charms of his manners and accomplishments could attract, Lorenzo added to the honors of his native city by reviving Greek taste and culture.

The appearance of Girolamo Savonarola, or the "Frate," as he was called in Florence, awoke a new spirit. His denunciation of the immoral lives of the citizens, and of books and works of art which tended to lower rather than exalt human nature, including the writings of Lorenzo himself, were listened to by crowded audiences. Such was his influence that even Lorenzo, when on his death-bed in 1492, sent for the "Frate" to receive his confession, and grant him absolution. That absolution Savonarola refused, unless Lorenzo repented of his usurpations, and promised to restore a free government to Florence; but to this Lorenzo would not consent, and he died unshriven. The dawn of art and literature in the 13th century had attained its greatest brilliancy in the 14th and 15th. Before the Medici had risen to power, the city had been embellished by the works of Andrea Orcagna, Taddeo Gaddi, Fra Filippo Lippi, Fra Angelico, Andrea Castagno, Donatello, and Desiderio di Settignano; Ghiberti had designed his Gates of Paradise for the baptistery; Brunelleschi had added a cupola to the cathedral; and Maso Finiguerra had led by his niello work to the discovery of copperplate engraving. It was in the 15th century that Bernardo Cennini introduced the art of printing into Florence. Filippino Lippi, Fra Bartolommeo and his friend Mariotto Albertinelli, Baccio d'Agnolo, Baldovinetti, Sandro Botticelli, the Ghirlandai, the Peselli, Benedetto da Rovezzano and Benedetto da Majano, Mino da Fiesole, Andrea Verocchio, and Leonardo da Vinci were the precursors, and some of them the contemporaries, of Michelangelo, the glory of his fellow citizens. With Andrea del Sarto and Raphael—who, though from Urbino, painted some of his finest works in Florence—painting reached its highest perfection. Among the men of literature were Boccaccio, Guicciardini, Macchiavelli, Poliziano, Marsilio Ficino, and Pico della Mirandola. Lorenzo's eldest son Piero succeeded to his honors; his second son Giovanni, already a cardinal, became afterwards Leo X., and his youngest son Giuliano, duke of Nemours, perhaps the only virtuous man among the Medici, died young.

When Charles VIII. of France was invited by Lodovico il Moro, lord of Milan, into Italy, Piero de' Medici, to conciliate the goodwill of the French king, visited him in his camp, and offered to yield the fortresses of Tuscany into his hands. On Piero's return to Florence he found himself condemned as a traitor, and had to escape from the city, followed by the rest of his family. Charles VIII. entered Florence in 1494, intending to restore the Medici, but the signory refused to comply with his request, and when the king, affecting to play the part of a conqueror in a vanquished city, dictated terms which he expected the Florentines to accept, Piero Capponi, one of that family of staunch republicans, tore the obnoxious paper in his presence. Charles angrily declared he would summon his troops by the call of the trumpet. "And we," replied Capponi, "will sound our bells"—the old war signal of the Florentines. Charles was forced to yield, but still lingered in Florence, until Savonarola, whose courage and sacred character appear to have overawed even this proud monarch, went to him and bade him begone. The influence of the "Frate" daily increased as well as the number of his followers; and eager to restore a free constitution to Florence, which he believed could only exist with virtue in her citizens, he persuaded the signory to call a grand council or parliament of the people. Charles VIII. had restored independence to Pisa, but the Florentines were eager to recover possession of that city, and since Pisa was the ally of Pope Alexander VI., the Borgia of infamous memory, and the greatest enemy of Savonarola, the "Frate" sanctioned the act. Piero Capponi perished during the course of this short war, and the Medici made a fresh attempt to re-enter Florence. The tide of popular favor was turning against Savonarola; step by step he lost ground with the people, till after a violent tumultuary attack on his convent of St. Mark in 1498, he was dragged to prison, torture, and execution.

Early in the 16th century Louis XII. of France having entered Italy to claim the duchy of Milan, by right of his grandmother Valentina, a Milanese princess, Pope Julius II., who had placed himself at the head of the league to drive him from the country, insisted on the Florentines joining the enemies of the French king and recalling the Medici. Piero had met his death by accidental drowning, but his son Lorenzo, duke of Urbino, returned to Florence, and after a short life of vicious indulgence, died in 1519, leaving an infant daughter, Catharine, afterwards married to Henry II. of France. Two illegitimate scions of the family, Ippolito and Alexander, now occupied the Medici palace in Florence. Clement VII., also a Medici, who had succeeded Pope Julius, was at this time besieged in his castle of St. Angelo by the Constable Bourbon, general of the emperor Charles V.; and in the year 1527 Rome was taken and sacked, to the consternation of all Europe, whilst the party in Florence hostile to the Medici alone perceived a gleam of hope in the destruction of a Medicean pope. Niccolo Capponi, a weak though amiable man, was the leader of this party, and Clarice, the sister of Lorenzo of Urbino and wife of Filippo Strozzi, one of the most unprincipled of Florentine citizens, appealed to Niccolo for aid to drive out of Florence the two youths Ippolito and Alexander, whom she refused to accept as belonging to her family. Meantime Clement had been reconciled to the emperor, and both approached Florence with a large army. After enduring all the protracted sufferings of a siege, and after the gallant but vain attempts of the patriot Feruccio to relieve his fellow citizens, Florence fell by treachery into the hands of the enemy; the Medici entered the city in triumph, and Alexander was created its duke (1530). Ippolito died by poison, administered, it is supposed, by his cousin Alexander, who, after a reign rendered detestable by his vices, was murdered in his bed by his cousin Lorenzino, in 1537. Cosimo de' Medici, son of Giovanni delle Bande Nere, a brave soldier and captain of mercenary troops, and descended from Lorenzo the brother of Cosimo the "father of his country," succeeded to the dukedom. The conquest of Siena added to his wealth and power; and in 1569 the pope created him grand-duke of Tuscany. Though accused of the murder of two of his sons and of a daughter, Cosimo had the force of character and ability to command fear, if not respect, from the people over whom he tyrannized. He was a patron of art, and this hereditary taste was continued in his son the grand-duke Francis I. (1575).

The school of art founded by Michelangelo had degenerated into feeble exaggerations, without the genius of the great master. Giovanni Bologna and Benvenuto Cellini alone struck out new and original paths; and the elegance and grace of their works in bronze and marble still adorn the public places of Florence, eclipsing the clumsy productions of their contemporaries. Francis was married first to Johanna of Austria, and secondly to a beautiful Venetian lady, Bianca Capello, whose first husband was assassinated to make way for the grand duke. Francis and Bianca died on the same day, 1587, not without suspicion of having been poisoned by his brother and successor Ferdinand, who resigned a cardinal's hat for the dukedom, and married Princess Christina of Lorraine. A double alliance was formed with France by the union in marriage of his niece Maria de' Medici, daughter of Francis, with King Henry IV. Cosimo II. succeeded Ferdinand in 1609. The day of his accession Galileo Galilei discovered the satellites of Jupiter, which, in compliment to the young sovereign, he named "Stelle Medicei." See GALILEO.

Ferdinand II. was still a child when he ascended the throne in 1621. He married Vittoria della Rovere, heiress of Urbino; and though her lands were claimed by the church, she brought a rich dowry to Florence. Ferdinand and his brother Cardinal Leopold added greatly to the art treasures in the galleries, and founded academies of art and science. Cosimo III., who succeeded in 1670, was a narrow-minded bigot, whose marriage with a gay young princess of the court of Louis XIV. of France ended in separation. He died in 1713, leaving one son, Gian Gastone, whose mild character, aversion to the punishment of death, and abolition of oppressive taxes made him popular with his subjects. Commerce, industry, and agriculture flourished during the reign of this last of the Medici. At his death in 1737 he left no male heirs to the throne. Tuscany had been already assigned by a European agreement —the celebrated Pragmatic Sanction—to Francis duke of Lorraine in compensation for his duchy, which had been annexed to France. In 1753 an edict gave Tuscany to the second son of Francis and the empress Maria Theresa; and two years later, on the death of his father, Pietro Leopoldo of Austria arrived in Florence to take possession of the throne. His short reign marked a new era of progress and reform. The Inquisition was abolished, privileges set aside, and plans proposed for draining and colonizing the Maremma. In 1790 Leopold was called to Vienna to succeed his brother Joseph II. as emperor, and left his younger son Ferdinand III. grand-duke of Tuscany. By an article of the Pragmatic Sanction, Tuscany had been declared a separate and independent sovereignty; therefore, when, after the outburst of the French Revolution, the emperor Francis II. claimed the assistance of a Tuscan army to restore the Bourbons in France, the great minister Fossombroni refused, declaring that Tuscany was on terms of peace and amity with the French republic. But in 1796 Ferdinand, yielding to the importunity of the court at Vienna, joined in the war against France, and two years later Florence was occupied by a French army. The first consul, Napoleon Bonaparte, conquered Tuscany, and whilst Ferdinand renounced his rights on condition of a compensation in Germany, one of the Bourbons of Parma was placed on his throne as king of Etruria. Tuscany was annexed to the French empire in 1808, but in 1809 the grand-duchy was restored in favor of Eliza Bonaparte Bacciochi, sister of the emperor Napoleon.

Her reign lasted only five years, and after Napoleon had been exiled to Elba, Ferdinand resumed his sovereignity. On this occasion an Austrian, Prince Rospigliosi, was sent to Florence to announce his arrival, and in his proclamation he declared Tuscany to be an inheritance and patrimony of the imperial house of Austria. The vain attempt of Lombardy in 1820 to shake off the Austrian yoke, an attempt in which the crown prince of Piedmont, Carlo Alberto, was secretly implicated, ended in the incarceration of some of the noblest Italian patriots in Austrian fortresses for a period of from 16 to 20 years. It was vain for Fossombroni to protest, and declare that the Tuscan government did not require Austrian soldiers to play the masters; Austrian soldiers arrived to occupy Tuscany as well as the other Italian states, and the aulic counsellor Menz wrote to Prince Metternich that "the Tuscan Government, led to reflect on its dangers, had assumed a firmer attitude, and constituted a more active and vigilant police, and, at all events, the respect inspired by Austrian bayonets placed at the gates of Tuscany were sufficient to dispel revolutionary ideas." Ferdinand died in 1833, and was succeeded by his son Leopold II., who had married a Neapolitan princess. Alarmed by the revolutionary movements of 1847, Leopold, like other Italian princes, granted his people a constitution, but when they further demanded to be led against the Austrians, to assist in driving the foreigner from Italy, he reluctantly permitted the Tuscan army, chiefly consisting of young volunteers, to depart. The enthusiastic youths who fought for the independence of their country displayed unwonted valor at Curtalone and Montanara; but the grand-duke signified his displeasure by withdrawing titles and pensions from even the surgeons who attended the wounded on the field of battle. Among the liberals in Florence who had long been seeking an opportunity to shake off foreign interference in the government of their country, were men of the greatest moderation and virtue,—Baron Bettino Ricasoli, the Marchese Cosimo Ridolfi, the poets Niccolini and Giusti, Salvagnoli, the Marchese Neri Corsini, and the Marchese Gino Capponi, the last of that family illustrious for virtue, for genius, and for patriotism.[1] The grand-duke, who either shared the principles of his family, or had not courage to place himself at the head of the distinguished men who coincided with the view of the Piedmontese minister Cavour, invited Austrian troops in 1850 again to occupy his dominions, and though Leopold affected to submit to necessity, the Austrian general declared he would not have come uninvited. This occupation lasted six years, during which time the power of life and death of Tuscan subjects was delivered into the hands of the Austrian commanders. When Victor Emmanuel, king of Piedmont and Sardinia, with the assistance of France, made war against Austria for the independence of Italy in 1859, a vain hope was still entertained that Leopold would have consented to unite his army with that of Piedmont; but the proclamation of war went forth without a sign from Tuscany. On the 27th April, 1859, the Tuscan troops unanimously declared their intention to throw down their arms unless they were allowed to join the War of Independence. The liberals insisted on the abdication of Leopold in favor of his son, and on an offensive and defensive alliance with Piedmont. Leopold declined these proposals, and quitted Florence with his family, amidst the silence of the assembled multitudes, never to return.

The following year Victor Emmanuel entered Florence, which in 1865 became the capital of his kingdom of Italy. It was not until 1870 that the hopes of the Florentines were disappointed, and the seat of government was transferred to Rome.

See the histories of the Florentine Republic by Gino Capponi, Atto Vanucci, T. A. Trollope, and Henry Napier; P. Villari's *Memoirs of Savonarola,* translated by Leonard Horner, etc. (A. S. H.)

FLORENCE, of Worcester, an English chronicler who lived during the end of the 11th and beginning of the 12th century. Nothing more is known of him than that he was a monk of Worcester, that he had a great reputation for learning, and that he died on the 5th June, 1118. His *Chronicle* begins with the creation of the world and ends with the year of his death. The earlier part is compiled from the Chronicle of Marianus Scotus, and the greater part of that which relates to English history is a translation from the Saxon Chronicle; but as he approaches his own times the independent value of his work increases, and in regard to contemporary events he is one of the most valuable of existing authorities. The Chronicle of Florence was continued from 1118 to 1141 by an anonymous writer.

An edition of the *Chronicle* was published at London in 1592, and another at Frankfort in 1601. It is also included in the *Collection of Historians,* edited by order of the Records Commission; and a translation with notes by Thos. Forester is contained in Bohn's *Antiquarian Library.*

FLORES, also called Endeh and Mangeraai, an island of the East Indian Archipelago belonging to the residency of Timor. It lies in a line with Java, between Sumbava on the west and Timor on the east, and stretches from 8° 3′ to 9° 59′ S. lat., and from 119° 49′ to 123° 1′ E. long. It is about 230 miles long, and from 20 to 40 broad, and its area is estimated at about 8900 square miles. Like most of the islands of the archipelago, it is both mountainous and volcanic, among the loftier summits being Ombuu Romba or Gunong Keo, 9054 feet in height; Lobetabi, or in a corrupted form, Lovotivo, 7115; Ombuu Soro or Gunong Rokka, 6557; and Larantuka or Ilimandiri, 5180. The interior is very partially explored, though the forests are neither so dense nor so extensive as in Borneo or Celebes. Besides amber, which is found on the coast, the mineral products consist of sulphur, pumice-stone, copper, and a little iron and gold. Sandal-wood, rice, wild cinnamon, and birds' nests are the most important articles of export, giving rise to a considerable trade with Celebes, Timor, Batavia, and Singapore. The inhabitants are mainly of Malay origin, and the language appears to be akin to that of Bima. There are considerable settlements of Buginese and Wadjorese. Portugal lays claim to certain portions of the island, but practically it is all under Dutch supremacy. Christianity has been introduced by the Portuguese on the east coast, and the converts are visited from time to time by priests from Timor.

See P. J. Veth, "Het eiland Flores," in *Tijdschrift voor Nederl. Indië,* 1855; E. Francis, *Herinneringen uit den levensloop van een Indisch ambtenaar,* 1856; S. Muller, *Bijdragen tot de Kennis van Timor.*

FLORES, the most westerly of the Azores. See Azores.

FLOREZ, Enrique (1701–1773), a Spanish historical scholar, was born at Valladolid in 1701. In his fifteenth year he entered the order of St. Augustine, professed theology at the university of Alcala, and published a *Carsus Theologiæ* in 5 vols. 4to (1732–1738). He afterwards devoted himself exclusively to historical studies. Of these, the first fruit was his *Clave Historial,* a work of the same class as the French *Art de Vérifier les Dates,* and preceding it by several years. It appeared in 1743, and passed through many editions. In 1747 was published the first volume of *La España Sagrada,* a vast compilation of local ecclesiastical history which obtained a European reputation, and of which 29 volumes appeared in the author's lifetime. It was continued after his death by Fathers Risco and Fernandez, and further additions have been made at the expense of the Spanish Government. The value of the work is considerably increased by the insertion of ancient chronicles and documents not easily accessible elsewhere. Florez was a good numismatist, and published *España Carpetana: Medallas de las Colonias,* in 2 vols. 4to (1757–1758). A third volume appeared in 1773. His last work was the *Memorias de las reynas Catolicas,* 2 vols. 4to (1770). Florez led a retired, studious, and unambitious life, and died at Madrid in May or August, 1773.

FLORIAN, the patron saint of Poland, was born at Zeiselmauer, Lower Austria, about the year 190. He served as a captain in the Roman army, and suffered death by drowning about the year 230, during the persecution of the Christians by the emperor Diocletian. His remains are said to have been buried on the site of the present Augustinian monastery at St. Florian near Linz, but were afterwards transferred to Rome. About 1183 a portion of them was presented to King Casimir of Poland, and from that time Florian became the patron saint of that country. He is represented as a warrior holding in his hand a vessel from which he pours out flames, and on this account his protection is often sought against fire. His day in the calendar is August 4.

FLORIAN, Jean Pierre Claris de (1755–1794), a French poet and romancist, was born at the château of Florian, near Sauve, in that part of Languedoc which now forms the department of Gard. His mother, a Spanish lady named Gilette de Salgues, died when he was quite a child, and the person who seemed to have had most influence on his early years was his grandfather, an old noble who had run through his estate. His uncle, the marquis of Florian, who had married a niece of Voltaire, introduced him at Ferney, and Florianet, as he was soon affectionately nicknamed, spent a pleasant time with the old dictator of French literature. In 1768 he became page in the household of the duke of Penthièvre at Anet, and throughout his life he was the object of the powerful patronage of that cultured nobleman. Having studied for some time at the artillery school at Bapaume he obtained from the duke a commission in a dragoon regiment, and in this capacity it is said he displayed a boisterous behavior as unlike as might be to what the reader of his works would naturally imagine. He afterwards left the army and became gentleman in ordinary. On the breaking out of the French Revolution he retired to Sceaux, but he was soon discovered and dragged to prison by the Parisian sans-culottes; and though his incarceration was not of long continuance, it so injured his health that he survived his release only a few months. His death took place on September 13, 1794.

Florian's first literary efforts took the shape of little comedies; but he first attracted attention by an epistle in verse entitled *Voltaire et le Serf du Mont Jura* and an eclogue called *Ruth,* which were crowned by the French

---

[1] Shortly before his death in 1876, at upwards of 80 years of age, he completed his admirable history of the Florentine Republic, *Storia della Repubblica di Firenze di Gino Capponi,* 2 tom., 8vo, 1875.

Academy in 1782 and 1783 respectively. In the latter year he also produced his *Galatée*, a professed imitation of the Galatea of Cervantes, and this was followed two years later by *Numa Pompilius*, an equally undisguised imitation of Fénelon's *Télémaque*, which as an educational work has proved only less popular than its prototype. In 1788 he became a member of the French Academy, and published *Estelle*, a pastoral of the same class as *Galatée*, which is reckoned one of the best of his works. Another romance, *Gonzalve de Cordoue*, preceded by an historical notice of the Moors, appeared in 1791, and his famous collection of *Fables* in 1792. After his death there appeared an unfinished treatment of the story of William Tell, to which he had devoted the leisure of his confinement, and an abridgment of Don Quixote, which, though far from being a correct representation of the original, had great success.

Florian was a professed imitator of Gessner, and his style has all the artificial delicacy and sentimentality of the Gessnerian school. Perhaps the nearest example of the class in English literature is afforded by Wilson's *Lights and Shadows of Scottish Life*. He is least affected in his fables, his comedies, and some of his minor tales. Among the best of the fables are reckoned "the Monkey showing the Magic Lantern," "the Blind Man and the Paralytic," and "the Monkeys and the Leopard;" and *Les Deux Billets*, *Le Bon Père*, and *Le Bon Menage* are the best known of the comedies. In the latter he brought the arlequinades again into fashion, and raised them to a higher level. Florian's *Œuvres Complètes* appeared at Paris in 16 volumes, 1820; his *Œuvres inédites* in 4 volumes, 1824. Didot published an edition in 24 volumes, Briand another in 13, and Jauffret a third in 12. The editions of some of the more popular works are extremely numerous.

See "Vie de Florian" prefixed to his *Œuvres posthumes*; A. J. N. de Rosny, *Vie de Florian*, Paris, An V.; Jauffret and Lacretelle, *Eloge de Florian*, 1812; Sainte-Beuve, *Causeries du lundi*, t. iii.

Plate II.

FLORIDA, the most southern of the United States of America, is a large promontory extending southwards into the Atlantic ocean, its southern and western coasts forming in part the northern and eastern shore line of the Gulf of Mexico.

The name of Florida was in the 16th and early part of the 17th century indefinitely applied to the territory now lying south of Virginia. By its charter the southern boundary of Carolina was fixed at the 29th parallel, thus including about one half of the present State of Florida. In 1738 the stipulated northern boundary of Florida was a line drawn due west from the mouth of the St. John's River (called by the Spaniards San Juan) to the little river Vasisa, cutting off all upper or continental Florida. At the time of its cession by Spain to Great Britain in 1763, the territory of Florida extended as far west as the Mississippi River, including portions of the present States of Alabama, Mississippi, and Louisiana. The present boundaries are comprised between 24° 30′ and 31° N. lat., and 80° and 87° 45′ W. long.

Florida makes the southern boundary of the State of Georgia, and in part that of Alabama, from which it is separated on the north-west by the river Perdido. The Atlantic washes its eastern, and the Gulf of Mexico its southern and western coasts, constituting a sea-board of more than 1000 miles. On the south-east it is separated from the Bahamas by the Straits of Florida. It points towards Cuba on the south, Havana being about 110 miles from Key West. Its entire length from Perdido river to Cape Sable is about 700 miles, its mean breadth 90 miles. The estimated area of Florida is 59,268 square miles, or 37,931,520 acres, of which 2,373,541 acres were in 1870 included in farms. The population in 1870 was 187,748.

The peninsula proper terminates on the south in Cape Sable; but a remarkable chain of rocky islets, called the Florida Keys, begins at Cape Florida on the eastern shore, extends south-westerly nearly 200 miles in a direction generally conforming with that of the coast, and ends in the cluster of sand-heaped rocks known as the Tortugas, from the great number of turtle formerly frequenting them. South of the bank on which these Keys rise, and separated from them by a navigable channel, is the long, narrow, and dangerous coral ridge known as the Florida Reef. This group of keys and reefs is washed on the south by the constant current of the Gulf Stream. The most important of the keys is Key West, a nautical corruption of *Cayo Hueso* or Bone Key, which name originated in the great number of bones found on the island by the Spaniards, supposed to be those of the aboriginal inhabitants. The island was long the haunt of smugglers and pirates, but is now a busy and thriving place, and one of the most important naval stations possessed by the United States, on account of its commanding situation at the entrance of the most frequented passage into the Gulf of Mexico, as well as its nearness to Havana, Kingston, and other important ports of the West Indies, belonging to European powers.

The Gulf Coast of the State is intersected by numerous bays, among which are Pensacola, Choctawhatchee, St. Andrew's, Appalachicola, Appalachee, Tampa, Charlotte, Ponce de Leon or Chatham, and Florida Bays, the last lying between the Keys and mainland. The chief rivers are St. John's, navigable about 100 miles for vessels of moderate draught, and emptying into the Atlantic after a northerly course of 300 miles; Indian River, a long narrow lagoon on the eastern coast, which it is proposed to unite by a canal with the St. John's; the Suwanee and Ockloconee, which rise in Georgia and flow into the Gulf of Mexico; the Appalachicola, formed by the Chattahootchee and Flint rivers, and emptying into the bay of the same name; Choctawhatchee, Escambia, and Perdido, also flowing into the Gulf. The St. Mary's makes for some distance the northern boundary of the State. Florida has also numerous lakes, some of which are navigable. Lake Okeechobee, in the Everglades, is about 40 miles long and 30 broad.

Surface and Soil.—The surface is generally level, the greatest elevation being not more than 300 feet above the sea, although old maps represent it as mountainous. The most remarkable feature is the immense tract of marsh filled with islands in the southern part of the State, called the Everglades, and by the Indians "grass-water." Between the Suwanee and Chattahootchee the country is hilly; the western portion of the State is level. De Bow designates the lands as high-hummock, low-hummock, swamp, savanna, and pine. The soil is generally sandy, except in the hummocks, where it is intermixed with clay. These hummocks vary in extent from a few to thousands of acres, and are found in all parts of the State. They are usually covered with a heavy growth of red, live, and water oak, magnolia, pine, and dogwood. When cleared they afford desirable openings for cultivation. The savannas are rich alluvions on the margins of streams or lying in detached tracts, yielding largely, but requiring ditching and dyking in ordinary seasons. In the "barrens," as the pine forests are called, the soil is very poor, and thickly overgrown with pine and cypress. The district comprised in the Everglades is impassable during the rainy season, from July to October. It is about 60 miles long by 60 broad, covering most of the territory south of Lake Okeechobee, or Big-water. The islands with which this vast swamp or lake is studded vary from one-fourth of an acre to hundreds of acres in extent. They are generally covered with dense thickets of shrubbery or vines, occasionally with lofty pines and palmettos. The water is from 1 to 6 feet deep, the bottom being covered with a growth of rank grass. The vegetable deposit of the Everglades is considered well adapted to the cultivation of the banana and plantain. Another remarkable feature of Florida are the subterranean streams which undermine the rotten limestone formation, creating numerous cavities in the ground called "sinks." These are inverted conical hollows, or tunnels, varying in extent from a few yards to several acres, at the bottom of which running water often appears.

A most remarkable spring, situated 12 miles from Tallahassee, has been sounded with 250 fathoms of line before finding bottom. The outflow forms a beautiful lake, transparent and cold as ice even in the hottest weather. The great sink of Alachua county is a subterranean passage by which the waters of the Alachua savanna are supposed to discharge themselves into Orange Lake. In fact, the geological structure of the State is remarkable, much of its surface seeming a crust through the openings of which underground lakes and rivers force their way.

Towns and Harbors.—Notwithstanding the great extent of its sea-coast, Florida has few good harbors. Besides being a naval station, Key West is a place of considerable importance. Pensacola, Appalachicola, St. Mark's, Cedar Keys, Tampa, and Charlotte on the Gulf, and Fernandina and St. Augustine on the Atlantic coast, are the principal

ports. Of these the harbors of Pensacola and Fernandina are the best. The cities of Florida are Jacksonville, population in 1870, 6912; Pensacola, 3347; Tallahassee, the capital, 2023; and St. Augustine, 1717. Jacksonville, on St. John's River, is a flourishing city, much resorted to by invalids from the northern States on account of the salubrity of its climate. Fernandina, the eastern terminus of the railway which crosses the State to Cedar Keys, on the Gulf of Mexico, has 1722 inhabitants.

Climate.—Florida, except in the vicinity of the swamps, possesses one of the most equable and agreeable climates of the continent. Occupying as it does a situation between the temperate and tropical regions, it enjoys exemption from the frosts and sudden changes of the one and the excessive heat of the other. The mercury, however, sometimes falls to the freezing point, and great damage is done to the orange plantations. The winter climate of the Gulf coast is more rigorous than that of the Atlantic. The seasons partake of the tropical character, winter being distinguishable by copious rains. Statistics show the State to be one of the healthiest, if not the healthiest, of the United States, and its resident population is largely increased in the winter months by invalids from the North, seeking a more genial clime. Jacksonville, St. Augustine, and Key West are preferred by this class of visitors, who are every year becoming more numerous. The mean winter temperature as observed at Key West was slightly less than that of Havana; while for the months from July to November it was about the same. Besides the advantage of its climate, the semi-tropical character of Florida offers a grateful and striking change of scene to the health-seeker, who leaves the bare forests and frozen streams of New England for a country teeming with luxuriant vegetation and strewed with flowers.

Products.—The productions of Florida are of an essentially tropical character: cotton, tobacco, rice, sugar-cane, arrow-root, hemp, flax, coffee, and the cocoa-nut flourish there. The climate is also favorable to the cultivation of the silk-worm and for the cochineal insect. Oranges, bananas, lemons, limes, olives, grapes, pine-apples, grow abundantly, and are of exquisite flavor. Indian corn, sweet potatoes, beans, peas, and such products of a more northern climate as Irish potatoes, barley, buckwheat, hops, etc., are also raised. The cultivation and export of oranges and other fruits have grown to be a considerable source of wealth to the State; and the manufacture of cigars, especially at Key West, is becoming an important industry. The pasturage afforded by the savannas is excellent, cattle requiring little or no attention from their owners, and no housing in winter. Game and fish abound in every part of the State. Deer, wild turkeys, partridges, geese, ducks, and other small game are in all the forests and about all the lakes, rivers, and swamps; green turtle, oysters, sheep's-head, red-fish, mullet, etc., are found on all the coasts, and freshwater fish in all the inland waters. Magnificent sponges are gathered along the reefs, and form a considerable item of trade. Cotton, rice, sugar, tobacco, lumber, fish, and fruits may be considered the most valuable products. From selected statistics, compiled by the United States Government, it appears that Florida produced in 1870—Indian corn, 2,225,056 bushels; oats, 114,204 bushels; cotton. 39,789 bales; wool, 37,562 ℔; rice, 401,687 ℔; cane, 553,192 galls.; Irish potatoes, 10,218 bushels; sweet potatoes, 789,456 bushels; peas and beans, 64,846 bushels; honey, 150,854 ℔. Florida cotton is grown almost exclusively in the northern group of counties, but the State is capable of producing the celebrated Sea Island variety, the cultivation of which was formerly confined to a few islands on the coasts of South Carolina and Georgia. Appalachicola, formerly a considerable shipping port for cotton, has been superseded by Fernandina on the Atlantic. The crop of 1876–77 is reported at 34,303 bales, of which 11,214 was Sea Island; but it should be stated that this computation includes only shipments from Florida outports, there being no data whence to estimate accurately the quantity going to ports out of the State by rail. The same remark will apply to the quantity of wool exported.

The wool grown in Florida is long-stapled, of medium and coarse grades; little attention being as yet given to producing fine wools. In 1878 the flocks had increased to 56,500 head, yielding 200,000 ℔ of wool.

In 1874 Gadsden county produced on 327 acres planted 216,000 ℔ of tobacco, of excellent quality, valued at $44,000. East and South Florida rely mainly upon fruit culture. Florida is said to be the only section of the Union where the orange can be grown to any extent with success. There is no fear of winter-killing south of Pilatka. The quality of the fruit and the excellent condition in which it reaches the northern markets render this a most profitable crop.

The forests of Florida form no inconsiderable source of wealth. The live-oak, so valuable in shipbuilding, abounds, also the other varieties of oak, swamp cypress, hickory, pine, magnolia, dogwood, and laurel. The palma christi (castor-oil bean) becomes here a large tree; on the islands and keys boxwood, satinwood, mastic, and lignum-vitæ grow abundantly. The pine is found from Cape Sable to near Indian River. In addition to fruit-bearing species, the pimento, coffee, pepper, clove, and other spice trees and shrubs may be successfully cultivated.

From the official sources of information it appears that in 1870 the value of the live stock on farms was $5,212,157. The number of horses was 11,902; mules and asses, 8835; milch cows, 61,932; draught and other cattle, 322,701; sheep, 26,509; swine, 158,908. Florida also produced 100,989 ℔ butter. These numbers will be largely increased by the census of 1880.

Manufactures.—These are unimportant, and are chiefly confined to flour and grist mills, lumber mills, and establishments for the manufacture of sugar and molasses, their total value in 1870 being $4,685,403. Agriculture and commerce are the chief resources of the State,—the export of its fibrous products, cereals, fruits, fish, live-oak and other timber, giving employment to a considerable tonnage. Among the mineral productions may be named amethyst, turquoise, lapis-lazuli, ochre, coal, and iron-ore.

Trade.—The coasting trade employs many steamers and sailing craft, plying chiefly between Florida ports and Savannah, Baltimore, Philadelphia, and New York. Pensacola and Appalachicola are naturally points of shipment for southern Alabama and south-western Georgia. The bulk of foreign merchandise reaches the State from northern ports instead of by direct importation. Key West shows much the largest tonnage of vessels entering or clearing, St. John's and Fernandina following in the order named. Shipbuilding is carried on at all the ports, the vessels usually being of small burden, for coast traffic.

Railways.—In 1876 there were only 484 miles of railway in Florida. The Jacksonville, Pensacola, and Mobile railroad extends west from Jacksonville to Chattahootchee, and is the longest in the State. Lateral lines connect this line with the Georgia system by a branch from Live Oak due north to Dupont, and with St. Mark's on the Gulf by a branch south from Tallahassee. The Atlantic, Gulf, and West India Transit Company's line extends from Fernandina on the Atlantic to Cedar Keys on the Gulf, distance 155 miles. The Pensacola and Louisville road extends from Pensacola north to a junction with the Mobile and Montgomery (Alabama) railroad, 45 miles. The St. John's River line crosses from St. Augustine to Tocoi on the St. John's, 14 miles.

Administration.—The government of Florida is similar to that of the other States of the American Union. The executive power is vested in a governor elected by the people every four years. The legislative power is represented by a senate elected for four years, and a house of representatives or assembly chosen for two years, both by popular vote. The judiciary consists of a supreme court, having one chief and two associate judges, who hold three annual sessions in Tallahassee; there are also seven circuit besides other inferior courts. Florida has two members in the national house of representatives, and has therefore (with the two senators to which each State is entitled) only four votes in the electoral college. The State is divided into 39 counties, viz., Alachua, Baker, Bradford, Brevard, Calhoun, Clay, Columbia, Dade, Duval, Escambia, Franklin, Gadsden, Hamilton, Hernando, Hillsborough, Holmes, Jackson, Jefferson, Lafayette, Leon, Levy, Liberty, Madison, Manatee, Marion, Monroe, Nassau, Orange, Polk, Putnam, St. John's, Santa Rosa, Sumter, Suwanee, Taylor, Volusia, Wakulla, Walton, Washington.

Education.—Florida has neither college nor university, although an agricultural college has been incorporated; the financial condition of the State and people after the close of the great civil war has greatly retarded educational development. There is no public library of 10,000 volumes in the State. In 1876, out of a school population numbering 74,828 persons, the number actually attending public schools was only 26,052. The total expenditure for educational purposes was $2,126,541. The slow development of education in the State may also be attributed to the numerous colored population (91,384 in 1870) formerly held in slavery, which is wholly engaged in tilling the soil and kindred pursuits. Since the war Florida has received large accessions to its population from other States, and is undergoing changes which will, it is believed, ultimately lead to its taking a higher rank in the Union. In 1870, there were in the State 23 newspapers and periodicals, with a total circulation of 10,545. The total number of religious organizations was 420, having 390 places of worship, and property valued at $426,520.

History.—The history of Florida is interesting. The various attempts at colonization by Europeans of which we have authentic accounts go farther back than in any other part of the North American continent, preceding the efforts of the French in Canada, the English in Virginia, and even of the Spaniards themselves in Mexico. St. Augustine is the oldest settlement founded by Europeans, not only of the United States, but of North America, and still shows traces of Spanish occupation two centuries ago. Remains of fortifications, roads, etc., are found between the Suwanee and Chattahootchee. In 1512, seven years before the invasion of Mexico by Cortes, Juan Ponce de Leon discovered the mainland of Florida on Easter Sunday, *Pascha Floridum*, the supposed derivation of the name. The discoverer landed at a place called the Bay of the Cross, took formal possession, and planted a stone cross in sign of the jurisdiction of Spain. He continued his explorations in the interior and along the coast for some months before sailing to Spain. The following year he was named governor of and received permission from Ferdinand to colonize the "Island of Florida." His efforts, however, proved unsuccessful. The place of his original landing is supposed to be a few miles north of Saint Augustine.

The next effort at colonization was the disastrous one of Pamphilo de Narvaez in 1528. He sailed from Cuba with 400 men, landed in the bay of Pensacola, and remained in the country nearly six months, when he re-embarked and perished in a tempest near the mouth of the Mississippi. Four survivers of this expedition succeeded, after incredible hardships, in reaching Mexico.

Hernando de Soto landed on May 30, 1539, at what is now Tampa Bay, called by the Spaniards "Spiritu Santo." De Soto believed Florida a new El Dorado. He had the title of *Adelantado*, or president, from the emperor, and undertook the conquest at his own expense. He passed the first winter in the country of the Appalachians, east of Flint River. After a sanguinary conflict with the natives, who opposed his advance into the interior, and the loss of many men by disease, De Soto reached the Mississippi, where he died from fever while endeavoring to descend its banks to the mouth.

Réné Goulaine de Laudonnière, who had accompanied Jean Ribault in his expedition to Port Royal (1562), landed first at what is now St. Augustine, subsequently in the river St. John, called by him the "River of May," and built Fort Caroline in 1564. The colonists, who were Huguenots, were on the point of abandoning the settlement when reinforced by Ribault; but he had scarcely anchored when a Spanish fleet under Menendez appeared. Ribault made his escape for the moment. Soon after Menendez surprised and massacred the garrison of Fort Caroline, carrying out to the letter his barbarous order to "gibbet and behead all Protestants in those regions." In endeavoring to return to Fort Caroline, Ribault and his party also fell into the hands of Menendez, and shared the fate of their companions. The French were all hanged with the inscription affixed to them —"Not as Frenchmen, but as heretics."

Aviles de Menendez, referred to as exterminating the French settlement on the St. John, landed September, 1565, and laid the foundation of the town, named by him St. Augustine. Two years later a French expedition commanded by Dominique de Gourgues, seized two forts near the mouth of the St. John, and the important one of San Mateo, and in retaliation for the cruelty of Menendez hanged all his prisoners, "not as Spaniards, but as assassins." De Gourgues's head was demanded by the Spanish king, and he was for a time compelled to live in concealment. Menendez afterwards rebuilt San Mateo.

On the 28th of May, 1586, Sir Francis Drake, then returning from his memorable expedition to the West Indies, discovered a scaffold raised upon four high masts, evidently a look-out station, upon the Florida coast. No one in the fleet had any knowledge that the Spaniards possessed a place there. Drake therefore ordered the pinnaces to make a reconnaissance. Having entered an inlet they came to the fort St. Juan de Pinos, from which the garrison fled to St. Augustine; and on the approach of the English they also abandoned this place, which had the appearance of a prosperous settlement, with its council-house, church, and handsome gardens. The invaders destroyed the town and meditated an attack on St. Helena, twelve leagues further up the coast, but were deterred from want of a pilot to conduct them safely through the intricate and dangerous shoals. Drake pursued his voyage to Virginia, where the queen had commanded him to afford relief to Sir Walter Raleigh's newly planted colony.

The English colonists of Georgia and Carolina continued to wage war against the Spaniards in Florida. Governor Moore of South Carolina made an unsuccessful attempt on St. Augustine in 1702; and General Oglethorpe of Georgia besieged it in 1740 with the same result. Nearly a hundred years later, in 1837, the U. S. engineers found balls thrown by Oglethorpe in the moat of the old Spanish fortress. In 1763 Florida was ceded to Great Britain in return for Havana, captured by Albemarle the previous year. Most of the Spaniards left the country. Vigorous efforts were made by the British Government to promote settlement by liberal grants of land to settlers. Besides a large number of emigrants who came over from Europe, promising settlements were made under the patronage of Lords Rolle and Beresford and Governor Moultrie. In addition to these many royalists emigrated thither from Georgia and Carolina, on the breaking out of hostilities between Great Britain and her American colonies. Twenty years of British possession accomplished more in settling and improving Florida than two hundred years of Spanish rule.

In 1781 Don Bernardo de Galvez, Spanish governor of Louisiana, having previously taken Mobile, besieged and captured Pensacola, thus completing the conquest of West Florida. In 1783 Florida was ceded back to Spain, when the greater part of the English population, estimated at 25,000, left the province and passed into the adjoining States. Some unimportant military operations took place in 1814. In February, 1819, a treaty for the cession of Florida to the United States was concluded at Washington, and in 1821 was reluctantly ratified by the king of Spain, thus concluding a long and tedious negotiation. Possession was taken in July by General Jackson, who had been appointed governor of the Floridas by the Government at Washington. Immigration flowed in rapidly from the Southern States, the Bahamas, and even the North Atlantic States; but a great drawback to the prosperity of the newly acquired territory was found in the determined resistance of the warlike nation of Seminole Indians to the encroachments of the whites upon their hunting-grounds. A resolution on the part of the United States Government to remove these Indians led to the long and bloody struggle known as the Seminole War, in which for seven years the Indians successfully defied every effort to subdue them, retreating into the fastnesses of the Everglades when closely pressed. Osceola, chieftain of the Seminoles, having been captured by treachery, the war ended in 1842. The remnant of the Indians were removed beyond the Mississippi, and in three years after their expulsion (1845) Florida was admitted into the Union as a State.

On the 10th January, 1861, Florida, by a convention assembled on the 3d, seceded from the Union. Fort Marion and the arsenals at St. Augustine and Chattahootchee were seized on the 7th, the forts and dockyards at Pensacola on the 12th, except Fort Pickens, on Santa Rosa island, which was held by the United States forces. Not being within the line of great military operations, the conflicts between the Federal and Confederate forces were of minor importance. Fernandina, Jacksonville, and St. Augustine fell into the hands of the national forces early in 1862. Pensacola was reoccupied by them the same year. In April, 1865, President Johnson, by a proclamation, declared the restrictions on commercial intercourse with Florida removed; in July William Marvin was named provisional governor. A State convention assembled in October at Tallahassee which repealed the ordinance of secession.

Civil government was practically resumed the following year by the election of State officers and a legislature. A subsequent State convention met at Tallahassee, January 20, 1868, to form a new constitution, which was ratified by the people in May, a legislature and State officers being chosen at the same election. The State having complied with the enactments of Congress relative to reconstruction resumed its place in the Union. In 1876 the election of Rutherford B. Hayes, republican, as president of the United States, over Samuel J. Tilden, democrat, was determined by the electoral votes of Florida and Louisiana, which by a decision of the extraordinary commission created by Congress were counted for the former. (S. A. D.)

FLORIDA-BLANCA, DON JOSE MONINO Y REDONDO, COUNT OF (1728–1808), Spanish statesman, was born at Murcia in 1728. He was the son of a notary, and received a good education, which he completed at the university of Salamanca, especially applying himself to the study of law. For a time he followed the profession of an advocate, and acquired a high reputation. A more public career was opened to him by the marquis of Esquilache, then chief minister of state, who sent him ambassador to Pope Clement XIV. Successful in his mission, he was soon after appointed by Charles III. successor to his patron, and his administration was one of the most brilliant Spain had ever seen. He regulated the police of Madrid, reformed many abuses, projected canals, established many societies of agriculture and economy, and many philanthropical institutions, and gave encouragement to learning, science, and the fine arts. Commerce flourished anew under his rule, and the long-standing disputes with Portugal about the South American colonies were settled. He sought to strengthen the alliance of Spain with Portugal by a double marriage between the members of the royal houses, designing by this arrangement to place ultimately a Spanish prince on the throne of Portugal. But in this he failed. His attacks on Algiers in 1775, and on Gibraltar in 1782, cost Spain the loss of nearly 80,000 men. He dealt a heavy blow to the Cortes, prevailing upon them by various forms of bribery, and by sowing dissension among the members, to proclaim the heir to the throne without making the customary assertion of their privileges. He retained his office for three years under Charles IV.; but in 1792, through the influence of his enemies, he was dismissed and imprisoned in the castle of Pampeluna. Here he was saved from starvation only by the intervention of his brother. He was afterwards allowed to retire to his estates, and remained in seclusion till the French invasion of 1808. He was then called by his countrymen to take the presidency of the central junta. But his strength failed him, and he died at Seville, November 20 of the same year. He left several short treatises on jurisprudence.

FLORIO, GIOVANNI (about 1552–1625), lexicographer and translator, was born in London about 1552. He was of Tuscan origin, his father and mother being Waldenses who had fled from persecution in the Valtelline and taken refuge in England. The family left England on the accession of Queen Mary, but returned after her death. The son resided for a time at Oxford, and was appointed, about 1576, preceptor to the son of Barnes, bishop of Durham, then studying at Magdalen College. In 1578 Florio published a work entitled *First Fruits, which yield Familiar Speech, Merry Proverbs, Witty Sentences, and Golden Sayings* (4to). This was accompanied by *A Perfect Induction to the Italian and English Tongues*. The work was dedicated to the earl of Leicester. Three years later Florio was admitted a member of Magdalen College, and became a teacher of French and Italian in the university. In 1591 appeared his *Second Fruits, to be gathered of Twelve Trees, of divers but delightsome Tastes to the Tongues of Italian and English men;* to which was annexed the *Garden of Recreation, yielding six thousand Italian Proverbs* (4to). His Italian and English dictionary, entitled *A World of Words*, was published in folio in 1598. After the accession of James I., Florio was named French and Italian tutor to Prince Henry, and afterwards became a gentleman of the privy chamber and clerk of the closet to the queen, whom he also instructed in languages. His last work, and that by which he has been most known, was his translation of Montaigne's *Essays*, published in folio in 1603, and dedicated to the queen. Special interest attaches to this translation from the circumstance that of the several copies of the first edition in the British Museum library one bears the autograph of Shakespeare and another that of Ben Jonson. It has been suggested that Florio is satirized by Shakespeare under the character of Holofernes, the pompous pedant of *Love's Labor's Lost.* He is characterized by Wood, in *Athenæ Oxonienses*, as a very useful man in his profession, zealous for his religion, and deeply attached to his adopted country. When the plague raged in London in 1625, Florio sought escape from it by retiring to Fulham; but he was there seized and carried off by it in the autumn of the same year.

FLORIS, FRANS, or more correctly Frans de Vriendt called Floris (1520–1570), was one of a large family trained to the study of art in Flanders. Son of a stone-cutter, Cornelis de Vriendt, who died at Antwerp in 1538, he began life as a student of sculpture, but afterwards gave up carving for painting. At the age of twenty he went to Liége, and took lessons from Lambert Lombard, a pupil of Mabuse, whose travels in Italy had transformed a style truly Flemish into that of a mongrel Leonardesque. Following in the footsteps of Mabuse, Lambert Lombard had visited Florence, and caught the manner of Salviati and other pupils of Michelangelo and Del Sarto. It was about the time when Schoreel, Coxcie, and Heemskerk, after migrating to Rome and imitating the masterpieces of Raphael and Buonarroti, came home to execute Dutch-Italian works beneath the level of those produced in the peninsula itself by Leonardo da Pistoia, Nanaccio, and Rinaldo of Mantua. Fired by these examples, Floris in his turn wandered across the Alps and appropriated without assimilation the various mannerisms of the schools of Lombardy, Florence, and Rome. Bold, quick, and resolute, he saw how easy it would be to earn a livelihood and acquire a name by drawing for engravers and painting on a large scale after the fashion of Vasari. He came home, joined the guild of Antwerp in 1540, and quickly opened a school from which 120 disciples are stated to have issued. Floris painted strings of large pictures for the country houses of Spanish nobles and the villas of Antwerp patricians. He is known to have illustrated the fable of Hercules in ten compositions, and the liberal arts in seven, for Clæs Jongeling, a merchant of Antwerp, and adorned the duke of Arschot's palace of Beaumont with fourteen colossal panels. Comparatively few of his works have descended to us, partly because they came to be contemned for their inherent defects, and so were suffered to perish, partly because they were soon judged by a different standard from that of the Flemings of the 16th century. The earliest extant canvas by Floris is the Mars and Venus ensnared by Vulcan in the Berlin Museum (1547), the latest a Last Judgment (1566) in the Brussels gallery. Neither these nor any of the intermediate works at Alost, Antwerp, Copenhagen, Dresden, Florence, Léau, Madrid, St. Petersburg, and Vienna display any charm of originality in composition or in form. Whatever boldness and force they may possess, or whatever principles they may embody, they are mere appropriations of Italian models spoiled in translation or adaptation. Their technical execution reveals a rapid hand, but none of the lustre of bright coloring; and it is not too much to say that whilst Floris failed to acquire absolute mastery over design as improved by the Italians, he was equally devoid of the gifts which distinguish the earlier colorists of Flanders. Vasari justly praises the plates engraved by contemporaries from the drawings of Floris, but he adds that these plates would have been better had the skill of the draughtsman been more ably seconded by that of the engraver. A more temperate judgment will probably be that Floris owed much of his repute to the cleverness with which his works were transferred to copper by Jerome Cock and Theodore de Galle. Whilst Floris was engaged on a Crucifixion of 27 feet, and a Resurrection of equal size, for the Grand Prior of Spain, he was seized with illness, and died on the 1st of October, 1570, at Antwerp. His burial took place three days later in the cemetery of the Récollets.

FLORUS, a Roman historian, author of the *Epitome de Gestis Romanorum*, has by some writers been identified with the Lucius Julius Florus who lived in the time of Augustus, and to whom Horace addressed two of his epistles; but this position is hardly tenable, as Florus in the introduction to his history writes of the emperor Trajan as then reigning. By others he is, on account of certain similarities in style, identified with the Publius Annius Florus who lived in the time of Hadrian, and wrote a dialogue on the question whether Virgil was an orator or a poet, and the *Pervigilium Veneris*, an imitation of Horace's *Secular Hymn*. In some MSS. of the *Epitome*, the name of the writer is mentioned as L. Annæus Florus, in others as L. Julius Florus, in others L. Annæus Seneca, and in the Bamberg codex Julius Florus. If the historian be the same person as the poet and rhetorician, Julius Annæus must be regarded as a corruption of Publius Annius. The *Epitome* of Florus is compiled chiefly from Livy, and gives a condensed view of Roman history from the foundation of the city to the closing of the temple of Janus by Augustus. The details of geography and chronology are not always to be implicitly trusted; and the style is declamatory, and rather that of a panegyrist than of a critical historian. The best editions of the work are that of Titze, Prague, 1819, and that of O. Jahn, Leipsic, 1852. The latter has been revised by C. Halm, Leipsic, 1854.

FLOTSAM, Jetsam, and Ligan, in English law, are goods lost at sea, as distinguished from goods which come to land, which are technically designated *wreck*. "Jetsam is when goods are cast into the sea, and there sink and remain under water; flotsam is where they continue swimming on the surface of the waves; ligan is where they are sunk in the sea, but tied to a cork or buoy in order to be found again." Flotsam, jetsam, and ligan belong to the king in the absence only of the true owner. Wreck, on the other hand (*i.e.*, goods cast on shore), was by the common law adjudged to the king in any case, because it was said by the loss of the ship all property was gone out of the original owner. This singular distinction which treated goods washed ashore as lost, and goods on and in the sea as not lost, is no doubt to be explained by the primitive practice of plundering shipwrecks. See the article Wreck, for the law relating to that subject.

FLOUNDER (*Pleuronectes flesus*) is one of the most common Flat-fishes along the coasts of northern Europe, from the British Channel to Iceland. It is more partial to fresh water than any other Flat-fish, ascending rivers far beyond the reach of the tide, as, for instance, the Rhine as far as Cologne. It very rarely exceeds the length of twelve inches, and a weight of 1½ pounds.

FLOUR, Manufacture of. Flour is the grain of wheat reduced to powder, and separated from the outer husk or coverings in which the seed is enveloped. The name is also applied to the grain of other cereals, and to the farinaceous seed of pulses similarly treated, and it is used generally to indicate any finely powdered dry substance; but when the term is employed without any qualification, it invariably means wheaten flour. As preparations of flour form the staple food of all civilized communities of the West, the cultivation of wheat and the manufacture of flour are necessarily industries of the greatest magnitude and importance, rice being the only other grain which rivals (and which indeed possibly surpasses) wheat in the number of human beings it feeds.

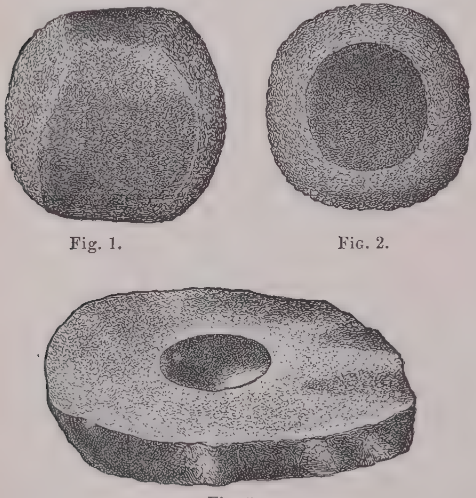

Fig. 1. Fig. 2.

Fig. 3.

Figs. 1–3.—Primitive Corn-crushers (from Keller's *Lake Dwellings*).

The cultivation of wheat was one of the earliest developments of human civilization, and there are not wanting evidences that in making use of the grain the primitive races submitted it to a coarse pounding or grinding, thereby reducing it to a state resembling the meal of the present day. From remains found on the sites of the ancient lake dwellings of Switzerland it is obvious that the original form of corn-crushing or mealing apparatus consisted of a roundish stone—generally very hard sandstone—about the size of a man's fist, with certain hollows or flattened surfaces on two opposite sides (figs. 1–3). The rounded outline of the stone worked and fitted into a corresponding cavity in another stone in which the grain to be crushed or pounded was placed. By the deepening of the cavity in the under stone and the addition of a wooden handle to the upper stone ball, would be formed the mortar and pestle; and in another direction, by fitting the upper stone for a motion of rotation within the cavity of the lower, the form of the quern would be produced, and the germ of the modern flour-mill elaborated. In early times, and indeed amid rude forms of society still, the preparation of meal and flour was a part of the domestic operations of preparing bread and otherwise cooking of food. At a period so remote as that of the patriarch Abraham it appears there was a distinction in the qualities of the flour or meal which could be produced, as Sarah was directed to "make ready quickly three measures of *fine* meal, knead it, and make cakes upon the hearth." There is much probability in the suggestion of Dr. Livingstone that the grinding apparatus used by Sarah was similar to that still used in Central Africa, and figured in the frontispiece of his *Zambesi and its Tributaries*. In that work the apparatus is thus described:—

> "The mill consists of a block of granite, syenite, or even mica-schist, 15 or 18 inches square, and 5 or 6 thick, with a piece of quartz or other hard rock, about the size of a half brick, one side of which has a convex surface, and fits into a concave hollow in the large and stationary stone. The workwoman kneeling grasps this upper millstone with both hands, and works it backwards and forwards in the hollow of the lower millstone, in the same way that a baker works his dough when pressing it and pushing it from him. The weight of the person is brought to bear on the movable stone, and while it is pressed and pushed forwards and backwards, one hand supplies every now and then a little grain, to be thus at first bruised, and then ground on the lower stone, which is placed on the slope, so that the meal when ground falls on to a skin or mat spread for the purpose. This is, perhaps, the most primitive form of mill, and anterior to that in Oriental countries, where two women grind at one mill, and may have been that used by Sarah of old when she entertained the angels."

That the two forms of grinding apparatus were familiar to the nations of antiquity is obvious from the allusions made to both in the Pentateuch. In the book of Numbers (xi. 8) we read that the Israelites gathered manna, "ground it in mills, or beat it in a mortar;" and again in Deuteronomy (xxiv. 6) there is an injunction that "no man shall take the nether or the upper millstone to pledge, for he taketh a man's life to pledge." Numerous other allusions to mills, mortars, and the grinding of corn are scattered throughout Scripture, from which it is made clear that the grinding of corn was, among the Hebrews, a domestic employment left entirely to women. Among the ancient Romans the mortar and pestle were alone used for pounding wheat, and the work was similarly done by women down to the year 173 B. C. At that date baking was established as a separate occupation, the craftsmen being called *pistores*, from *pinsere*, to pound, in allusion to their manner of preparing flour. At a subsequent date mills were introduced, of which the quern was the simplest and original form. It was called the *mola manuaria*, or *mola trusatilis*, and was worked chiefly by slaves, the labor being regarded as eminently degrading. Later the *mola asinaria* moved by animal power, and the *mola aquaria* or water mill, were employed as a substitute for hand-worked mills. Their *mola aquaria* approached in form and mechanism the rude small mills which existed in the more remote parts of Scotland and Ireland down till the early part of the present century. At the beginning of last century a pair of Roman millstones were found at Adel in Yorkshire, and described in the *Philosophical Transactions*. One stone, 20 inches in diameter, was convex in outline, while the other was concave, and retained traces of notching.

The quern, and exceedingly rude water mills, were in use throughout Great Britain for many centuries, and continued to be employed in outlying districts of Scotland and Ireland till very recent times. Strutt, in his *Chronicle of England*, says—"At what time mills were first used in Britain cannot be determined; hand-mills, which without doubt were the most ancient of any, we may conceive were known in the time of Ethelbert, king of Kent, who ruled that nation from the year 560 to the year 616; for in his laws a particular fine of twelve shillings is imposed upon any man who should corrupt the king's grinding maid;[1] hence it is also evident that they were turned and tended by women; but it is probable that before the end of the heptarchy water-mills were erected, because in ancient deeds and grants of lands we find mention made of mills, which are generally said to be situated near the water." Dr. Johnson, in his *Journey to the Western Islands of Scotland*, describes the working of the quern as seen by himself. "There are water mills," he says, "in Sky and Raasa, but where they are too far distant the housewives grind their oats with a quern or handmill, which consists of two stones about a foot and a half in diameter. The lower is a little convex, to which the concavity of the upper must be fitted. In the middle of the upper stone is a round hole, and on one side is a long handle. The grinder sheds the corn gradually into the hole with one hand, and works the handle round with the other. The corn slides down the convexity of the lower stone, and by the motion of the upper is ground in its passage." The accompanying woodcut (fig. 4) illustrates the leading forms of these primitive mills,—*a* representing a pair of rubbing stones, *b* a pot quern, and *c* an ordinary quern with hole in the centre of the upper stone into which the grain was fed, another hole towards one side for receiving the handle, and in the lower stone a spout through which the ground meal was delivered.

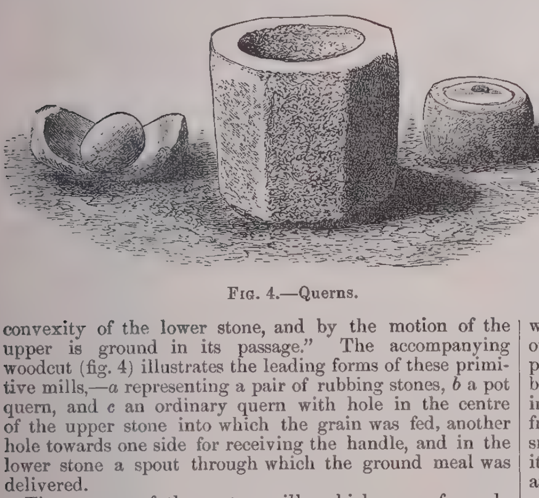

FIG. 4.—Querns.

The nature of the water mills which were formerly common in Great Britain and Ireland, and which continued in use well into the present century, may be gathered from the following description of one visited by Sir Walter Scott during his voyage to the Shetland Islands, etc., in 1814 (Lockhart's *Life*). "In our return, pass the upper end of the little lake of *Cleik-him-in*, which is divided by a rude causeway from another small loch, communicating with it, however, by a sluice, for the purpose of driving a mill. But such a mill! The wheel is horizontal, with the cogs turned diagonally to the water; the beam stands upright, and is inserted in a stone-quern of the old-fashioned construction. This simple machine is inclosed in a hovel about the size of a pig-stye, and there is the mill! There are about 500 such mills in Shetland, each incapable of grinding more than a sack at a time."

The ordinary flour mill of the present day is a structure of comparatively few essential parts; but in the arrangement and mounting of these the greatest amount of mechanical skill and experience has been exercised, and the accessories of the mill have been elaborated with much care, with the view of saving manual labor and perfecting the processes and results. Fully to appreciate the various processes of modern milling, it is necessary to bear in mind, not only that the wheat as delivered at the mill is dusty and mixed with sand and other refuse, but that it contains many light grains and seeds of foreign substances, which might be deleterious, and would certainly interfere with the appearance of the finished flour. Again, the structure of the wheat grain itself must not be overlooked. A grain (caryopsis) of wheat is not a seed, but a fruit consisting of a pericarp or outer envelope tightly adherent to its contained single seed. The envelope consists of several layers of ligneous tissue, within which are the embryo and a peculiar fermentive nitrogenous principle termed cerealin, and finally a central mass of thin cells filled with a white powdery substance largely composed of starch granules. The object of ordinary milling is to grind as perfectly as possible, without breaking the minute granules, the central substance of the grain, and to separate it from the embryo and outer husks, the former constituting the flour, and the latter the bran of the miller. Whole wheaten flour, on the other hand, consists of the entire grain ground up to a uniform mass.

The machines and processes by which flour is prepared are very numerous, and are diverse in character; and it must further be said that, at the present moment, the whole industry is in a peculiarly unsettled and transition state. The system which has prevailed in the United Kingdom hitherto is what is known as ordinary or flat grinding with millstones; but in the mean time a strong tendency is developing in favor of the use, either partially or entirely, of granulating or "high milling," and of some of the various systems of roller grinding which have been introduced. In Hungary and Austria the system of high milling prevails, in which the action of the millstones consists more in granulating than grinding; and in connection with that system of milling, the use of rollers is a prominent feature. To a limited extent also the principle of the disintegrator has been brought into operation, in which the grain is broken by the violent impact of studs or projections revolving in opposite directions with enormous velocity. Thus we have these various systems:—(1) flat milling or grinding; (2) high milling or granulation; (3) roller milling or crushing; and (4) disintegrator milling or breaking.

Flat or Ordinary Milling.—In the ordinary or flat millstone milling of the United Kingdom there are three main points to consider—(1) the cleaning and preparation of the wheat; (2) the grinding; and (3) the bolting or dressing of the ground products. The ordinary cleaning or screening apparatus through which the wheat, as received, passes, consists of a kind of cylindrical sieve of wire cloth, mounted in a sloping position, and having internal partitions so as to resemble an Archimedean screw. When the apparatus is set in motion, the grain, fed in at its upper end, tumbles from one division into another, thereby being freed from small refuse and sand, and as it issues at the lower extremity is subjected to a fan blast. For cleaning grain there are other kinds of apparatus, in which the principle of aspiration, or drawing currents of air through the grain, is now extensively employed, the most frequently used being Child's aspirator. A further cleaning is sometimes given by Child's decorticator, an implement which can be adjusted at will, for simply rubbing and scouring the grain, or for removing the thin bran and germ previous to the operation of grinding. The "Victor" brush machine is a recently introduced and highly approved apparatus for polishing and finishing wheat, its peculiar feature being that the "opposed brushes are constructed and worked in such a manner that they come in contact with every kernel of wheat in every conceivable position, and with as much force as the miller chooses to use—thus polishing it on the ends better than any other machine can do, and this not only on one pair of brushes, but on several." The prepared grain is next conveyed to the grinding apparatus, and here it may be said that, in moving the grain or flour horizontally, Archimedean screws working within an inclosed casing are employed, while in lifting from one floor to another, small boxes mounted on an endless band worked over pulleys and similarly encased are used. The grinding machinery consists first of a bin containing the grain to be ground, from which it passes by a spout to the hopper, whence it is delivered by a feeding adjustment to the stones. These constitute the distinctive feature of the entire mill.

---

[1] *Leges Ethelberti*, apud Wilkins.

and upon their condition and delicate adjustment the whole success of the milling operation turns. They consist of two flat cylindrical masses inclosed within a wooden or sheet metal case, the lower or "bed-stone" being permanently fixed, while the upper or "runner" is accurately pivoted and balanced over it. The average size of millstones is about 4 feet 2 inches in diameter by 12 inches in thickness; and they are made of a hard but cellular siliceous stone called buhr-stone, the best qualities of which are obtained from La-Ferté-sous-Jouarre, department of Seine-et-Marne, France. Millstones are generally built up of segments, bound together around the circumference by an iron hoop, and backed with plaster of Paris. The bedstone is dressed to a perfectly flat plane surface, and a series of grooves or shallow depressions are cut in it, generally in the manner shown in fig. 5, which represents the grinding surface of an upper or runner stone. The grooves on both are made to correspond exactly, so that when the one is rotated over the other the sharp edges of the grooves, meeting each other, operate like a rough pair of scissors, and thus the effect of the stones on grain submitted to their action is at once that of cutting, squeezing, and crushing. The dressing and grooving of millstones are generally done by hand-picking, but sometimes black amorphous diamonds (carbonado) are used, and emery wheel dressers have likewise been suggested. The upper stone or runner is set in motion by a spindle on which it is mounted, which passes up through the centre of the bedstone, and there are screws and other appliances for adjusting and balancing the stone. Further, provision is made within the stone case for passing through air to prevent too high a heat being developed in the grinding operation; and sweepers for conveying the flour to the meal spout are also provided. The ground meal delivered by the spout is carried forward in a conveyer or creeper box, by means of an Archimedean screw, to the elevators, by which it is lifted to an upper floor to the bolting or flour-dressing machine. The form in which this apparatus was formerly employed consisted of a cylinder mounted on an inclined plane, and covered externally with wire cloth of different degrees of fineness, the finest being at the upper part of the cylinder where the meal is admitted. Within the cylinder, which was stationary, a circular brush revolved, by which the meal was pressed against the wire cloth, and at the same time carried gradually towards the lower extremity, sifting out as it proceeded the mill products into different grades of fineness, and finally delivering the coarse bran at the extremity of the cylinder. For the operation of bolting or dressing, hexagonal or octagonal cylinders, about 3 feet in diameter and from 20 to 25 feet long, are now commonly employed. These are mounted horizontally on a spindle for revolving, and externally they are covered with silk of different degrees of fineness, whence they are called "silks" or silk dressers. Radiating arms or other devices for carrying the meal gradually forward as the apparatus revolves are fixed within the cylinders, and there is also an arrangement of beaters which gives the segments of cloth a sharp tap, and thereby facilitates the sifting action of the apparatus. Like all other mill machines, the modifications of the silk dresser are numerous. Mill products are differently assorted and classified in various localities and different mills—some distinguishing many qualities of flour and bran, and others making only three or four divisions. The following (from Professor Church's *Food*) may be taken as a fair average representation of the product of 100 lb of good white wheat:—

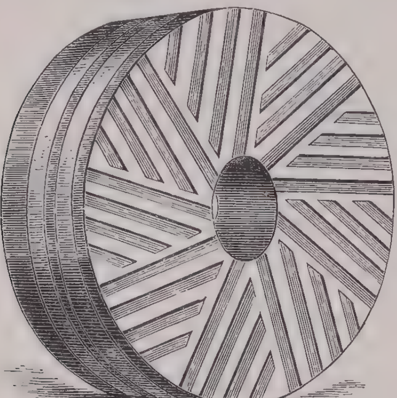

FIG. 5.—Upper Millstone, lower surface.

Flour........	1. Finest flour........................	42 lb.
	2. Seconds flour........................	18 "
	3. Biscuit flour........................	9 "
	4. Tails or tailings........................	3 "
Middlings	5. Middlings or fine sharps.........	8 "
Bran	6. Coarse sharps........................	3 "
	7. Fine pollard........................	3 "
	8. Coarse pollard........................	6 "
	9. Long bran........................	3 "
	Loss by evaporation, etc.............	5 "

In the Crown Mills, Glasgow, belonging to John Ure & Son, the classification and general average mill products, dealing with 50 qrs., are as follows:—

Flour....................................	60	to	62	bags of	280	lb.
Overheads or coarse flour............	2½	"	3	"	280	"
Fine thirds..............................	5	"	6	"	168	"

An additional proportion of fine flour is obtained by dressing and remilling tailings and middlings, and the purification and regrinding of these products have now become of much consequence in connection with the changed systems of milling rapidly coming into use. A great variety of middlings purifying machines have been introduced and eagerly pushed within the last few years, showing that this branch of economic milling is now receiving great attention.

The Hungarian System or High Milling.—The object of the low or flat milling process, as practised in Great Britain, is to produce at one grinding operation as large a proportion of good finished flour as possible. In high milling, on the other hand, the stones are kept so far apart that grain is merely bruised in the first operation, and by a series of such grindings or bruisings, alternated with elaborate sifting, the bran and all the outer envelopes with the cerealin are detached, and a nucleus of very pure semolina only left. In this way a large proportion of very inferior branny flour is obtained in these early millings, and the proportion of exceedingly fine strong flour for which Austro-Hungarian millers are famous is comparatively small. It is only to the hard brittle wheats that the Hungarian system of milling is applicable, and the method is only practicable under circumstances where there is a demand for the two extreme qualities of mill product which result from the system. Within the last few years the Hungarian millers have very largely adopted the roller mills, either to supplant entirely or to supplement the stone grinding.

Roller Mills.—In this form of mill a pair of horizontal rollers rotate face to face, and the grain or other material is submitted to their action by passing between them. The nature of that action varies according to the modification of roller surfaces, the closeness of the rollers to each other, and the equal or differential rate at which they revolve. Rollers of metal, either steel or chilled iron, having a toothed surface, revolving at different rates of speed and at definite distances apart, have a cutting action on the grain submitted to them. Such rollers are employed in the Buchholz system for reducing hulled wheat to the condition of semolina, and a similar arrangement is employed in the machine of Ganz & Co. of Buda-Pesth. Fig. 6 shows a section of the face of a pair of such rollers, where B revolving slowly serves as a holder for the grain, which is cut by the sharp edges of A, revolving at a speed three times greater than B. Smooth surface rollers are mounted to press hard against each other, and are made in some cases of polished chilled metal; and in other instances cylinders of porcelain are employed. Their principal function is for the reduction of purified middlings and semolina, and when no differential motion is given the action is simply that of squeezing, but when the opposing rollers revolve at different rates of speed a grinding effect is further superadded. A roller mill which has met great and sudden public acceptance is that invented and patented by F. Wegmann, a miller of Naples. In Wegmann's mill, fig. 7, porcelain rollers are employed, there being two pairs fed from opposite ends of one hopper in the machine figured. This machine possesses a self-acting pressure and a differential motion; but its most valuable feature consists in the employment of porcelain for rollers, by which a surface at once exceedingly hard and slightly rough or porous is secured. It is claimed for these rollers that, acting on middlings, they produce, with less expenditure of power, more and better flour than can be obtained by either stones or metal rollers. For the grinding of fine middlings English experience is, however, in favor of chilled iron rollers as the best. The roller mills have not yet been long enough in operation in Great Britain to enable any safe conclusion to be drawn as to their adaptability to British milling; but though the system originated only within the last few years, it has in the mean time practically superseded all other methods in the Austro-Hungarian districts, where milling is carried to greater perfection than in any other part of the world. To show the progress made in the introduction of roller mills in Britain, it may be noted that, while in January, 1877, there was only one Wegmann's machine in operation, there were by the close of the year 350 in various mills throughout the country.

CROSSCUP & WEST, PHILA.

Fig. 7.—Wegmann's Roller-Mill.

The Disintegrator.—Under this name a form of machine was invented and introduced a few years ago by the late Thomas Carr for, among other purposes, the manufacture of flour. Carr's disintegrator consists of a pair of circular discs of metal set face to face, and studded with circles of projecting bars so arranged that the circles of bars on the one disc alternate with those of the other. The discs are mounted on the same centre, and so closely set to each other that the projecting bars of the one disc come quite close to the plane surface of the other; and they are inclosed within an external casing into the centre of which a spout passes by which the grain is delivered into the machine. The discs are caused to rotate in opposite directions with great rapidity, making about 400 revolutions per minute, and as the outer circle of bars is 6 feet 10 inches from the centre, they move at a rate of 140 feet a second, or about 100 miles per hour. The grain in passing through the machine is struck by the oppositely revolving studs with enormous force,—a force which increases as the shattered grains approach the outer circles of studs, and it is almost instantaneously reduced to a powder which falls under the discs and is carried away by a spiral creeper. It is stated that one of these machines 7 feet in diameter is capable of doing the work of as many as 27 pairs of millstones, and they have been fully tested in the flour mills of Gibson and Walker, Bonnington, near Edinburgh, where two of them have been in operation for a period of seven years. Notwithstanding this success, however, the disintegrator has not met with general acceptance as a flour mill, having been introduced into only a very limited number of establishments. The following is a statement of the average results Messrs. Gibson and Walker have obtained by the disintegrator from old Scotch wheat and from a mixture of Baltic and Ghirka wheats respectively:—

	Old Scotch.		*Baltic and Ghirka.*	
Flour	45	per cent.	35	per cent.
Semolina	26	"	36	"
Bran flour	4½	"	4½	"
Exhaust flour	1½	"	1¼	"
Seconds	4	"	3¾	"
Parings	1¾	"	2	"
Bran	13	"	13	"
Black dust, etc.	2¾	"	3	"
Loss	1½	"	1½	"
	100		100	

The semolina is reground under stones, and yields a fine strong flour; but it may be and sometimes is reduced by passing it again through the disintegrator.

Qualities of Flour.—There appears to be at present some conflict between public demand, as indicated by the increasing attention paid to the production of a fine strong white flour, and the current of scientific opinion expressed, though with some hesitation and doubt, in favor of whole meal or flour in which the richly nitrogenous outer portions of the wheat are retained. The fact that the outer portions of the wheat are richest in nitrogenous principle, and that also in a peculiarly active form, is indisputable; but it has not been satisfactorily determined whether the nutritive value of that portion of the grain is exactly measured by its chemical composition. The condition of the nitrogenous substance, the amount and irritating nature of the ligneous tissue which accompanies it, and its peculiar influence on the other constituents of the wheat grain may and probably do affect its value. It is certain also that white flour is deliberately preferred by the laboring population, whose instinct is probably right, and it is also preferred by and for many purposes indispensable to the baker and cook. Good flour should present the appearance of a pure uniform white powder, only faintly tinged with yellow, free from all grit and lumps; and when pressed in the hands it ought to show a certain amount of adhesiveness. It should be free from all smell of damp or mouldiness, and it should have no acidity of taste. For the purposes of the baker its strength is measured by the amount and quality of its gluten or nitrogenous constituents, which may be roughly estimated by making up a little dough and observing its tenacity when drawn out; but a more accurate means of measuring its elasticity is provided by the aleurometer of M. Boland, a Parisian baker. The following analytical statement of the constituents of flour, and other calculations concerned therewith, are extracted from Professor Church's *Handbook of Food*, prepared for the Science and Art Department:—

Composition of Fine Flour from White Soft Wheat.

	In 100 parts.	In 1 lb.			
Water.	13·0	2	oz.	35	grs.
Fibrin, etc.	10·5	1	"	297	"
Starch, etc.	74·3	11	"	388	"
Fat	0·8	0	"	57	"
Cellulose	0·7	0	"	44	"
Mineral matter	0·7	0	"	49	"

"One pound of good wheaten flour, when digested and oxidized in the body, might liberate force equal to 2283 tons raised one foot high. The greatest amount of external work which it could enable a man to perform is 477 tons raised one foot high. For one part of flesh-formers in fine wheaten flour there are 7¼ parts of heat-givers reckoned as starch. One pound of wheaten flour cannot produce more than about 1⅔ oz. of the dry nitrogenous substance of muscle or flesh."

Statistics of the Flour Trade.—The disproportion between the grain producing and consuming capacity of the United Kingdom is very great and yearly increasing, and the deficiency in our own crops is made good from almost all quarters of the globe. In the discussion of this principal portion of the British food supply, the whole grain crops of the kingdom and the entire imports of all kinds of grain would require to be taken into consideration, and this large question cannot be here entered upon. The extent of our import trade in wheat and flour is indicated by the following table, relating to the five years 1872–6; and the detailed statement for 1876 gives the principal sources whence these supplies are drawn:—

Total Imports of Wheat and Flour, 1872–1876.

Year.	Wheat.		Wheat Meal and Flour.	
	Cwt.	Value.	Cwt.	Value.
1872	42,127,726	£26,169,185	4,388,136	£4,087,639
1873	43,863,098	28,538,746	6,214,479	5,849,852

(J. PA.)

FLOURENS, GUSTAVE (1838–1871), a French social democrat and writer, a son of M. J. P. Flourens, was born at Paris, August 4, 1838. Before he had attained his twenty-first year he obtained at the college of Louis-le Grand the diplomas of licentiate in letters and in sciences. In 1863 he undertook for his father a course of lectures at the Collége de France, the subject of which was the history of mankind. His theories as to the manifold origin of the human race, however, gave offence to the clergy, and he was precluded from delivering a second course. He then repaired to Brussels, where he published his lectures under the title of *Histoire de l'Homme;* he next visited Constantinople and Athens, took part in the Cretan insurrection of 1866, spent some time in Italy, where an article of his in the *Popolo d'Italia* caused his arrest and imprisonment, and finally, having returned to France, nearly lost his life in a duel with Paul de Cassagnac, editor of the *Pays*. In Paris he devoted his pen to the cause of republicanism, and at length, having failed in an attempt to organize a revolution at Belleville, February 7, 1870, found himself compelled to flee from France. Returning to Paris on the downfall of Napoleon, he soon placed himself at the head of a body of 500 tirailleurs. On account of his insurrectionary proceedings he was taken prisoner at Créteil, near Vincennes, by the provisional government, and confined at Mazas, December 7, 1870, but was released by his men on the night of January 21–22. On the 18th March he joined the Communists. As colonel of the 19th and 20th arrondissements he took part in an attack on Versailles, and early in the morning of the 3d of April was killed in a hand-to-hand conflict at Rueil, near Malmaison. Besides his *Science de l'Homme* (Paris, 1869), Gustave Flourens was the author of numerous fugitive pamphlets.

FLOURENS, MARIE JEAN PIERRE (1794–1867), a celebrated French physiologist, was born at Maureilhan, near Béziers, in the department of Hérault, April 15, 1794. At the age of fifteen he began the study of medicine at Montpellier, where in 1823 he received the degree of doctor. In the following year he repaired to Paris, provided with an introduction from De Candolle, the botanist, to Cuvier, who received him kindly, and interested himself in his welfare. At Paris Flourens engaged in physiological research, occasionally contributing to literary publications; and in 1821, at the Athénée there, he gave a course of lectures on the physiological theory of the sensations, which attracted much attention amongst men of science. His paper entitled *Recherches expérimentales sur les propriétés et les fonctions du système nerveux dans les animaux vertébrés*, in which he, from experimental evidence, sought to assign their special functions to the cerebrum, corpora quadrigemina, and cerebellum, was the subject of a highly commendatory report by Cuvier, adopted by the French Academy of Sciences, July 22, 1822. He was chosen by Cuvier in 1828 to deliver for him a course of lectures on natural history at the Collége de France, and in the same year became, in succession to Bosc, a member of the Institute, in the division "Économie rurale." In 1830 he became Cuvier's substitute as lecturer on human anatomy at the Jardin du Roi, and in 1832 was elected to the post of titular professor, which he vacated for the professorship of comparative anatomy created for him at the museum of the Jardin the same year. In 1833 Flourens, in accordance with the dying request of Cuvier, was appointed a perpetual secretary of the Academy of Sciences; and in 1838 he was returned as a deputy for the arrondissement of Béziers. In 1840 he was elected, in preference to Victor Hugo, to succeed Michaud at the French Academy; and he was created on April 24, 1845, a commander of the legion of honor, and in the next year a peer of France. In March, 1847, Flourens directed the attention of the Academy of Sciences to the anæsthetic effect of chloroform on animals; and it is an interesting fact in the history of therapeutics that "chloric ether," a spirituous solution of chloroform, was in the spring of the same year first employed, at the suggestion of Dr. M. C. Furnell, in surgical operations at St. Bartholomew's Hospital. On the revolution of 1848, Flourens withdrew completely from the political world; and in 1855 he accepted the professorship of natural history at the Collége de France. Three years before his death, which took place at Montgeron near Paris, December 6, 1867, he retired from his active duties at the Academy of Sciences.

As an experimental physiologist Flourens holds the highest rank. Besides a multitude of shorter scientific memoirs, he published—*Essai sur quelques points de la doctrine de la révulsion et de la dérivation*, Montpellier, 1813; *Expériences sur le système nerveux*, Paris, 1825; *Cours sur la génération, l'ovologie, et l'embryologie*, 1836; *Analyse raisonée des travaux de G. Cuvier*, 1841; *Recherches sur le développement des os et des dents*, 1842; *Anatomie générale de la peau et des membranes muqueuses*, 1843; *Buffon, histoire de ses travaux et de ses idées*, 1844; *Fontenelle, ou de la philosophie moderne relativement aux sciences physiques*, 1847; *Théorie expérimentale de la formation des os*, 1847; *Œuvres complètes de Buffon*, 1853; *De la longévité humaine et de la quantité de vie sur le globe*, 1854, numerous eds.; *Histoire de la découverte de la circulation du sang*, 1854; *Cours de physiologie comparée*, 1856; *Recueil des éloges historiques*, 1856; *De la vie et de l'intelligence*, 1858; *De la raison, du génie, et de la folie*, 1861; *Ontologie naturelle*, 1861; *Examen du livre de M. Darwin sur l'Origine des Espèces*, 1864. For list of papers see Royal Society's *Catalogue*, vols. ii. and vii.

FLOWERS, Artificial. There are few branches of ornamental work used in the decoration of ladies' apparel which have more increased in importance than that of artificial flower making, in which, both in France and in England, large numbers of workpeople are engaged. Not only has the trade itself greatly extended within the last few years, but the improvement in the manufacture is very marked, and the bouquets and wreaths used in the trimming of dresses may be almost said to rival nature, so truly and delicately are the individual flowers manipulated. Artificial flower making is almost entirely done by hand, giving occupation principally to young women and children, the majority of whom work at home or in small shops. The numbers employed at the time of the census of 1871 were returned as 4886, of whom 1740 were under twenty years of age. In France the numbers are much larger, for ten years ago it was estimated that there were at least 2000 shops where artificial flowers were made, and it is probable that now these have been increased to 3000. It is not entirely a woman's work, however, for men are employed, particularly in Paris, in cutting out the material for the flowers by a stamp machine, in which 16 or 20 folds are operated upon at once, the folds being colored green, blue, crimson, according to the flower which is to be imitated. Each piece is taken up separately by a girl armed with a pair of pincers, who, with one dexterous movement, moulds it, as it were, roughly into the shape of the flower, and then passes it on to another, who gives a more precise form to the petal. A third girl attaches each petal to a very fine wire, thread having been previously twisted round this wire to form the stalk; while the remaining operations consist in goffering the petals and leaves to give them a curl, and finally gumming or waxing them over, or dusting them with fine powdered glass or potato flour to represent the bloom. The rapidity and accuracy with which these various processes are completed are very remarkable. A new style of artificial flower has lately come into vogue, in France more especially, made by the "enamel process," in which a young girl sits by a jet of flame, holding in her hand a stick of prepared glass. A momentary application to the flame makes the end of the stick red hot, and while it is still in a pasty state, the operator pulls out a short length, and immediately rolls it up into the form of the petal or leaf, and passes it on to the painter for the proper coloring. The remaining processes are similar to those of the ordinary artificial flowers. These enamel flowers, though wondrously true and pretty, are more suited for room decoration than for dress. While apparently a light and pleasant work, artificial flower making is not one of the healthiest of our trades, partly for the reason that it is so often carried on in small household shops, where ventilation is of the scantiest. It has, however, been much improved in this respect since it has come under the supervision of the Factory Acts. There is always a certain amount of dust and coloring matter flying about the room, which is more or less injurious, though the use of Scheele's green and sulphate of copper (verdigris blue) is almost discontinued, and with it a train of symptoms that usually accompany arsenical poisoning. Weak eyes are a common source of complaint, especially the form called asthenopia, which is particularly induced when white flowers are made by gas light. In the manufacture of the flowers, the net cost is about three-fifths of the whole for material, and the remaining two-fifths for the labor. In France the earnings of the men who cut the folds are from 4 to 5 francs per day, of the workwomen from 2½ to 3½, according to ability. In England a skilful flower worker will earn from 20s. to 25s. per week, though there is a drawback in its being a season trade, which is very brisk about the spring and fall of the year, and as inactive during the other times. Besides the very large number of artificial flowers made in England, the following table shows how great is the importation, principally from France:—

1866	£293,306	1870	£266,502	1874	£447,351
1867	304,440	1871	367,186	1875	510,800
1868	341,176	1872	411,540	1876	496,987
1869	365,407	1873	449,320	1878	544,625

Belgium and Holland likewise supply Great Britain but to a much smaller extent.

FLOYER, Sir John (1649–1734), M.D., physician and author, was born at Hinters in Staffordshire, and was educated at Oxford. He practised in Lichfield, and it was by his advice that Dr. Johnson, when a child, was taken by his mother to be touched by Queen Anne for the king's evil, March 30, 1714. Dr. Johnson had a high opinion of his learning and piety. Floyer died February 1, 1734. Besides letters and other short pieces in various publications, he wrote—

Φαρμακο-Βάσανος: *or the Touch-stone of Medicines, discovering the virtues of Vegetables, Minerals, and Animals, by their tastes and Smells*, 2 vols., 1687; *The præternatural State of animal Humors described by their sensible Qualities*, 1696; *An Enquiry into the right Use and Abuses of the hot, cold, and temperate Baths in England*, 1697; *A Treatise of the Asthma*, 1st ed., 1698; *The ancient Ψυχρο-λουσία revived, or an Essay to prove cold Bathing both safe and useful*, London, 1702 (several editions 8vo; abridged, Manchester, 1844, 12mo); *The Physician's Pulse-watch*, 1707–10; *The Sibylline Oracles, translated from the best Greek copies, and compared with the sacred Prophecies*, 1st ed., 1713; *Two Essays: the first Essay concerning the Creation, Ætherial Bodies, and Offices of good and bad Angels; the second Essay concerning the Mosaic System of the World*, Nottingham, 1717; *An Exposition of the Revelations*, 1719; *An Essay to restore the Dipping of Infants in their Baptism*, 1722; *Medicina Gerocomica, or the Galenic Art of preserving old Men's Healths*, 1st ed., 1724; *A Comment on forty-two Histories described by Hippocrates*, 1726.

FLUDD, Robert (Latin *Robertus De Fluctibus*), (1574–1637), an English physician and mystical philosopher, was the son of Sir Thomas Fludd, treasurer of war to Queen Elizabeth in France and the Low Countries, and was born at Milgate, Kent, in 1574. After studying at Oxford he spent six years in travelling in Europe. While on the Continent he became acquainted with the writings of Paracelsus, and he was so fascinated with them that he endeavored to form a system of philosophy founded on the identity of physical and spiritual truth. He believed in two universal principles, the northern or condensing and the southern or rarefying power, and in the existence of four elemental spirits corresponding to fire, air, earth, and water. The central principle of his philosophy was that man was a representation or miniature of the universe, and he endeavored to trace the analogy between what he called the microcosm and the macrocosm. The opinions of Fludd, preposterous as they now seem, had the honor of being refuted by Kepler, Gassendi, and Mersenne. Though rapt in mystical speculation, Fludd did not disdain scientific experiments, and is thought by some to be the original inventor of the barometer. He died in 1637. De Quincey considers Fludd to have been the immediate father of freemasonry, as Andrea was its remote father.

Fludd wrote two books against Mersenne, the first entitled *Sophiæ cum Moria Certamen*, etc., 1629; and the second, *Summum Bonorum quod est verum Magiæ, Cabalæ*, etc., 1629. Among his other works were—*Utriusque Cosmi, majoris et minoris, Technica Historia*, 1617; *Tractatus Apologeticus integritatem Soc. de Rosea Cruce defendens*, 1617; *Monochordon Mundi symphoniacum, seu Replicatio ad Apologiam Joannis Kepleri*, 1620; *Anatomiæ Theatrum triplici effigie designatum*, 1623; *Philo-*

sophia Sacra, 1626; *Medicina Catholica*, 1626; *Integrum Morborum Mysterium*, 1631; *De Morborum Signis*, 1631; *Clavis Philosophiæ et Alchymiæ Fluddianæ*, 1633; *Philosophia Mosaica*, 1638; and *Pathologia Dæmoniaca*, 1640. See De Quincey's Works, vol. xvi. pp. 406–412.

FLÜGEL, Gustav Lebrecht (1802–1870), a German Orientalist, was born at Bautzen, February 18, 1802. He received his early education at the gymnasium of his native town, and studied theology and philology at Leipsic. Gradually he devoted his attention chiefly to Oriental languages, which he studied especially at the universities of Vienna and Paris. In 1832 he became professor at the district school of Meissen, but ill health compelled him to resign that office in 1850, and in 1851 he went to Vienna, where he was employed in cataloguing the Oriental manuscripts of the court library. He died at Dresden, July 5, 1870.

His chief works are an edition of the *Koran*, originally published at Leipsic in 1834, followed by *Concordantiæ Corani Arabicæ*, Leipsic, 1842; *Geschichte der Araber*, Leipsic, 1832–1840; *Dictionary of Hadschi-Chalfa*, with Latin translation and commentary, in 7 vols., London and Leipsic, 1835–1858 (published at the expense of the London Oriental Translation Committee); *Mani, seine Lehren und seine Schriften*, Leipsic, 1862; *Die grammatischen Schulen der Araber*, Leipsic, 1862.—An edition of *Kitâb-al-Fihrist*, prepared by Flügel, was published posthumously at Leipsic in 1871, and he also edited various other Oriental works.

FLÜGEL, Johann Gottfried (1788–1855), a German lexicographer, was born at Barby near Magdeburg, 22d November, 1788. He was originally a merchant's clerk, but emigrating to America in 1810, he made a special study of the English language, and returning to Germany in 1819, he was in 1824 appointed professor of the English language in the university of Leipsic. In 1838 he became American consul, and subsequently representative and correspondent of many literary and scientific institutions of America. He died 24th June, 1855.

The fame of Flügel rests chiefly on his *Vollständige englisch-deutsche und deutsch-englische Wörterbuch*, first published in 2 vols. at Leipsic in 1830, which has had an extensive circulation not only in Germany but in England and America. Among his other works are—*Vollständige engl. Sprachlehre*; *Triglotte, oder Kaufmännisches Wörterbuch in drei Sprachen, deutsch, englisch, und französisch*; *Kleines Kaufmännisches Handwörterbuch in drei Sprachen*; and *Praktisches Handbuch der engl. Handelscorrespondenz*. All these have passed through several editions.

FLUORINE, one of the halogen group of chemical elements, symbol F, atomic weight 19·1. The compound fluorine forms with hydrogen, namely, hydrofluoric acid, or hydrogen fluoride, was known so long ago as 1670 for its property of etching glass; by Scheele it was regarded as a substance containing oxygen with some other element; and by Ampère, in 1810, it was shown to consist of hydrogen with a new element, which from its source fluor spar received the name of fluorine. Fluorine is one of the less abundant, but one of the most widely diffused of the elements. It occurs in nature always combined with other elements, as in fluor spar (see below), in Cryolite (*q.v*, vol. vi. p. 590), and in fluor-apatite; in the rarer minerals topaz, yttrocerite, wagnerite, wavellite, and others; also in small quantities in some granites and trap rocks; in river and mineral waters; and in sea water, according to Forchhammer, to the extent of half a grain in 100 ℔. Bischoff draws attention to the fact that no trace of fluorine is to be found in augite. It is a constant constituent of teeth and bones—in fossil in larger quantity than in recent bones; and it has been detected in corals, and in the ashes of milk and of ox-blood. Attempts to isolate fluorine have been made by several experimenters, but its strongly negative properties, by occasioning its combination with the material of most vessels employed to receive it, have hitherto proved an obstacle to its investigation in the free state. The presence of fluorine in minerals is usually detected by their evolution of hydrofluoric acid when heated with sulphuric acid, and the action of the evolved acid on glass. For the quantitative estimation of fluorine, its compounds may be decomposed by means of sulphuric acid or acid sulphate of ammonium, the fluorine being determined either by loss, or directly in the form of silicofluoride of potassium, sodium, or barium, according to Wöhler's method. To obtain their fluorine in a soluble combination many minerals require fusion with alkaline carbonates. Free hydrofluoric acid and soluble fluorides are best determined by means of calcium chloride, which affords a precipitate of calcium fluoride, or fluor spar. See further, on the compounds of fluorine and their reactions, Chemistry, vol. v. pp. 424–428.

FLUOR SPAR, Fluorite, or Calcium Fluoride, CaF_2 (Germ. *Fluss-spath*), the "blue John" of Derbyshire, and "cann" or "kann" of Cornish miners, occurs crystallized in simple or modified cubes and octahedrons; also nodular, compact and granular, and more rarely fibrous, or soft and earthy. Some octahedral crystals from the mines of St. Agnes, in Cornwall, are made up of minute cubes, which may themselves show faces of other forms of the monometric system of crystallography. Fluor spar is a brittle, transparent to sub-translucent mineral, with a perfect octahedral cleavage, a vitreous, sometimes splendent lustre, a hardness of 4, and a specific gravity of 3·01–3·25. Before the blowpipe it decrepitates, tinges the flame dull red, and fuses into an enamel. Heated with concentrated sulphuric acid it yields hydrofluoric acid (see Chemistry, vol. v. p. 425). In color fluor spar varies much, being blue, purple, green, yellow, pink, or brown; it is sometimes dichroic. The colors are attributed by Wyrouboff to the presence of minute quantities of hydrocarbons, taken up from solutions from which the mineral has crystallized; by others they are considered to be due to peculiarities of molecular structure. In the Weardale fluors small cavities containing liquid have occasionally been found. Fluor spar, in common with some other substances, when exposed to light, or when raised to a temperature somewhat under redness, usually phosphoresces, emitting a bright light, the color of which is not dependent on that of the mineral. A variety of fluor spar has received its name chlorophane from its fine green phosphorescence. Like the color, the phosphorescence of fluor-spar is destroyed by exposure to a high temperature; it may be partly restored by means of an electric discharge, or, it is said, by moistening with dilute hydrofluoric acid. From the name of the mineral Professor Stokes borrowed the term "fluorescence," applied by him to the quality which certain bodies, *e.g.*, sulphate of quinine, possess of rendering the ultra-violet rays of the spectrum visible. W. Hankel (*Ann. Phys. Chem.* [2], ii. 66–83), experimenting on crystals of fluor spar from Weardale, found that when exposed to light they exhibited not only phosphorescence but electrical phenomena; the rays of the sun, however, concentrated by a lens, deprived the crystals of their photo-electrical property, which they did not regain. Fluor spar is slightly soluble in water containing hydrated calcium carbonate. Pseudomorphs of hornstone, hematite, calamine, and other minerals after fluor spar are not unfrequent. Fluor spar is commonly used for the production of hydrofluoric acid in etching on seals and glass, and in the smelting of lead and copper and in other metallurgical operations as a flux, whence its name, from the Latin *fluo*, to flow. The manufacture of vases and other ornamental articles from fluor spar, especially the variegated varieties, has long been carried on in Derbyshire. The stone, which is sometimes first heated to change its blue to an amethystine tint, is shaped by means of the lathe and a fine steel tool, and is finished off with coarse stone, and after that with pumice and emery. Fluor spar is of frequent occurrence in metalliferous veins, being most commonly associated with ores of lead, as in the mines of Derbyshire, Cumberland, Cornwall, Saxony, and Bohemia. It is met with also in granite, gneiss, slates, various limestones and sandstones, and some volcanic products, and has occasionally been detected in beds of coal.

On the phosphorescence of fluor spar see Prof. C. Bohn's paper on "Negative Fluorescence and Phosphorescence," *Phil. Mag.* [4], vol. xxxiv. p. 109, 1867.

FLUSHING (Dutch *Vlissingen*), a fortified seaport town of the province of Zealand, Holland, is situated on the island of Walcheren, at the mouth of the estuary of the Western Scheldt, about 4 miles S. of Middleburg, and 50 miles S.W. of Rotterdam. It possesses an academy of sciences, a school of navigation, a town-hall, a theatre, an exchange, and a statue to Admiral Ruyter, who was born here in 1607. Since 1872 it has had direct railway connection with the main lines of Europe; and by the construction in 1873 of a great harbor, docks, and canal works a communication between it and the North Sea has been opened up for vessels of the largest size. The outer harbor has a surface of 33·11 acres, and a depth at low water of 22 feet; the depth of both the inner harbors at low water is 27 feet, the surface of the one being 16·55 acres and that of the other 11·86 acres. With these works Flushing possesses one of the finest and safest harbors of the Continent, and the one on the Dutch coast best adapted for the trade of Holland and Germany. Its chief exports are wheat, beans, fish (especially shrimps), and cattle; and its chief imports coal from England, and coffee, tea, and tin from Java. The number of vessels entering and clearing annually is upwards of 100. Besides the shipping trade the chief industries are brewing and the manufacture of oil and soap. Flushing was one of the "cautionary towns" delivered up to Queen Elizabeth in 1585 in security for the money and soldiers sent by her to assist the Dutch under Sir Philip Sidney. It was captured by the French in 1795, and in 1809 it was bombarded by the English under Lord Chatham, and did not surrender till the fine town-hall, two churches, and about 100 houses were destroyed. Its fortifications have since that time been greatly strengthened, and now completely command the entrance to the river. Population in 1869, 8929.

FLUSHING, a post-village of Queens county, New York, is situated on Long Island at the head of Flushing Bay, about 7 miles N.E. of New York, and 8 N.E. of Brooklyn. It possesses a State bank, a savings bank, an academy, a female seminary, and several other educational institutions. It is the residence of many of the New York merchants, and is noted for its large gardens and nurseries. Population in 1870, 6223.

FLUTE, a wind instrument which in a variety of forms has been in constant use from the earliest ages. To Olympus the Phrygian has been ascribed the introduction of flute-playing into Greece, an art which was much encouraged in the later days of the empire. The Greeks employed professional flute-players in many of their religious ceremonies, and competitive trials of skill were frequent. The old English flute, called the *flute-à-bec*, from the supposed resemblance of the mouthpiece to the beak of a bird, was played from the upper and wider end, had seven finger holes, and was made of various sizes, called treble, alto, tenor, and bass flutes respectively. This instrument continued in common use to about the middle of the 18th century, when it was gradually superseded by the modern horizontal (*flauto traverso*) or "German" flute. Handel was one of the first to introduce the new instrument into the orchestra, employing it for solos in *The Ode on Saint Cecilia's Day* (1739), notably in the air "The soft complaining Flute." But the capacities of the *traverso* of Handel's time were very limited in comparison with those of its modern representative, which possesses a workable compass of about three octaves from the low C in the treble clef, with all the chromatic intervals. Various systems of fingering have been introduced from time to time by the most eminent flautists and flute-makers, and concertos for the flute as a solo instrument have been composed with a view to exhibiting the powers of celebrated performers. In orchestral scores the flute part is generally placed at the top, and is written in the violin or G clef. The *piccolo* or octave flute, the E flat or *tierce*, the D flat or *minor ninth* (transposing piccolo), the *flute d'amour*, a minor third below the ordinary instrument—are all varieties of the *traverso*, which like the fife is blown by an oval shaped hole in the side, near the stopped end of the tube. Other branches, now obsolete, of the flute family were—the *recorder*, varying in length of tube from about twelve inches to three feet, the largest being known as the *bass recorder;* the *cornet*, shaped like a quadrant, and gradually tapering towards the mouthpiece; and the *pilgrim's staff*, having a tube about six feet in length. For other less important varieties the reader is referred to *Musurgia*, Luscinius, 1536; *Harmonie Universelle*, Mersenne, 1636. Among the foundation stops of most organs will generally be found one or more "flute" stops *e.g.*, the *hohl flöte*, of eight feet tone, and the octavo flute, of four feet tone. The flageolet is a smaller variety of the old *flute-à-bec*, and was formerly used in the orchestra. Handel has written an *obbligato* part for it in the well-known barytone air "O, ruddier than the cherry." The fife, much used in military bands, is simply an octave flute in D, played horizontally, and having six finger holes and one key.

FLY. See DIPTERA and INSECTS.

FLYCATCHER, a name introduced in ornithology by Ray, being a translation of the *Muscicapa* of older authors, and applied by Pennant to an extremely common English bird, the *M. grisola* of Linnæus. It has since been used in a general and very vague way for a great many small birds from all parts of the world which have the habit of catching flies on the wing, and thus ornithologists who have trusted too much to this characteristic and to certain merely superficial correlations of structure, especially those exhibited by a broad and rather flat bill and a gape beset by strong hairs or bristles, have associated under the title of *Muscicapidæ* an exceedingly heterogeneous assemblage of forms that, though much reduced in number by later systematists, has scarcely yet been sufficiently revised. Great advance has been made, however, in establishing as independent Families the *Todidæ* and *Eurylæmidæ*, as well as in excluding from it various members of the *Ampelidæ*, *Cotingidæ*, *Tyrannidæ*, *Vireonidæ*, *Mniotiltidæ*, and perhaps others, which had been placed within its limits. These steps have left the *Muscicapidæ* a purely Old-World family of the Order *Passeres*, and the chief difficulty now seems to lie in separating it from the *Campephagidæ* and the *Laniidæ*. Every ornithologist must own that its precise definition is at present almost impossible, and must await that truer knowledge which comes of investigating structural characters more deeply seated than any afforded by the epidermis. But here want of space forbids the pursuit of this kind of inquiry, and for the same reason only a very few of the forms of Flycatchers (which, after all the deductions above mentioned, may be reckoned to include some 60 genera or subgenera, and perhaps 250 species) can be even named.[1]

The best known bird of this Family is that which also happens to be the type of the Linnæan genus *Muscicapa*—the Spotted or Gray Flycatcher (*M. grisola*) already mentioned. It is a common summer visitant to nearly the whole of Europe, and is found throughout Great Britain, though less abundant in Scotland than in England, as well as in many parts of Ireland, where, however, it seems to be but locally and sparingly distributed. It is one of the latest of our migrants to arrive, and seldom reaches these islands till the latter part of May, when it may be seen, a small dust-colored bird, sitting on the posts or railings of our gardens and fields, ever and anon springing into the air, seizing with an audible snap of its bill some passing insect as it flies, and returning to the spot it has quitted, or taking up some similar station to keep watch as before. It has no song, but merely a plaintive or peevish call-note, uttered from time to time with a jerking gesture of the wings and tail. It makes a neat nest, built among the small twigs which sprout from the bole of a large tree, fixed in the branches of some plant trained against a wall, or placed in any hole of the wall itself that may be left by the falling of a brick or stone. The eggs are from four to six in number, of a pale greenish-blue, closely blotched or freckled with rust-color. Silent and inconspicuous as is this bird, its constant pursuit of flies in the closest vicinity of our houses makes it a familiar object to almost everybody. A second British species is the Pied Flycatcher (*M. atricapilla*)—called by some writers the Coldfinch—a much rarer bird, and in England not often seen except in the hilly country extending from the Peak of Derbyshire to Cumberland, and more numerous in the lake district than elsewhere. It is not common in Scotland, and has only once been observed in Ireland. More of a woodland bird than the former, the brightly-contrasted black and white plumage of the cock, together with his agreeable song, readily attracts attention where it occurs. It is a summer visitant to all Western Europe, but further eastward its place is taken by a nearly allied species (*M. collaris*) in which the white of the throat and breast extends like a collar round the neck. A fourth European species (*M. parva*), distinguished by its very small size and red breast, has also strayed some three or four times to the extreme south-west of England. This last belongs to a group of more eastern range, which has received generic recognition (possibly well deserved) under the name of *Erythrosterna*, and it has several relations in Asia and particularly in India, while the allies of the Pied Flycatchers (*Ficēdula* of Brisson) are chiefly of African origin, and those of the Gray or Spotted Flycatcher (*Muscicapa* proper[1]) are common to the two continents.

---

[1] Of the 30 genera or subgenera which Swainson included in his *Natural Arrangement and Relations of the Family of Flycatchers* (published in 1838), at least 19 do not belong to the *Muscicapidæ* at all, and one of them. *Todus*, not even to the Order *Passeres*. It is perhaps impossible to name any ornithological work whose substance so fully belies its title as does this treatise. Swainson wrote it filled with faith in the so-called "Quinary System"—that fanciful theory, invented by Macleay, which misled and hindered so many of the best English zoologists of his generation from the truth,—and, unconsciously swayed by his bias, his judgment was warped to fit his hypothesis.

One of the most remarkable groups of *Muscicapidæ* is that known as the Paradise Flycatchers, forming the genus *Tchitrea* of Lesson. In nearly all the species the males are distinguished by the growth of exceedingly long feathers in their tail, and by their putting on, for some part of the year at least, a plumage generally white, but almost always quite different from that worn by the females, which is of a more or less deep chestnut or bay color, though in both sexes the crown is of a glossy steel-blue. They are found pretty well throughout Africa and tropical Asia to Japan, and seem to affect the deep shade of forests rather than the open country. The best-known species is perhaps the Indian *T. paradisi;* but the Chinese *T. incii*, and the Japanese *T. princeps*, from being very commonly represented by the artists of those nations on screens, fans, and the like, are hardly less so; and the cock of the last named, with his bill of a pale greenish-blue and eyes surrounded by bare skin of the same color—though these are characters possessed in some degree by all the species—seems to be the most beautiful of the genus. *T. bourbonnensis*, which is peculiar to the islands of Mauritius and Réunion, appears to be the only species in which the outward difference of the sexes is but slight. In *T. corvina* of the Seychelles, the adult male is wholly black, and his middle tail-feathers are not only very long but very broad. In *T. mutata* of Madagascar, some of the males are found in a blackish plumage, though with the elongated median rectrices white, while in others white predominates over the whole body; but whether this sex is here actually dimorphic, or whether the one dress is a passing phase of the other, is at present undetermined. Some of the African species, of which many have been described, seem always to retain the rufous plumage, but the long-tail feathers serve to mark the males; and the whole group deserves far more investigation than it has ever received, as it is likely to reveal facts of the highest importance in regard to the theory of "Sexual Selection."

On the other groups of the Family there is not room to descant. A few are distinguished by the brilliant blue they exhibit, as *Myiagra azurea*, and others as *Monarcha* (or *Arses*) *chrysomela* by their golden-yellow. The Australian forms assigned to the *Muscicapidæ* are very varied, and probably require much further scrutiny. *Sisura inquieta*, for instance, has some of the habits of a Water-Wagtail (*Motacilla*), and hence has received from the colonists the name of "Dishwasher," bestowed in many parts of England on its analogue; and the many species of *Rhipidura* or Fantailed Flycatchers, which occur in various parts of the Australian Region, have manners still more singular—turning over in the air, it is said, like a Tumbler Pigeon, as they catch their prey; but concerning the mode of life of the majority of the *Muscicapidæ*, and especially of the numerous African forms, hardly anything is known. (A. N.)

FLYING AND FLYING MACHINES. See FLIGHT.

FLYING-FISH are of two different kinds. The one (*Dactylopterus*) belongs to the Gurnard family (*Triglidæ*), and is more properly called Flying Gurnard; the other (*Exocœtus*) has been called Flying Herring, though more nearly allied to the Gar-pike than to the Herring. Some other fishes with long pectoral fins (*Pterois*) have been stated to be able to fly, but this has been proved to be incorrect. The Flying Gurnards are much less numerous than the *Exocœti* with regard to individuals as well as species, there being only three or four species known of the former, whilst more than fifty have been described of the latter, which, besides, are found in numerous shoals of thousands. The *Dactylopteri* may be readily distinguished by a large bony head armed with spines, hard keeled scales, two dorsal fins, etc. The *Exocœti* have thin, deciduous scales, only one dorsal fin, and the ventrals placed far backwards, below the middle of the body; some have long barbels at the chin. In both kinds the pectoral fins are greatly prolonged and enlarged, modified into an organ of flight, and in many species of *Exocœtus* the ventral fins are similarly enlarged, and evidently assist in the aërial evolutions of these fishes. Flying fishes are found in the tropical and sub-tropical seas only, and it is a singular fact that the geographical distribution of the two kinds is nearly identical. The literature on the subject of flying fishes is very extensive, and great diversity of opinion exists among observers as regards the mode and power of their flight; but the most reliable agree that the fishes do not leave the water for the purpose of catching insects, and that they are unable to move their fins in the manner of a bat or bird, or to change voluntarily the direction of their flight, or to fly beyond a very limited distance. The most recent inquiries are those of K. Möbius (*Die Bewegungen der Fliegenden Fische durch die Luft*, Leip. 1878, 8vo), the chief results of which may be summed up thus. Flying fish are more frequently observed in rough weather and in a disturbed sea than during calms; they dart out of the water when pursued by their enemies or frightened by an approaching vessel, but frequently also without any apparent cause, as is also observed in many other fishes; and they rise without regard to the direction of the wind or waves. The fins are kept quietly distended, without any motion, except an occasional vibration caused by the air whenever the surface of the wing is parallel with the current of the wind. Their flight is rapid, but gradually decreasing in velocity, greatly exceeding that of a ship going 10 miles an hour and a distance of 500 feet. Generally it is longer when the fishes fly against, than with or at an angle to, the wind. Any vertical or horizontal deviation from a straight line is not caused at the will of the fish, but by currents of the air; thus they retain a horizontally straight course when flying with or against the wind, but are carried towards the right or left whenever the direction of the wind is at an angle with that of their flight. However, it sometimes happens that the fish during its flight immerses its caudal fin in the water, and by a stroke of its tail turns towards the right or left. In a calm the line of their flight is always also vertically straight or rather parabolic, like the course of a projectile, but it may become undulated in a rough sea, when they are flying against the course of the waves; they then frequently overtop each wave, being carried over it by the pressure of the disturbed air. Flying fish often fall on board of vessels, but this never happens during a calm or from the lee side, but

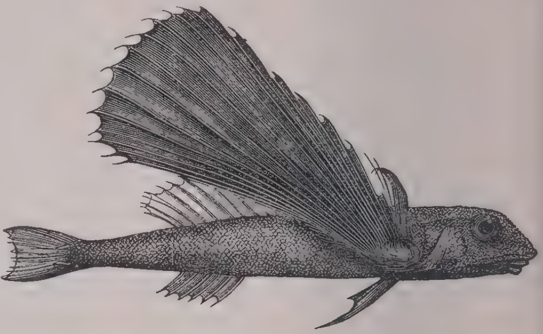

FIG. 1.—*Dactylopterus volitans.*

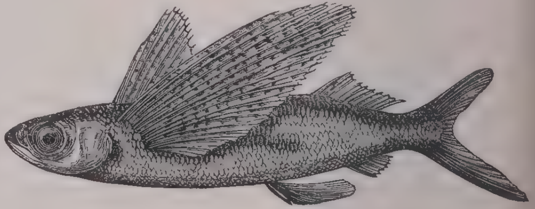

FIG. 2.—*Exocœtus callopterus.*

---

[1] By some writers this section is distinguished as *Butalis* of Boie, but to do so seems contrary to rule.

during a breeze only and from the weather side. In day time they avoid a ship, flying away from it, but during the night, when they are unable to see, they frequently fly against the weather board, where they are caught by the current of the air, and carried upwards to a height of 20 feet above the surface of the water, whilst under ordinary circumstances they keep close to it. All these observations point clearly to the fact that any deflexion from a straight course is due to external circumstances, and not to voluntary action on the part of the fish.

FLYING FOX, or more correctly Fox Bat, a name applied to a family of fruit-eating bats (*Pteropidæ*), found only in the Eastern hemisphere, and there confined to the tropical regions and Australia. It comprises 9 genera and 65 species, a considerable proportion of which occur in the islands of the Malay Archipelago. They are also found throughout Africa, and extend northward and eastward to China and Japan, and southward to Tasmania. They are likewise included among the few indigenous mammals of the South Sea Islands, being found in Samoa and the Marianne Islands. The flying foxes are the largest of the bats, the kalong of Java (*Pteropus edulis*) measuring nearly a foot and a half in length, and having an expanse of wing-membrane measuring nearly five feet across. The flesh of this species is esteemed a delicacy in many parts of Malaya; but its use in this respect by no means compensates for the enormous amount of fruit which it destroys. The flying foxes are gregarious, nocturnal animals, suspending themselves during the day head downwards by thousands from the branches of trees, where, with their wings gathered about them, they bear some resemblance to huge, shrivelled-up leaves, or to clusters of some peculiar fruit. In Batchian, according to Wallace, they suspend themselves chiefly from the branches of dead trees, where they are easily caught or knocked down by sticks, the natives carrying them home in basketfuls. They are then cooked with abundance of spices, and "are really very good eating, something like hare." Towards evening these bats bestir themselves, and fly off in companies to the village plantations, where they feed on all kinds of fruit, and so numerous and voracious are they, that no garden crop has much chance of being gathered which is not specially protected from their attacks. The flying fox of India (*Pteropus medius*) is a smaller species, but is found in great numbers wherever fruit is to be had in the Indian peninsula. Of this species Mr. Francis Day, who has had special opportunities of studying it, says—"In their diet they are exclusively frugivorous, and they do very great injury to cocoa-nut plantations and mango gardens. Their habits are very intemperate, and they often pass the night drinking the toddy from the chatties in the cocoa-nut trees, which results either in their returning home in the early morning in a state of extreme and riotous intoxication, or in being found the next day at the foot of the trees sleeping off the effects of their midnight debauch." No fossil fox bats have yet been found.

FOGARAS, the capital of an Hungarian county of the same name, in Transylvania, is situated on the left bank of the river Aluta, 55 miles east of Hermannstadt, 45° 47′ N. lat., 24° 54′ E. long. Among the principal buildings are a Franciscan monastery, five churches, and a county courthouse. The population in 1870 amounted to 4714. It was near this town that Bem was defeated by the Russian generals Engelhardt and Lüders on the 12th July, 1849. The county of Fogaras lies on the Wallachian frontier, between the county of Brassó or Cronstadt on the east, and that of Nagy Szeben or Hermannstadt on the west. The climate being cold, and the surface of the country for the most part mountainous and unfavorable to agriculture, the inhabitants are chiefly employed in rearing cattle. The population of the old district in 1870 amounted to 82,852, of whom the greater number were Wallachians, the remainder being Saxons and Hungarians. The transformation of the district of Fogaras into a county took place in 1876.

FOGELBERG, Benedict Erland (1786-1854), a Swedish sculptor, was born at Gothenburg in 1786. His father, a copper-founder, encouraging an early-exhibited taste for design, sent him in 1801 to Stockholm, where he studied at the school of art. There he came much under the influence of the sculptor Sergell, who communicated to him his own enthusiasm for antique art and natural grace. Fogelberg worked hard at Stockholm for many years, although his instinct for severe beauty rebelled against the somewhat rococo quality of the art then prevalent in the city. In 1818 the grant of a Government pension enabled him to travel. He studied from one to two years in Paris, first under Pierre Guerin, and afterwards under the sculptor Bosio, for the technical practice of sculpture. In 1820 Fogelberg realized a dream of his life in visiting Rome, where the greater part of his remaining years were spent in the assiduous practice of his art and the careful study and analysis of the works of the past. Visiting his native country by royal command in 1854, he was received with great enthusiasm, but nothing could compensate him for the absence of those remains of antiquity and surroundings of free natural beauty to which he had been so long accustomed. Returning to Italy, he died suddenly of apoplexy at Trieste, December 22, 1854. The subjects of Fogelberg's earlier works are mostly taken from classic mythology. Of these, Cupid and Psyche, Venus entering the Bath, A Bather (1838), Apollo Citharede, Venus and Cupid (1839), and Psyche (1854) may be mentioned. His native Scandinavian mythology forcibly engaged the attention of Fogelberg, and in his representations of that mythology he showed, perhaps for the first time, that he had powers above those of intelligent assimilation and imitation. His Odin (1831), Thor (1842), and Balder (1842), though influenced by his study of Greek art, still display considerable power of independent, self-reliant imagination. His portraits and historical figures, as those of Gustavus Adolphus (1849), of Charles XII. (1851), of Charles XIII. (1852), and of Birger Jarl, the founder of Stockholm (1853), are faithful and dignified works. Thirty-eight copperplate engravings of Fogelberg's works, with a portrait and biographical notice, were published by M. Casimir Leconte, Paris, 1856.

FOGGIA, a city of Italy, capital of the province of Capitanata, situated near the centre of the great plain of Apulia, 122 miles by rail E.N.E. of Naples. It is well built, and the main streets are wide and clean. The principal church, originally a stately Norman edifice, was almost destroyed by an earthquake in 1731, and the upper part has been rebuilt in a different style, which greatly injures the effect. There are numerous other churches, a fortified palace, now in ruins, a large theatre, a customhouse, an orphanage, a college for daughters of the nobility, a public library, an agricultural society, an economical society, an ornithological museum, and an artesian well. The town has now become a great railway junction, just as it was formerly the meeting-place of the principal roads of the country. It is a staple market for corn and wool, and one of the largest fairs of southern Italy is held there in May. The corn magazines or *fosse* are very extensive, consisting of vaults lined with masonry under the principal streets and squares. Other articles of export are capers, wine, and oil. The flocks of sheep that descend annually in autumn from the mountains of Abruzzo into the plains of Apulia pay a toll as they pass through the city. The population in 1872 was 34,181.

Foggia was probably founded in the 9th century, and it is supposed that it occupied the site of the ancient Arpi or Argyripa, and derives its name from the *foveæ* or pits that were dug among the ruins. It was a favorite residence of Frederick II., who in 1240 held a parliament within its walls; and there he lost his third wife, Isabella, daughter of King John of England. In 1254 Manfred, the natural son of Frederick, defeated the forces of Pope Innocent IV. outside the city, which was not long afterwards laid in ruins by Charles of Anjou. Ferdinand I. summoned his barons and prelates to Foggia to prepare a crusade against the Turks.

FOIL, thin silvered sheet-copper, highly polished, and coated with mixtures of isinglass and transparent colors, is employed by jewellers to place at the back of paste and inferior stones to improve their tints and lustre. Copper foil, known also as Nuremberg or German foil, is made from thin hammered copper plates by heating between sheets of iron, boiling in solution of tartar and salt, drying, hammering, and lastly polishing with whiting on a convex smooth surface of copper.

FOIX (Lat. *Fuxum*), a town of France, capital of an arrondissement, and also of the department of Ariége, is situated on the left bank of the Ariége, in the gorge of a narrow valley at the foot of the Pyrenees, 44 miles south of Toulouse. It is badly built, and its streets are uneven and irregular. In the middle of the town rises the old castle of the counts of Foix, situated on a rock 50 feet high, and possessing three fine towers, all anterior to the 15th century. The principal industries of the town are connected with the manufacture of iron, but there are also breweries, tanneries, and dye works. Foix is the seat of a tribunal of justice of the first instance, and possesses a communal college, a teachers' seminary, a library connected with the prefecture, a prison, and a correction house. The population in 1876 was 5127.

FOIX, Counts of, an ancient French family which flourished from the 11th to the 16th century. The title was first assumed by Roger, nephew of Peter Roger count of Carcassonne, on his inheriting the town of Foix with the adjoining lands from his uncle. He died in 1064, and was succeeded by his brother Peter, who died in 1070 and was succeeded by his eldest son Roger II. This count was excommunicated by Pope Pascal II. for taking possession of ecclesiastical property, but in 1095 he took part in the crusade, and afterwards by rich donations made his peace with the church. He died in 1125, and was succeeded by Roger III., who on his death in 1141 was succeeded by his eldest son Roger Bernard I. Roger Bernard was succeeded in 1188 by his only son Raymond Roger, who in 1190 accompanied Philip Augustus to the Holy Land, and distinguished himself at the capture of Acre. He was afterwards engaged in the wars of the Albigenses, and on his being accused of heresy, Simon de Montfort was put in possession of his estates. He, however, made his peace with the church some time before his death, which took place in 1223 from exposure and fatigue at the siege of Mirepoix. This count was a patron of the Provençal poets, and reckoned himself one of their number. He was succeeded by his son Roger Bernard II., surnamed the Great, who distinguished himself in the wars against the Albigenses, joined in an alliance against Louis VIII. of France, lost his lands but succeeded in regaining them, was twice excommunicated but obtained absolution, and died in 1241 in the abbey of Bolbone, where he was for a short time a monk. Roger IV., his son and successor, did homage for his lands to the king of France and the count of Carcassonne. He died in 1265. His son and successor, Roger Bernard III., was more famous as a poet than a warrior. He was taken prisoner by Philip the Bold and again by Peter III. of Aragon; and before his death in 1302 began the quarrel of the house of Foix with that of Armagnac. His son and successor, Gaston I., continued the war, was excommunicated in 1308 by Clement V. and imprisoned in the Châtelet, Paris, but, regaining his freedom shortly afterwards, joined Louis X. in 1315 in the expedition against Holland, and died on the way home. To him succeeded his eldest son Gaston II., who became reconciled with the house of Armagnac, joined the Navarrese in their wars against the Castilians, over whom he won a great victory at Tudela in 1335, took part in the war of the French against the English in 1337, and in 1343 assisted Alphonso XI. of Castile against the Moors. He died at Seville in September of the same year. His son Gaston III. (1331–1391), surnamed on account of his beauty Phœbus, was the most famous of the old Foix family. He took part in the wars against the English in 1345, and was on that account appointed by the king of France governor of Languedoc and Gascony. In 1346 he married Agnes of Navarre, but on account of a dispute with her brother Charles the Bad, he divorced her in 1373. On suspicion of being concerned in a conspiracy in conjunction with his brother-in-law he in 1356 suffered a short imprisonment in the Châtelet. After obtaining his release he took part in the wars against the heretics of Prussia, and on his return in 1358 he assisted in releasing the royal princesses from the hands of the Jacquerie at Meaux. In the same year he recommenced the quarrels with the house of Armagnac, and took the count of Armagnac prisoner at the battle of Launac in 1372. In 1380 he was again appointed governor of Languedoc by Charles V., but that king dying the same year the regency replaced the count of Foix by the duke of Berry. Gaston defeated and slew the duke, but was afterwards induced to resign his claims. In 1390 Gaston entertained Charles VI. in his castle of Mazères, and agreed for a sum of money to make him heir of his dominions. He died suddenly of apoplexy the same year when returning from the chase. Shortly after his death Charles VI. ceded the estate of Foix to Matthew, great-great-grandson of Roger I., who died without issue in 1398. On his death his sister's husband Archambault de Grailly took possession of the estates, and in 1401 assumed the title. Dying in 1412 he was succeeded by his son Jean de Grailly, who became governor-general of Languedoc, Auvergne, and Guienne, and, dying in 1436, was succeeded by his son Gaston IV., who took part in the wars of Charles VII. against the English, and was raised to the peerage of France. Gaston's father-in-law, Jean II. of Navarre, declared him in 1455 his successor; and Louis XI. conferred on him the seignory of Carcassonne and the countships of Roussillon and Cerdagne. In 1471 he joined in a league against Louis, which, however, was rendered abortive by the death of the king's brother. On the death of Gaston in 1472, the house of Foix became merged in that of Navarre.

FOIX, Gaston de. See Nemours.

FOIX, Paul de (1528–1584), a French prelate and diplomatist, was born in 1528. He studied Greek and Roman literature at Paris, and jurisprudence at Toulouse, where, shortly after finishing his curriculum, he delivered a course of lectures on civil law, which gained him great reputation. At the age of nineteen he was named councillor of the *parlement* of Paris. Having in this capacity expressed himself favorable to the adoption of mild measures in regard to certain persons accused of Lutheranism, he was arrested, but escaped punishment, and subsequently regained the favor of the French court. At the end of 1561 he was sent ambassador to England, where he remained four years, and in 1565 endeavored in vain to persuade Elizabeth to consent to the surrender of Havre to the French. He was afterwards sent to negotiate a marriage between Elizabeth and the duke of Anjou. On account of his former toleration of the Lutherans, Foix only with difficulty escaped perishing in the Massacre of St. Bartholomew in 1572; but having been sent in 1573 on an embassy to Italy, he was admitted to an audience of the pope, and succeeded in thoroughly establishing his reputation for orthodoxy. In 1576 he was made archbishop of Toulouse. He was afterwards employed by the king of France on various important missions, and in 1579 was appointed ambassador to Rome, where he remained till his death in 1584.

Les Lettres de Messire de Paul de Foix, archevesque de Toloze et ambassadeur pour le roy auprès du pape Grégoire XIII., au roi Henry III., were published in 1628, but there are some doubts as to their authenticity.

FOKSHAN, or Fokshani, a town of Roumania, is situated 104 miles N.E. of Bucharest on the river Milkov, which forms the boundary line between Wallachia and Moldavia—the larger portion of the town being in Wallachia. It possesses a normal school, and is the seat of a prefecture and of a criminal and district court of justice. It has a considerable trade in corn with Galatz, and is in the vicinity of the district which produces the best Moldavian wine. A congress between Russian and Turkish diplomatists was held near the town in 1772. In the neighborhood the Turks suffered a severe defeat from the Austrians and Russians in 1789. The population in 1873 was 20,323.

FOLARD, Jean Charles de (1669–1752), a French writer on military tactics, was born at Avignon, 13th February, 1669. His military ardor was first awakened by reading Cæsar's *Commentaries*, and became so strong that he twice made his escape from parental control, the second time being successful in obtaining the fulfilment of his wishes. When he joined the army he was only sixteen years of age, but the zeal with which he studied the scientific department of his profession soon brought him into notice, and in 1702 he became aide-de-camp to the duke of Vendôme, who was then in command of the French forces in Italy. For his services with the duke's brother in Lombardy in 1705 Folard received the cross of St. Louis, and in the same year he distinguished himself at the battle of Cassano, where he was severely wounded. In 1706 he defended Modena against Prince Eugene. He was dangerously wounded at the battle of Malplaquet, and a few months afterwards was taken prisoner by the Austrians. In 1711 he was appointed governor of Bourbourg, and he afterwards entered the service of Charles XII. of Sweden, and accompanied him in the invasion of Norway; but after the death of Charles he returned to France, and served as colonel in the Spanish campaign of the duke of Berwick. On the conclusion of peace he applied himself with renewed diligence to the study of military tactics, and expounded his views in the following works:—*Nouvelles Découvertes* *sur la Guerre*, 1724; *Commentaires sur Polybe*, 1727; and *Fonctions et Devoirs d'un Officier de Cavalrie*, 1733. The system of column formation advocated by Folard, and many of his other opinions, have met with nothing but ridicule from tacticians; but Frederick the Great, while condemning his general system of tactics, nevertheless published an abridgment of his works, under the title of *Esprit du Chevalier Folard*, 1761, in the preface to which he expressed a high opinion of the sagacity of Folard's criticism of certain French generals, strongly recommended many of his tactical rules and methods of defence, and admitted that even in his most visionary plans hints were to be found very valuable and suggestive. Folard died at Avignon in 1752.

See *Mémoires pour servir à l'histoire de la vie du Chevalier Folard*, 1753.

FOLDVÁR, or **DUNA FÖLDVÁR** (Danube Földvár), a town of Hungary in the county of Tolna, on the right bank of the Danube, 48 miles south of Buda, 46° 48′ N. lat., 18° 45′ E. long., is situated partly on the crest and partly on the side of a hill. Among the principal buildings are a circuit judge's court, customs office, barracks, four churches, a Franciscan monastery, and a high school. Földvár, on account of its position, is an important steampacket station, and carries on a considerable trade in wood for building purposes by means of the Danube; it is moreover a dépôt for salt, and has an extensive sturgeon fishery. The surrounding country is fertile both in corn and wine, and the inhabitants are much engaged in agricultural and commercial pursuits, fruit-growing, the manufacture of pottery, and fishing. The town, which is a domain of the university of Pesth, had formerly strong fortifications, of which some remains still exist. In the revolution of 1848–49 Földvár was considered an important strategical position, on account of its commanding the communications between the upper and lower Danube. In 1869 the population was 12,382.

FOLENGO, TEOFILO (1491–1544), otherwise known as Merlino Coccajo or Cocajo, one of the principal macaronic poets of the 16th century, was born of noble parentage at Cipada near Mantua, November 8, 1491. From his infancy he showed great vivacity of mind, and a remarkable cleverness in making verses. At the age of sixteen he entered the monastery of Monte Casino near Brescia, and eighteen months afterwards he became a professed member of the Benedictine order. For a few years his life as a monk seems to have been tolerably regular, and he is said to have produced a considerable quantity of Latin verse, written, not unsuccessfully, in the Virgilian style. About the year 1516 he forsook the monastic life for the society of a wellborn young woman named Girolama Dieda, with whom he wandered about the country for several years, often suffering great poverty, having no other means of support than his talent for versification. His first publication was the *Merlini Cocaii Macaronicon*, which relates the adventures of a fictitious hero named Baldus. The coarse buffoonery of this work is often relieved by touches of genuine poetry, as well as by graphic descriptions and acute criticisms of men and manners. Its macaronic style is rendered peculiarly perplexing to the foreigner by the frequent introduction of words and phrases from the Mantuan patois. Though frequently censured for its occasional grossness of idea and expression, it soon attained a wide popularity, and within a very few years passed through several editions. Folengo's next production was the *Orlandino*, an Italian poem of eight cantos, written in rhymed octaves. It appeared in 1526, and bore on the title-page the new pseudonym of Limerno Pitocco (Merlin the Beggar) da Mantova. In the same year, wearied with a life of dissipation, Folengo returned to his ecclesiastical obedience; and shortly afterwards wrote his *Chaos del tri per uno*, in which, partly in prose, partly in verse, sometimes in Latin, sometimes in Italian, and sometimes in macaronic, he gives a veiled account of the vicissitudes of the life he had lived under his various names. We next find him about the year 1533 writing in rhymed octaves a life of Christ entitled *L'Umanità del Figliuolo di Dio*; and he is known to have composed, still later, another religious poem upon the creation, fall, and restoration of man, besides a few tragedies. These, however, have never been published. Some of his later years were spent in Sicily under the patronage of Don Fernando de Gonzaga, the viceroy; he even appears for a short time to have had charge of a monastery there. In 1543 he retired to Santa Croce de Campesio, near Bassano; and there he died on the 9th of December in the following year. Among writers of macaronics Folengo undoubtedly holds a very high place; nor has his title to the name of poet been disputed even by his most hostile critics. He is frequently quoted and still more frequently copied by that other Benedictine, his great French contemporary, Rabelais. The earlier editions of his *Opus Macaronicum* are now extremely rare. The often reprinted edition of 1530 exhibits the text as revised by the author after he had begun to amend his life.

FOLEY, JOHN HENRY (1818–1874), sculptor, R. A., was born at Dublin, May 24, 1818. Through a distant relative, a sculptor in the city, his attention was early directed to the profession which was to occupy his life, and at thirteen he began to study drawing and modelling at the schools of the Royal Dublin Society, where he took several first-class prizes. In 1834 he proceeded to London, and in 1835 was admitted a student in the schools of the Royal Academy. He first appeared as an exhibitor in 1839 with his Death of Abel and Innocence. Ino and Bacchus, exhibited in 1840, gave him immediate reputation, and the work itself was afterwards commissioned to be done in marble for the earl of Ellesmere. Conceived entirely without classical or other affectation, this work has the charm of rare simplicity and grace. Lear and Cordelia and Death of Lear were exhibited in 1841, Venus rescuing Æneas and The Houseless Wanderer in 1842, Prospero and Miranda in 1843. In 1844 Foley sent to the exhibition at Westminster Hall his Youth at a Stream, and was, with Calder Marshall and John Bell, chosen by the commissioners to do work in sculpture for the decoration of the Houses of Parliament. Statues of John Hampden and Selden were executed for this purpose, and received liberal praise for the propriety, dignity, and proportion of their treatment. Commissions of all kinds now began to come rapidly, and without going out of his way to seek it, Foley had from this time until his death work sufficient to occupy not only the whole of his own time, but also that of the numerous assistants and pupils whom he trained. Fanciful works, busts, bas-reliefs, tablets, and monumental statues were in great numbers undertaken and executed by him with that steady equality of worthy treatment which is perhaps the next best thing to the inspiration of great genius. In 1849 he was made an associate and 1858 a member of the Royal Academy; but although until his death his name remained on the list of Royal Academicians, he, after 1861, owing, it is said, to some misunderstanding with the hanging committee of that year, ceased not only to exhibit but also to hold any communication with the body of which he was a member. Among his numerous works the following may be noticed, besides those mentioned above:—The Mother; Egeria, for the Mansion House; The Elder Brother in Comus, his diploma work; The Muse of Painting, the monument of James Ward, R. A.; Caractacus, for the Mansion House; Helen Faucit (Mrs. Theodore Martin); Goldsmith and Burke, for Trinity College, Dublin; Faraday; Reynolds; Barry, for Westminster Palace Yard; John Stuart Mill, for the Thames embankment; O'Connell and Gough, for Dublin; Clyde, for Glasgow; Clive, for Shrewsbury; Hardinge, Canning, and Outram, for Calcutta; Hon. James Stewart, for Ceylon; the symbolical group Asia, as well as the statue of the prince himself, for the Albert Memorial in Hyde Park; and Stonewall Jackson, for South Carolina. The statue of Outram is probably his masterpiece, and certainly displays more imaginative fire than any other of his works, while well exhibiting that perfect sanity of conception as well as that full mastery of the means of his art by which all his works are characterized. Foley's early fanciful works have some charming qualities; but he will probably be always best remembered for the workmanlike and manly style of his monumental portraits. His life was entirely devoted to his art, and he seems to have addressed himself to it with all the workday docility of a craftsman, and at the same time with strong feelings of duty and responsibility. Of great modesty, and rather reserved in manner, he was open to all that influences a refined nature; in poetry and music he was not only a student and admirer, but a composer and performer. He died at Hampstead of a pleuritic effusion after a short illness, preceded by a long indisposition, August 27, 1874, and was on the 4th of September buried in St. Paul's Cathedral. He left his models to the Royal Dublin Society, his early school, while a great part of his property goes eventually to the Artists' Benevolent Fund.

FOLIGNO, or Fuligno (ancient *Fulginium*), a town in the Italian province of Perugia, is situated in a beautiful and fertile valley on the Topino, 20 miles S.E. of Perugia by railway. It is an active and industrious town, its manufactures being chiefly woollen fabrics, silk, paper, wax-candles, and soap. Its principal buildings are the cathedral, the Palazzo del Governo, the Palazzo Comunale, the theatre, and the churches of S. Anna and S. Niccolò, both of which contain some fine paintings. Foligno was the seat of a school of painting, the most distinguished master of which is Niccolò Alunno, to whom a monument was erected there in 1872. Foligno is the Umbrian Fulginium, and afterwards became a Roman municipality. In the Middle Ages it was known as Fulignum, and for a long time retained its independence, but in 1281 it was destroyed by the Perugians. After it was rebuilt it was ruled by the Trinci family until 1439, when it was united to the States of the Church. In 1832, it was much damaged by an earthquake, and it suffered from the same cause, but less severely, in 1839, 1853, and 1854. The population in 1871 was 8471.

FOLKES, Martin (1690–1754), an eminent English antiquary, was born at London, October 29, 1690. At the age of seventeen he entered at Clare College, Cambridge; where he distinguished himself so much in mathematics that when only twenty-three years of age he was chosen a fellow of the Royal Society. He was elected one of the council in 1716, and in 1723 Sir Isaac Newton, president of the society, appointed him one of the vice-presidents. On the death of Newton he became a candidate for the presidency, but the higher standing and superior influence of the other candidate, Sir Hans Sloane, carried the election against him. In 1733 he set out on a tour through Italy, in the course of which he found opportunity of consulting the best furnished cabinets of that country, and composed his admirable "Dissertations on the Weights and Values of Ancient Coins," which he read before the Society of Antiquaries. Before the same society he read in 1736 his "Observations on the Trajan and Antonine Pillars at Rome," and also communicated his "Table of English Gold Coins from the 18th year of King Edward III., when gold was first coined in England, to the present time, with their Weights and Intrinsic Values." In 1745 he printed this work along with another on the history of silver coinage. He also contributed both to the Society of Antiquaries and to the Royal Society various other papers, chiefly on Roman antiquities, which were published in their transactions. In 1741 he succeeded Sir Hans Sloane as president of the Royal Society; in the following year he was made a member of the French Academy; and in 1746 was honored with the degree of LL.D. from Cambridge and Oxford. He died in 1754.

FOLKESTONE, or Folkstone, a municipal borough, seaport, and market-town of England, county of Kent, is situated on the London and South-Eastern Railway, 7 miles W.S.W. of Dover. It is very irregularly built, part of it lying in a hollow between the chalk and greensand hills, and other portions on the hills. Folkestone is much frequented in summer for sea-bathing, and steam packets ply daily between the town and Boulogne. Many of the inhabitants are engaged in the fisheries, and there is also a considerable shipping trade. The pier-harbor is 19 acres in extent, and admits vessels of 150 tons burden. In 1861 a low-water landing pier was erected, which enables passengers to land from the steamers at all states of the tide. The coast is defended by three martello towers, and a battery situated on the heights protects the town. During 1877 the number of vessels that entered the port was 885, with a tonnage of 154,897, and 854 cleared, with a tonnage of 153,208. Of these the number engaged in trade with foreign countries was—entered 46, with a tonnage of 9333; cleared 148, with a tonnage of 22,452. Among the public buildings may be mentioned the free grammar-school, the harbor-house, the town-hall and market-house, and the parish church a cruciform structure in the early Gothic style, with a tower rising from the intersection. It has recently been enlarged and restored. The original church of St. Eanswitha was built in 1095, and attached to it was a monastery for Benedictine monks, but the devastations of the sea compelled the removal of both to the cliff on which the church now stands. The monastery was destroyed at the dissolution of religious houses in 1535. At a very early period Folkestone was a place of some importance, and Roman remains have been found near it. It was one of the manors attached to the Saxon crown, and it was granted by William the Conqueror to his knight William d'Avranches, who built a Norman stronghold near the site of the old castle founded by Eadbald, king of Kent, about 630. The cliff on which these stood has been almost wholly swept away by the encroachments of the sea. In the time of Queen Elizabeth Folkestone contained only 120 houses, and it was a mere fishing village until the formation of a harbor in 1809. The opening of the railway in 1844, and the establishment of the steam packet service with Boulogne lent additional impulse to the town, and for some years it has been rapidly increasing. Harvey, the discoverer of the circulation of the blood, was born there in 1578. Folkestone unites with Hythe in returning a member to parliament. The population in 1871 was 12,694.

FOLK-LAND, or Folc-land, in early English law was the land belonging to the community at large—the *ager publicus*—as distinguished from *boc-land*, or land granted to individuals in private ownership. The conception of the land as primarily belonging to the nation or tribe appears to be universal in early civilization. As civilization advances the rights of individuals emerge and increase in importance until, as in England at the present day, the original conception has entirely disappeared. The process by which it was lost may be shortly stated as follows. (1) Grants of land were made to individuals and to religious corporations (boc-land), subject only to the *trinoda necessitas* (military service, and building bridges and fortresses). The king might hold land so granted. (2) Temporary rights over the folk-land were also granted to individuals, subject to various rent services or money payments. (3) The remaining portion of the folk-land not disposed of in this way came to be regarded as belonging to the king. Ultimately all land was said to be held of the king. Even where traces of the original conception remained in the rights of commoners the natural order was reversed, and they were regarded as deriving their right from the grant of some individual lord. While the folk-land became the *terra regis*, the private property of the king in land merged in the folk-land, and the king of England for many centuries occupied the anomalous position of being ultimate owner of all the land, and sole owner of the old folk-land, and yet, at the same time, incapable of holding land in private ownership. If a king purchased land with any private moneys of his own, it devolved upon his successor in office like the rest of the crown lands. All this, however, has now been changed. The crown lands have become public lands again, and the management of these is vested in the Commissioners of Woods, Forests, and Land Revenues; and the private estates of the sovereign are now held on the same conditions as those of ordinary persons.

FOLK-LORE. This word, formed in imitation of such German compounds as "Volksepos," "Volksfest," "Volkslied," has recently become current in the English language[1] as a convenient though somewhat vague general heading under which to arrange all that has been observed or recorded of the traditions current among the "common people" of different countries, civilized or uncivilized, whether in ancient, mediæval, or modern times. Each nation and each locality has, of course, a "folk-lore" as it has a language; and it is obvious that to set forth any given folk-lore, with all its stratifications, in a comprehensive and orderly way, would virtually be equivalent to exhibiting fully the past and present intellectual, moral, religious, and social condition of the people to whom it belonged. An exhaustive account of the folk-lores of the world would be equivalent to a complete history of the thoughts of mankind.

The eccentricities of traditionary story and traditionary practice have always been found a more or less interesting and amusing study by the contemplative observer of human nature; and almost all travellers and historians, from Herodotus downwards, have occasionally condescended to add something to the general collection of curiosities in that department. But to make a thorough investigation of the "vulgar antiquities" of any country, and especially of one's own, was, until very recently, regarded as childish and useless. An exception, indeed, was made in favor of the folk-lores of ancient Greece and Rome, as being intrinsically beautiful and exceptionally instructive. But the very fact that these had been beautified by artistic treatment impaired their usefulness from the purely antiquarian point of view; and in any case the floating traditions of Attica and Latium were too few, too fragmentary, and gathered from too narrow an area to furnish adequate data for the anthropologist and the sociologist. Here, as in so many other instances, it was necessary that men should greatly extend the area of their investigations before they could rightly understand that which alone they were curious to know.

---

[1] It was first suggested by Mr. Thoms in the *Athenæum* of 1846 (p. 862). Its equivalent does not actually occur in German.

It was in Germany that the study of folk-lore first entered upon its scientific stage. One of the earliest symptoms of the awakening of a wider and more sympathetic interest in the various products of a nation's mind, its legends and its tales, its manners and its customs, its laws, government, religion, and daily life, was the appearance in 1778–79 of Herder's celebrated collection of popular songs. But the new day was fairly ushered in by the successive publications of the brothers Grimm, more particularly of the *Kinder- und Haus-Mährchen* in 1812, and of the *Deutsche Mythologie* in 1835. The latter work, which was closely dependent on the former, showed for the first time what results may be hoped for by an intelligent investigator, if only, laying aside all prejudice, he will put himself to the trouble of collecting largely and widely, and of interpreting faithfully and rationally, a nation's oral traditions and unwritten customs. It was seen that, although many relics of the past had been irrecoverably lost, enough had been preserved to furnish conclusive proof of the oneness in faith as well as in speech of the Teutonic race, and also to give indications, in many instances, of the precise points at which the divergences had occurred. This new knowledge, derived to a large extent from the skilful use of folk-lore "collected from the mouths of old women in the spinning-rooms of German villages," acquired an altogether peculiar interest and importance from the other discovery by which the philological labors of Bopp and others had been crowned,—the discovery, namely, of the original unity of all the Aryan races, and the demonstration of the fact that the Teutons themselves were but one branch of a greater family, including Hindus and Celts, which had at one time inhabited the central plain of Asia, and before dispersing eastward and westward, had developed an ineffaceably characteristic speech, civilization, and religion. The identification verbally of Dyaus, Zeus, Jo(vi)s, Tiw, Zio, and Tyr was followed, as investigation proceeded, by the identification really of many of the strange forms in which religious sentiment had found expression; and comparative mythology became an inseparable companion of comparative philology. (See MYTHOLOGY and PHILOLOGY.) It was thenceforward obvious that every mythology, in the Aryan family at least, however puerile or absurd it might at first sight appear, was a fit subject for scientific investigation, and capable of yielding scientific results. The problem in each case was to trace the nursery tale to the legend, and the legend to the myth, and the myth to its earliest germ, and as far as possible to indicate the foreign interpolations when they occurred, and account for the local accretions. In this way the history of a story, like the history of a word, was frequently found to be more interesting and more instructive than the history of a campaign. Once this had been realized, the new field of folk-lore found many skilled laborers; and the quantity of material available for examination and classification rapidly increased. Each fresh comparison made it increasingly plain that in groundwork and plot the stories current among the Indo-European peoples were substantially identical. The reader of the fables of La Fontaine found nothing essentially and absolutely strange in the Pankatantra or Hitopadesa; the Indian ayah was discovered to have unmistakably the same stock of stories as the German, Norwegian, or Celtic nurse. In a few cases, indeed, it could be shown that the wide diffusion of some particular fable was attributable to migrations which had taken place within the historic period;[1] and in other cases it could hardly be doubted that certain very remarkable coincidences were still mere coincidences and nothing more;[2] but in a great majority of instances, it was plain that the notion of borrowing or copying having occurred was inadmissible, and that nothing could account for their constant similarity except the theory of a common origin. They were "primitive or organic legends, representing one common ancient stratum of language and thought reaching from India to Europe;" the others were secondary or inorganic, consisting of "boulders of various strata carried along by natural and artificial means from one country to another."[3]

The aboriginal Aryan legends may be arranged under one or other of two categories, the myth or the fable. That primitive fables actually exist, stories expressly invented for a moral or didactic purpose, seems a well-established fact. The fable of the King and the Bee, for example, crops up alike in India, in Greece, and in Norway, in forms that cannot be accounted for by direct oral or literary transmission;[4] and it would seem that the story of the Master-Thief (ἀρχὸς φηλητέων) which is to be met with in the Hitopadesa, in Herodotus, in the *Tales of the Alhambra*, and which is current in Norway and also in the Western Highlands of Scotland, must probably also be regarded as embodying at least a fable-germ.[5] The organic fables, however, are not so numerous as the organic myths,—those stories, that is to say, which, whether based on mistaken metaphor or distorted history, are at least the product of the unconscious play of fancy. The same characters and the same incidents constantly recur under innumerable names and shapes. "The story of the heroes of Teutonic and Hindu folk-lore, the stories of Boots and Cinderella, of Logedas Rajah and Surya Bai, are the story also of Achilleus and Oidipous, of Perseus and Theseus, of Helen and Odysseus, of Baldur, and Rustem, and Sigurd. Everywhere there is the search for the bright maiden who has been stolen away, everywhere the long struggle to recover her. The war of Ilion has been fought out in every Aryan land" (Cox). What we are accustomed to associate with the name of William Tell is told of many archers under other names, in England (William of Cloudsle), Germany, Denmark, Norway, Iceland, and Lapland;[6] the same story of the young hero dying in the fulness of youth is told of Baldur and Isfendiyar, Sifrit, and Achilles. The stories vary widely under the influence of climate, religion, and civilization, and yet remain substantially the same. The sun-myth, when transferred from southern to northern latitudes, cannot but undergo some change of shape; the *dramatis personæ* are as various in each fable as the fauna and flora of the regions in which it is told. Odin, when no longer recognized as a deity, becomes simply the wild huntsman or Hellequin; when civilization makes even such a being no longer credible, he still survives possibly as Harlequin or Robin Hood.

Hitherto the systematic study of comparative folk-lore has been almost exclusively confined within Aryan limits. But the successful application of scientific method in that field has encouraged many laborers in other regions, and an amount of material is being accumulated which may be expected ultimately to yield very important results in ethnology and anthropology. So far as the savage tribes of the world are concerned, it would seem that the greater proportion of trustworthy data is to be derived from that department of their "folk-lore" which manifests itself in traditionary practices; but in no case, indeed, can the comparative mythologist afford to overlook the qualifying or corroborative evidence supplied by what may be called comparative "ethology." Every custom has an instructive history if we can but succeed in interpreting its lore. In ascertaining when, where, and how any given tribe came first to worship plants, or animals, or ghosts, we get definitely nearer the solution of the fundamental problem of anthropology. Even the modern usages of social and domestic life, the observances that accompany such incidents as marriage, birth, and death, when skilfully read, are capable of telling us something at least of the condition of primitive man. See ANTHROPOLOGY, ANIMISM, DEMONOLOGY, FIRE, FUNERAL RITES, MARRIAGE, etc.

---

[1] See Max Müller's paper "On the Migration of Fables," in the *Contemporary Review* for 1870, republished, with additions, in *Chips from a German Workshop*, vol. iv.

[2] The Hottentots, for example, have a version of the "vestigia nulla retrorsum" fable, and a number of traces of the stories of Renard the Fox. The Zulus also have tales resembling that of Jack the Giant-Killer. See Max Müller, *Chips*, ii. 212; iv. 156. So with the large family of stories which turn on the idea of gods wandering on earth in the likeness of men.

[3] Max Müller, *Chips*, ii. 245.

[4] Max Müller, *Chips*, ii. 232; iv. 153. Sir George W. Cox also finds that the legend of "The Carter, the Dog, and the Sparrow" would never have found its way into the nurseries of German peasants if written by Grimm himself in imitation of some other Aryan tale (*Mythology of the Aryan Races*, i. 124–129, 167).

[5] Cox, *Mythology of the Aryan Races*, i. 124 *seq.*

[6] But also, it ought to be added, among Turks, Mongolians, and Samoyedes,—in other words, beyond the Aryan territory.

Literature.—The oldest professed collections of English folklore are those of Aubrey (*Miscellanies*, 1686, and frequently reprinted), and Bourne (*Antiquitates Vulgares*, 1725). The latter was incorporated by Brand in his *Observations on Popular Antiquities*, 1777, republished by Sir Henry Ellis in 1813, and again in 1841. *The Every-Day Book* of Hone appeared in 1826, and *The Year Book* in 1829. Among the more recent publications of a similar class may be mentioned the *Book of Days*, and *Popular Rhymes of Scotland*, by Chambers. Max Müller's *Essay on Comparative Mythology* was first published in 1856; Dasent's *Tales from the Norse*, with an introduction, in 1859; Campbell's *Popular Tales of the West Highlands* in 1861; Kelly's *Curiosities of Indo-European Tradition and Folk-Lore* in 1863; see also Hardwick's *Traditions, Superstitions, and Folk-Lore* (1872); and *Folk-Lore of the Northern Counties of England and the Borders*, by W. Henderson, with an appendix on Household Stories, by S. Baring-Gould (1876). As for Germany, since the publication of the *Kinder- u. Hausmährchen* (1812), and of the *Deutsche Mythologie* (1835), "the myths, the legends, the nursery-tales, the songs, proverbs, and popular customs of the Scandinavo-Germanic race have had a whole host of faithful expounders and affectionate illustrators, who have scarcely left a single foot unexplored of that vast and interesting field of tradition" (De Gubernatis). Special reference may be made to the *Deutsche Mythologie*, by Mannhardt, and to the *Zeitschrift für Deutsche Mythologie und Sittenkunde*, edited by Mannhardt and Wolf (1853–59). The collection of Norse popular tales by Asbjörnsen and Moe (1842–43) has for the most part been translated by Dr. Dasent (as above). Castrén has given an account of the mythology of Finland (*Finnische Mythologie*, edited by Schiefner); Kreuzwald of the popular tales of Esthonia (*Ehstnische Mährchen*, 1869); and Afanassieff of the folk-lore of Russia. The Slavonic mythology has been specially treated by Popoff, Kaisaroff, and Hanusch; while Osinski and Grohmann have dealt respectively with the folk literatures of Poland and Bohemia. Hahn has published a collection of *Griechische u. Albanesische Mährchen* (1864), in the introduction to which he gives forty "story-roots" (Märchen- und Sagformeln); and something has been done for the folk-lore of Rome by R. H. Busk (1874). For Spain reference may be made to Fernan Caballero; for Brittany to Villemarqué; for Iceland to Powell and Magnusson among others; for Eskimo tales to Rink. Radloff has dealt with the folk literature of the Turkish races of south Siberia; and a volume of *Kalmuck and Mongolian Traditionary Tales* was published in 1873. For Corea, see Dallet (*Église de la Corée*, 1874); for China, the works of Doolittle and Dennys; for Dardistan, Leitner; and for Southern Africa, the *Zulu Nursery Tales*, by Rev. Henry Callaway, M. D. (1866), and the *Hottentot Fables and Tales* of Dr. Bleek (1864). For American folk-lore, see Brinton's *Myths of the New World*, and Bancroft's *Races of the Pacific*. The works of Sir John Lubbock, and Messrs. Herbert Spencer, Tylor, M'Lennan, and Morgan deal largely with the folk-lore of various savage tribes. As bearing upon the general subject of comparative mythology, see the works of Kuhn, especially his *Herabkunft des Feuers und des Göttertranks* (1859); Bastian (*Der Mensch in der Geschichte*); Roth (*Ueber den Mythus von den fünf Menschen-geschlechtern*); Max Müller (*Lectures on Science of Language*, 2d series. and *Chips from a German Workshop*, vol. ii.); M. Michel Bréal (*Hercule et Cacus, Étude de mythologie comparée*, and *Le Mythe d'Œdipe*); Husson (*La Chaine Traditionelle, Contes et Légendes au point de vue Mythique*, 1874); Fiske (*Myths and Myth-makers*, 1873); and Gubernatis (*Zoological Mythology*, 1872). (J. S. BL.)

FOLLEN, AUGUST (or, as he afterwards called himself, **ADOLF**) **LUDWIG** (1794–1855), a German poet, was born at Giessen in Hesse-Cassel, January 21, 1794. He studied theology at Giessen and law at Heidelberg, and after leaving college edited the *Elberfeld Allgemeine Zeitung*. For connection, real or supposed, with some radical plots, he was imprisoned for two years at Berlin. When released in 1821 he went to Switzerland, where he taught in the canton school at Aarau, farmed from 1847 to 1854 the estate of Liebenfels in Thurgau, and then retired to Bern, where he lived till his death (26th December, 1855). Besides a number of minor poems he wrote *Harfengrüsse aus Deutschland und der Schweiz* (1823), and *Malegys und Vivian* (1829), a knightly romance after the fashion of the romantic school, edited parts of *Tristan und Isolde* and the *Niebelungenlied*, translated the Homeric Hymns in company with R. Schwenck (Giessen, 1814), *Tasso's Jerusalem Delivered* (1818), and a collection of Latin hymns and sacred poetry (Elberfeld, 1819). In 1846 he published a brief collection of sonnets entitled *An die Gottlosen Nichts-Wüthериche*. This was aimed at Ruge, and was the occasion of a literary duel between the two authors. Follen's posthumous poem *Tristan's Aeltern* (Giessen, 1857) may also be mentioned, but his best-known work is a well-executed collection of German poetry entitled *Bildersaal Deutscher Dichtung* (2 vols., 1827).

FOLLEN, CHARLES (1796–1840), brother of the preceding, was born at Romrod, in Hesse-Darmstadt, September 4, 1796. He studied theology and law at Giessen, where he acted for some time as privatdocent. His liberal sentiments and writings, and the part he took in the defence of popular rights, made him obnoxious to the Government of his own province. He accordingly went to Jena to lecture there, but the assassination of Kotzebue by Sand happened almost immediately after his arrival, and the Government believed or affected to believe that Follen was an accomplice. The inquiries that were made conclusively proved his innocence, but notwithstanding this he found it necessary to remove to Switzerland, where he taught in the cantonal school of the Grisons at Chur, and at the University of Basel. Whilst thus engaged the Prussian Government demanded his surrender as a political prisoner. Twice the Government of Basel refused, but the third request was so peremptory that they were unwillingly preparing to comply, when Follen saved himself by a hurried flight. In the beginning of 1825 he arrived in the United States, and was employed for the next ten years in teaching ecclesiastical history, ethics, and the German language and literature at Harvard College. He then acted as Unitarian clergyman at New York and East Lexington. He perished, along with 175 fellow-travellers, at the burning of the steamship "Lexington," in Long Island Sound, January 13, 1840. Follen was the author of several very celebrated and popular songs written in the interests of liberty. The best is perhaps the *Bundeslied*, beginning "Brause du Freiheitssang." It is certainly one of the most spirited odes in modern German lyric poetry. Whilst in America Follen wrote a German grammar and reader. His wife Eliza Lee (1787–1860), an American authoress of some reputation, published after his death his lectures and sermons, with a biography written by herself (5 vols., Boston, 1841).

FOLLETT, SIR WILLIAM WEBB (1798–1845), attorney-general of England, was born at Topsham in Devonshire, December 2, 1798. He was the son of Captain Benjamin Follett, who had retired from the army in 1790, and engaged in business at Topsham. His mother was an Irish lady of Kinsale. The early indications which he gave of superior abilities induced his father to bring him up for the bar. He received his early education at Exeter grammar-school, of which Dr. Lempriere, author of the well-known *Classical Dictionary*, was then head-master. After a short course of study under a private tutor, he entered, in 1814, Trinity College, Cambridge, and two years later the Inner Temple. In 1818 he took his degree of B.A. without academical honors, and the same year settled in London, becoming a pupil of Godfrey Sykes and Robert Bayley, two of the most eminent special pleaders of the day. He began to practise as a pleader below the bar in 1821, was called to the bar in 1824, and joined the western circuit in 1825. At the very outset his great qualifications were universally recognized, and his rapid rise was assured. He was thoroughly master of his profession, having devoted himself to it with exclusive zeal; and with remarkable quickness of perception he combined a solidity and ripeness of judgment such as are rarely seen in one so young. The statements current soon after his death as to the frequent interruption of his studies by ill health are emphatically contradicted by Lord Brougham. His rapid and continuous success was owing not only to his unquestionable superiority, but to his singular courtesy, kindness, and sweetness of temper. In 1830 he married the eldest daughter of Sir Ambrose Harding Gifford, chief justice of Ceylon. His reputation in Westminster Hall being solidly established, he sought in 1832 an entrance into parliament, and offered himself as candidate for the city of Exeter on the Conservative side. On this occasion he failed; but in 1835 he was returned for the same city at the head of the poll. In parliament he early succeeded in gaining the ear of the house, and attained a position of high distinction. Under the first administration of Sir Robert Peel, Follett was appointed solicitor-general (November, 1834), but resigned with the ministry in April, 1835. In the course of this year he was knighted. On the return of Peel to power in

1841 Sir William was again appointed solicitor-general, and in April, 1844, he succeeded Sir Frederick Pollock as attorney-general. But his health, which had begun to fail him in 1838, and had been permanently injured by a severe illness in 1841, now broke down, and he was compelled to relinquish practice and to visit the south of Europe. He returned to England in March, 1845; but the disease, consumption, reasserted itself, and he died in London on the 28th of June following. His death was mourned as a loss not only to the profession but to his country, and the public esteem for his character was marked by the attendance at his funeral in the Temple Church of many distinguished persons,—the lord chancellor, the first lord of the treasury, and the chief justice of the common pleas being among the pall-bearers. A noble statue of Follett, executed by Behnes, was erected by subscription it St. Paul's cathedral. (See Brougham's notice of Follett, *Works*, vol. iv.)

FONBLANQUE, ALBANY WILLIAM (1793-1872), was descended from a noble French Huguenot family, the Greniers of Languedoc. The titles of Comte de Hautserre et de Fonblanque were conferred by Henry IV. on the sons of the famous Sieur Pierre de Grenier, known in history by his gallant defence of the castle of Cessenan against the Duc de Montmorenci in 1584. After the revocation of the edict of Nantes, the Greniers underwent severe persecutions on account of their devotion to the Huguenot cause; and in 1740, Abel de Grenier, Comte de Fonblanque, sent his two sons, Antoine and Jean, to England that they might be educated in the Protestant faith. John became nationalized in this country under the name of Fonblanque; and his son, John Samuel Martin Fonblanque, a distinguished equity lawyer, and the author of a standard legal work, a *Treatise on Equity*, became the father of the most brilliant journalist of his day. The father of Albany Fonblanque was, like his son, a staunch Liberal; he represented the borough of Camelford in parliament; and throughout his career was remarkable for the integrity and courage, as well as for the ability, with which he supported Liberal principles.

The subject of the present notice was born in London in 1793. At fourteen he was sent to Woolwich to prepare for the Royal Engineers. His health, however, failed, and for two years his studies had to be suspended. Upon his recovery, he studied for some time with Chitty, the eminent special pleader, with a view to being called to the bar. Fonblanque had no inclination for law, but he valued very highly the course of training he thus obtained, and in after life maintained that a study of law should be included in a liberal education. At the age of nineteen (1812) he commenced writing for the newspapers, and very soon attracted notice both by the boldness and liberality of his opinions, and by the brilliance of his style. Fonblanque's manner of working might have lent some color to the definition of genius as an infinite capacity for taking trouble. His nephew, Mr. Edward Fonblanque, to whose biography we are indebted for the details given in this notice, tells us that in his earlier days he frequently wrote an article ten times before sending it to press, and this not from timidity or anxiety, for from the first his popularity was assured, but because his own ideal of political thought and composition was infinitely higher than that of the public.

As a result of this arduous and earnest cultivation he soon obtained sufficient popularity as a journalist to be able to renounce all idea of following law as a profession; but at the same time that he was eagerly taking his share in all the political struggles of this eventful period, he was also continuing his studies, devoting no less than six hours a day to the study of classics and political philosophy. Under this severe mental training his health once more broke down. At the age of twenty-one he had a long and dangerous illness, and continued weak and subject to nervous depression for the remainder of his life. His energy, however, was not impaired. He became a regular contributor to the newspapers and reviews, realizing a fair income, which, as his habits were simple and temperate, secured him against pecuniary anxieties. From 1820 to 1830 Albany Fonblanque was successively employed upon the staff of the *Times* and the *Morning Chronicle*, whilst he contributed to the *Examiner*, to the *London Magazine*, and to the *Westminster Review*. In 1828 the *Examiner* newspaper, which had been purchased by the Rev. Dr. Fellowes, the learned and amiable author of the *Religion of the Universe*, etc., was given over to Fonblanque's complete control; and for a period of seventeen years (1830 to 1847) he not only sustained the high character for political independence and literary ability which the *Examiner* had gained under the direction of Leigh Hunt and his brother John Hunt, but even compelled his political opponents to acknowledge a certain delight in the boldness and brightness of the wit directed against themselves. When it was proposed that the admirers and supporters of the paper should facilitate a reduction in its price by the payment of their subscription ten years in advance, not only did Mr. Edward Bulwer (Lord Lytton) volunteer his aid, but also Mr. Disraeli and Mr. Clay, M.P., who were thus voluntarily prolonging the reign and spreading the influence of the representative Radical organ. But the *Examiner* under the direction of Fonblanque did not confine itself to the sphere of politics; the fine arts, literature, and the drama occupied a due share of its attention. Amongst its contributors were such men as Thackeray, Marmion Savage, John Stuart Mill, Walter Savage Landor, Charles Dickens, etc., names which do not belong exclusively to any political party, but which, associated in the work of criticism, give firm assurance that the "discovery of the best that is known and thought in the world" (Mr. Arnold's admirable definition of the true function of literary criticism) was for once at any rate in competent and impartial hands. During his connection with the *Examiner*, Fonblanque had many advantageous offers of further literary employment; but he devoted his energies and talents almost exclusively to the service of the paper he had resolved to make a standard of literary excellence in the world of journalism. Whatever he wrote was as carefully prepared and revised as when he was only an aspirant to fame; every reference made and every anecdote used as an illustration he was careful to verify, and in Mr. E. Fonblanque's biography of his distinguished relative are given several racy answers he received from Count d'Orsay and others, concerning some witty story or saying which had taken his fancy, but which he was too scrupulous to repeat from memory. Fonblanque was offered the governorship of Nova Scotia; but although he took great interest in colonial matters, and had used every effort to advocate the more generous political system which had colonial self-government for its goal, he decided not to abandon his beloved *Examiner* even for so sympathetic an employment. In 1847, however, domestic reasons induced him to accept the post of Statistical Secretary of the Board of Trade. This of course compelled him to resign the editorship of the *Examiner*, but he still continued to contribute largely to the paper, which, under the control of John Forster, continued to sustain its influential position. During the later years of his life, Fonblanque took no prominent part in public affairs; and when he died at the age of seventy-nine (1872) he seemed, as his nephew rightly observes, "a man who had lived and toiled in an age gone by and in a cause long since established." The present generation, in the full enjoyment of those reforms he had labored so bravely and unweariedly to promote, found it difficult to realize how much had been effected by Liberals of the stamp of Albany Fonblanque, in days not so remote from our own after all, before the passing of the Reform Act, when, to quote his own words—"The Test Acts were unrepealed; the Catholics were excluded from the legislature; slavery existed in our colonies; the prestige of the perfection of the law was unbroken, and the sanguinary character of the criminal code unmitigated; the corporations were sinks of corruption; a few individuals nominated nearly half the members of the House of Commons; and a parliamentary reformer was in common acceptation another word for a visionary."

The character of Albany Fonblanque's political activity may be judged of by a study of his *England under Seven Administrations*, in comparison with the course of social and political events in England from 1826 to 1837. Although these volumes contain only articles reprinted from the *Examiner*, they give a vivid and spirited history of one of the most important and stormy phases of Parliamentary Reform. Fonblanque, although an ardent upholder of popular rights and an uncompromising opponent of bigotry and oppression, will never be found upon the side of violence or license. The Chartists received from no source more complete condemnation than from the *Examiner*, which consistently advocated the principle that moral force was in every case to be relied upon, and that the liberties of the constitution were to be enlarged by means which were also constitutional. "In describing Lord Durham's politics," says Mr. Edward Fonblanque, "he unconsciously depicted himself. He was not a reformer of the republican class, but he occupied as it were the frontier line of constitutional reform." In a word, Fonblanque was an honorable example of the constitutional Radical who follows after liberty, but uses the pathway of the law. As a journalist, he must also be regarded in the light of a reformer. Journalism before his day was regarded as a somewhat discreditable profession; men of true culture were shy of entering the hot and dusty arena lest they should be confounded with the ruder combatants who fought there before the public for hire. But the fact that Fonblanque, a man not only of strong and earnest political convictions but also of exceptional literary ability, did not hesitate to choose this field as a worthy one in which both a politician and a man of letters might usefully as well as honorably put forth his best gifts, must have helped, in no small degree, to correct the old prejudice.

Life and Labors of Albany Fonblanque, edited by his nephew, Edward Barrington de Fonblanque, 1874; *England under Seven Administrations*, by Albany Fonblanque, 1837. (J. MA.)

FOND DU LAC, a city of the United States, capital of Fond du Lac county, Wisconsin, is beautifully situated on a rising ground at the southern end of Lake Winnebago, 63 miles N.W. of Milwaukee. Railways radiate from it in various directions, and its situation on Winnebago lake gives it access to a wide district of inland navigation. It has a considerable shipping trade in wood, hay, and cattle, and possesses a large tannery, foundries, sawmills, cigar factories, carriage and wagon factories, and a railway-car factory. The water supply is obtained chiefly from artesian wells, which vary in depth from 90 to 130 feet. The population in 1860 was 5400, and in 1870, 12,764.

FONDI, the ancient *Fundi*, a town of Italy in the province of Caserta, about 11 miles N.W. of Gaeta. Its principal street lies along the Appian way, and portions of its old polygonal or Cyclopean walls are still in good preservation. The castle, now in a sadly dilapidated condition, is of interest for its connection with the Colonna family, and the Dominican convent contains a chapel which was occupied as a cell by Thomas Aquinas, and an orange-tree said to have been planted by the saint. The church of Santa Maria is a building in the Italian Gothic style, much disfigured in the interior. Between the town and the sea lies the Lago de Fondi or *Lacus Amyclanus*, in the midst of a marshy tract which has recently been greatly diminished by draining; and near this is a cave, where, according to Tacitus, Sejanus saved the life of Tiberius. The district was in ancient times famous for its wine, including the Ager Cæcubus, which gave its name to the Cæcuban of the Latin poets. Population in 1871, 6632.

Fundi was probably at first a Volscian town. Its citizens were rewarded in 190 B.C. with full Roman citizenship, and enrolled in the Æmilian tribe. Under Augustus it received a colony of veterans. In the time of the barbarian invasions it suffered severely, more especially from the Saracens in 845. The election of the anti-pope Clement VII. took place in the town in 1378, and in 1534 it was attacked and plundered by the Turkish corsair Barbarossa, who was anxious to capture the beautiful countess Giulia Gonzaga as a present for the sultan.

FONT (Lat. *fons*, It. *fonte*, Fr. *fonts*), the vessel used in churches to hold the water for Christian baptism. The modes of administering baptism have varied at different periods of the existence of the Christian churches, causing corresponding changes in the forms and auxiliaries of the receptacle of the consecrated water. There is reason to believe that in the times of the apostles and early missionaries the rite was administered by sprinkling, as whole multitudes of people, and even whole kingdoms, were baptized in one day. But a very general method in early times was no doubt that of total immersion, the catechumens being received by the priest in the water. As Christianity became more general of course fewer adults would present themselves for baptism, and consequently the size of the vessel would not need to be beyond what would allow of the total immersion of an infant. In fact down to the time of the Reformation fonts continued to be made quite large enough to allow of the total immersion of infants, and there is little doubt that down to that date the method was occasionally employed. Baptism by infusion and by aspersion followed this method, though they were no doubt used concurrently, and in a sense combined, for in certain representations of the rite in illuminations and stained glass the infant is represented as seated naked in the font, while from a vessel the priest pours the water upon the head. Originally used only for sick or infirm persons, the method of baptism by infusion became gradually the established practice, and all doubts as to its validity were removed by appeal to papal and other high authority.

In early times the font was placed in the baptistery, a structure often entirely separate from the body of the church, of which the celebrated Baptistery at Florence is the finest example. In these the well or basin for containing the water was usually reached by descending steps. The baptisteries were round, square, octagonal, or crosslike in form, and in design bear the impress of the period to which they belong. Few are found of late date, and the only existing structure at all recalling them in English churches is found at Luton in Bedfordshire. The font at Luton belongs to the Decorated style of English art, and is inclosed in an octagonal structure of freestone, consisting of eight pillars about 25 feet in height, supporting a canopy. The space around the font is large enough to hold comfortably half a dozen people. At the top of the canopy is a vessel for containing the consecrated water, which when required was let down into the font by means of a pipe. The space around the font in the ancient baptisteries was of size to admit several catechumens at the same time; and not only was the whole rite of baptism performed within them, but that of the holy eucharist likewise, and even the baptism of infants. As baptism was administered in early times by bishops only, baptisteries were rare except at the principal church of the diocese. Easter, Whitsuntide, and Epiphany were the principal seasons of its administration. In the 9th century fonts became general in all churches, and baptism was performed at all times by priests of all ranks.

Of fonts still in existence few are older than the 11th century. The material in the Western Church was generally stone, and the outsides and accessories are frequently ornamented with some of the loveliest and most characteristic of the national arts of the Middle Ages. In the Eastern Church it was different. "The font, κολυμβήθρα," says Neale (*Eastern Church*, i. 214), "in the Eastern Church is a far less conspicuous object than it is in the west. Baptism by immersion has been retained; but the font seldom or never possessed any beauty. The material is usually either metal or wood. In Russia the columbethra is movable, and only brought out when wanted." The proper material for fonts in the Western Church was hard stone, as marble, porphyry, or granite. Fonts of bronze and lead are, however, sometimes found, and the basins of many stone fonts were lined with lead to prevent the absorption of the water by the porous stone. A font shaped from one block of oak is in the church at Evenechtyd, Denbighshire. Continental fonts bear distinctly the impress of the time to which they belong. They appear very early, ornamented with bas-reliefs, columns, and arches, as well as with the characteristic details of the ornamentation of their period. Representations of St. John the Baptist are very common. At Pont-à-Mousson on the Moselle, one bears bas-reliefs of that saint preaching in the wilderness, and of the baptism of Christ, executed with that simple sincerity which is more valuable than the highest refinement and finish in design and execution. In the 11th and 12th centuries cup-shaped and cylindrical forms were most common, either as simple cylinders and truncated cones or supported by one or more pillars. Frequently the basin is hollowed out of one large square or oblong slab, supported at the centre by a broad column, with auxiliary columns at the corners, all bearing the mouldings and ornaments characteristic of the period. Caryatids sometimes take the place of the pillars, and sculptured animals and other grotesques of curious design sometimes form the bases. Octagonal forms are not altogether absent from this period, and even hexagons have been occasionally found. Pentagons are very rare. The font, however, at Cabourg, on the north coast of France, is formed of a pentagonal block rather bare of ornamentation, and supported by a group of columns. In the 13th century octagonal forms became more prevalent, although the earlier kinds were not discontinued.

The very remarkable font at Hildesheim in Hanover belongs to the 13th century, and is in complete preservation. The basin rests upon the shoulders of four kneeling figures, each bearing a vase from which water is running, emblematic of the four rivers of Paradise. Above is an inscription which explains the connection of these rivers with the virtues temperance, courage, justice, and prudence. On the sides of the cup itself are bas-reliefs representing the Passage of the Jordan, the Passage of the Red Sea, the Baptism of Christ, and the Virgin and Child. These are separated by columns, by scrolls bearing inscriptions, and by medallions with figurative heads of the abstract virtues named above, and with heads of the prophets. The font has a conical lid, similarly ornamented, and bearing also four bas-reliefs. A cast of this font is now in the South Kensington Museum. At Mayence the font, which belongs to about the year 1328, is of lead, and bears images of the Saviour, the Virgin, St. Martin, and the Twelve Apostles.

Cylindrical fonts become much more rare in the 14th century, the almost universal shape being the octagon. In the 15th and 16th centuries the most elaborate and remarkable of Continental fonts were produced, and some are indeed works of the highest art in sculpture. This superiority is probably more due to increased delicacy and moderation of design, than to any great change in the shape or in the mode of attaching ornament. In early fonts, though the exterior is polygonal, the cup itself is generally circular; but it is characteristic of the 15th century fonts that the octagonal form is carried out even in the cup. The fonts at Strasburg, Freiburg, and Basel are examples of this. Few if any English fonts date from before the Conquest, but a great number of Norman fonts, perhaps more than of any other period before the Reformation, are still in existence, and form some of the most characteristic of the architectural remains of the time. In form circular or square, they are generally supported on one or more columns, and are ornamented with bas-reliefs, net-work of columns and arches, grotesques, rude foliage, niches with figures, and many other forms. Good examples of Norman fonts may be seen at Lincoln Cathedral; Iffley, Oxon; Newenden, Kent; Coleshill, Warwickshire; East Meon, Hants; and Castle Frome, Herefordshire. In the Late Norman and Early English periods, octagonal fonts became common, and with few exceptions this form continued in use until the Reformation. Early English fonts are comparatively rare. They bear the moulding, foliage, and tooth ornament in the usual style of the period. A good example of an Early English font is at All Saints, Leicester; others may be seen at St. Giles, Oxford, and at Lackford, Suffolk. Fonts of the Decorated period are also less common than those of the precedent Norman or subsequent Perpendicular periods, but are superior in detail and execution to those of any other stage of our art. Fonts of the Perpendicular period are very common, and are generally raised upon steps, which, together with the body of the font, are frequently richly ornamented with panelling. It was also the custom during this period to ornament the font with shields and coats of arms, and other heraldic insignia, as at Herne, Kent.

Leaden fonts of Norman date are found at Dorchester, Oxon, at Avebury, Wilts, and other places. In Holyrood Chapel there was a brazen font in which the royal children of Scotland were baptized. It was carried off in 1544 by Sir R. Lea, and given by him to the church at St. Alban's, and was afterwards destroyed by the Puritans. A silver font was at Canterbury, which was sometimes brought to Westminster on the occasion of a royal baptism. At Chobham, Surrey, there is a leaden font covered with oaken panels of the 16th century.

In 1236 it was ordered by Edmund, archbishop of Canterbury, that baptismal fonts should be kept under lock and key, as a precaution against sorcery: "Fontes baptismales sub sera clausi teneantur propter sortilegia." The lids appear at first to have been quite simple and flat. They gradually, however, partook of the ornamentation of the font itself, and are often of pyramidal and conical forms, highly decorated with finials, crockets, mouldings, and grotesques. Some very rich font covers may be seen at Ewelme, Oxon; St. Gregory, Sudbury; North Walsingham, Norfolk; Worlingworth, Suffolk. The ordinary position of the font in the church was near the entrance, usually to the left of the south door.

FONTAINE, JEAN DE LA. See LA FONTAINE.

FONTAINE, PIERRE FRANÇOIS LÉONARD (1762–1853), French architect, was born at Pontoise, September 20, 1762. He was of a family several of whose members had distinguished themselves as architects, and he early showed the taste and the ability which promised to revive in his person the family distinction. Leaving the college of Pontoise at the age of sixteen he was sent to L'Isle-Adam, to assist in hydraulic works undertaken by the architect André. To facilitate his improvement André allowed him to have access to his plans and to copy his designs. At this time he formed a friendship with another young student of his art, Thibaut, whose passion quickened his own. In October, 1779, he was sent to Paris to study in the school of Peyre the younger, and there began his acquaintance with Percier, which ripened into a life-long friendship. After six years of study he competed for a prize at the Academy, and, winning the second, received a pension and was sent to Rome (1785). Percier accompanied him. The Revolution breaking out soon after his return to France, he took refuge in England; but after the establishment of the consulate, he was employed by Bonaparte to restore the palace of Malmaison. Henceforth he was fully engaged in the principal architectural works executed in Paris, as architect successively to Napoleon I., Louis XVIII., and Louis Philippe. In conjunction with Percier (till his death) he was employed on the Arch of the Carrousel, the restoration of the Palais-Royal, the grand staircase of the Louvre, and the works projected for the union of the Louvre and the Tuileries. In 1812 he was admitted a member of the Academy of Fine Arts, and in 1813 was named first architect to the emperor. With Percier he published the following works,—*Palais, Maisons, et autres Édifices Modernes dessinés à Rome* (1798); *Description des Fêtes et Cérémonies du Mariage de Napoléon et de Marie Louise* (1810); and *Recueil de Décorations Intérieures* (1812). Fontaine lost his friend and associate Percier in 1838, and died himself at Paris, October 10, 1853.

FONTAINEBLEAU, a town of France, at the head of an arrondissement, in the department of Seine-et-Marne, about 37 miles S.E. from Paris on the railway to Lyons, in 48° 24′ 23″ N. lat. and 2° 42′ 1″ E. long. It stands in the midst of the forest of Fontainebleau, is well built, and has broad, clean, handsome streets. Among the more important buildings and institutions are the hôtel de ville, the barracks, the court-house, two hospitals, a college, and a public library. The Pompadour mansion, and a portion of that which belonged to the cardinal of Ferrara, are still preserved; and a statue of General Damesme adorns the principal square. Wood-turning and the manufacture of porcelain and earthenware are the chief industries; and wine, grapes, garden produce, and paving-stones are articles of export. The population in 1871 was 11,545. In the immediate vicinity of the town is the celebrated palace of Fontainebleau—one of the largest, and in the interior one of the most sumptuous, of the royal residences of France. The origins of the name and of the building are equally unknown; but the old manor-house was used by Louis VII. in the latter part of the 12th century, and continued a favorite residence of Philip Augustus and St. Louis. The existing edifice was begun by Francis I., who laid out immense sums of money in its erection, employing Primaticcio, a famous Italian architect, to draw the plans, and commissioning Leonardo da Vinci, Andrea del Sarto, and Benvenuto Cellini to expend the resources of their arts in making it a truly royal residence. Henry IV. doubled the area of the buildings and gardens, adding, among other portions, the great Diana gallery, the Court of the Princes, and the Galerie des Cerfs. A canal which he constructed was afterwards filled up by Louis XIV. With Louis XV. the palace fell into disfavor, and for a time it was used as a military school. Napoleon I. restored it with great splendor, at a cost of 6 million francs, and often resided in it; but after the return of the Bourbons it was again allowed to fall into disrepair. Louis XVIII. and Louis Philippe both did somewhat to its restoration. The congeries of buildings is very extensive, the roofing, it is said, covering no less than 14 acres. There are five great courts, distinguished as the Court of the White Horse, the Court of the Fountain, the Oval or Donjon Court, the Court of Princes, and the Court of the Kitchens or of Henry IV. The first is also called the Court of Adieux, in memory of the parting scene between Napoleon and his Old Guard in 1814, at the foot of the Horse Shoe staircase. The chapel of the Holy Trinity was built under Francis I., and the chapel of St. Saturnin dates from the same period, and occupies the site of an older building which was consecrated by Thomas à Becket. It is impossible to do more than mention a few of the historical events which have taken place at Fontainebleau. Philip the Fair, Henry III., and Louis XIII. were all born in the palace, and the first of these kings died there. James of Scotland was there received by his intended bride; and Charles V. of Germany was entertained there in 1539. Christina of Sweden lived there for years, and the gallery is still shown where she caused her secretary Monaldeschi to be murdered, or, as she regarded it, executed. In 1685, Fontainebleau saw the signing of the revocation of the edict of Nantes, and in the following year the death of Condé. In the 18th century it had two illustrious guests in Peter the Great of Russia and Christian VII. of Denmark; and in the early part of the 19th it was twice the residence of Pius VII.,—in 1804, when he came to consecrate the emperor, and in 1812–1814, when he was that emperor's prisoner. It was within its walls that the sentence of divorce was passed against Josephine. The forest of Fontainebleau is one of the most beautiful wooded tracts in France, and for generations it has been the chosen haunt of French landscape painters. The most celebrated spots are the Vallé de la Solle, the Gorge au Loupe, the Gorge d'Apremont, and the Fort l'Empereur. The whole area extends to 81,740 acres, and it is traversed by 12,000 miles of road and pathway.

See Pfnor, *Monographie de Fontainebleau*, with text by Champollion Figeac, Paris, 1866.

FONTANA, Domenico (1543–1607), Italian architect and mechanician, was born at Mili, a village on the lake of Como, in 1543. After a good training in mathematics, he went in 1563 to join his elder brother, then studying architecture at Rome. He made rapid progress, and was taken into the service of Cardinal Montalto, for whom he erected a chapel in the church of Santa Maria Maggiore and the villa Negroni. When the cardinal's pension was stopped by the pope, Gregory XIII., Fontana volunteered to complete the works in hand at his own expense. The cardinal being soon after elected pope, under the name of Sixtus V., he immediately appointed Fontana his chief architect. Amongst the works executed by him were the Lateran Palace, the palace of Monte Cavallo (the Quirinal), the Vatican Library, etc. But the undertaking which brought Fontana the highest repute was the removal of the great Egyptian obelisk, brought to Rome in the reign of Caligula, which was lying in the circus of the Vatican, and its erection in front of St. Peter's. This he accomplished in 1586. After the death of Sixtus V., charges were brought against Fontana of misappropriation of public moneys, and Clement VIII. dismissed him from his post (1592). This appears to have been just in time to save the Colosseum from being converted by Fontana into a huge cloth factory, according to a project of Sixtus V. Fontana was then called to Naples, and accepted the appointment of architect to the viceroy, the count of Miranda. At Naples he built the royal palace, constructed several canals, and projected a new harbor and bridge, which he did not live to execute. The only literary work left by this architect is his account of the removal of the obelisk, 1589. He died at Naples in 1607, and was honored with a pompous funeral in the church of St. Ann.

FONTANA, Lavinia (1552–1614), daughter of Prospero (see below), was a painter of no little fame, especially in portraits. She was greatly employed by the ladies of Bologna, and, going thence to Rome, painted the likenesses of many illustrious personages, being under the particular patronage of the family (Buoncampagni) of Pope Gregory XIII., who died in 1585. The Roman ladies, from the days of this pontiff to those of Paul V., elected in 1605, showed no less favor to Lavinia than their Bolognese sisters had done; and Paul V. was himself among her sitters. Some of her portraits, often lavishly paid for, have been attributed to Guido. In works of a different kind also she united care and delicacy with boldness. Among the chief of these are a Venus in the Berlin Museum; the Virgin lifting a veil from the sleeping infant Christ, in the Escorial; and the Queen of Sheba visiting Solomon. Her own portrait in youth—she was accounted very beautiful—was perhaps her masterpiece; it belongs to the Counts Zappi of Imola, the family into which Lavinia married. She is deemed on the whole a better painter than her father; from him naturally came her first instruction, but she gradually adopted the Caraccesque style, with strong quasi-Venetian coloring. She was elected into the Academy of Rome, and died in that city in 1614.

FONTANA, Prospero (1512–1597), a painter, was born in Bologna, and became a pupil of Innocenzo da Imola. He afterwards worked for Vasari and Pierino del Vaga. It was probably from Vasari that Fontana acquired a practice of offhand, self-displaying work. He undertook a multitude of commissions, and was so rapid that he painted, it is said, in a few weeks an entire hall in the Vitelli Palace at Città di Castello. Along with daring, he had fertility of combination, and in works of parade he attained a certain measure of success, although his drawing was incorrect, and his mannerism palpable. He belongs to the degenerate period of the Bolognese school, under the influence chiefly of the imitators of Raphael—Sabbatini, Sammachini, and Passerotti being three of his principal colleagues. His soundest successes were in portraiture, in which branch of art he stood so high that towards 1550 Michelangelo introduced him to Pope Julius III. as a portrait-painter; and he was pensioned by this pope, and remained at the pontifical court with the three successors of Julius. Here he lived on a grand scale, and figured as a sort of arbiter and oracle among his professional brethren. Returning to Bologna, he opened a school of art, in which he became the preceptor of Lodovico and Agostino Caracci; but these pupils, standing forth as reformers and innovators, finally extinguished the academy and the vogue of Fontana. His subjects were in the way of sacred and profane history and of fable. He has left a large quantity of work in Bologna,—the picture of the Adoration of the Magi, in the Church of S. Maria delle Grazie, being considered his masterpiece—not unlike the style of Paul Veronese. His death took place in Rome in 1597.

FONTANES, Louis, Marquis de (1757–1821), French poet and politician, was born at Niort, in Poitou, March 6, 1757. He was a descendant of a noble Protestant family of Languedoc, banished by the revocation of the edict of Nantes, but afterwards converted to the Catholic faith and restored to their native land. Having completed his education at the college of Niort, he went in 1777, after the death of his father and brother, to Paris. He had already made several attempts in verse; and in 1778 he published a short descriptive poem entitled *La Forêt de Navarre.* This procured him the notice and friendship of Ducis, and he was encouraged to persevere. During the next twelve years he published *Le Cri de mon Cœur: Le Jour des Morts dans une Campagne*, an imitation of Gray's *Elegy;* a translation of Pope's *Essay on Man* (1783), with an elegant introduction which attracted more attention than the poem itself; *Le Verger; La Chartreuse de Paris;* and *L'Essai sur l'Astronomie* (1789). In this year appeared also his *Épître sur l'Édit en Faveur des non-Catholiques*, which was crowned by the Academy. The Revolution converted the poet into a journalist, and he took part in the editorship of the *Mercure François* and the *Moderateur.* Compelled to leave Paris after the death of the king, he withdrew to Lyons, where he married and remained till the arrival of Collot d'Herbois in 1793. Driven again to lead a wandering life, he displayed at once his literary power, his patriotism, and his intrepidity in the eloquent petition on behalf of the Lyonnese victims of Collot d'Herbois and his colleagues, which was presented to the Convention in December of that year. For this bold appeal he was proscribed, and he owed his protection in concealment to the friendship of Madame Dufresnoy. After the fall of Robespierre, Fontanes was appointed professor of belles lettres at the central school, and admitted a member of the Institute. About the same time he was associated with La Harpe in the conduct of the *Mémorial.* For one of his articles he was condemned to banishment by the Directory and expelled from the Institute. He escaped to England, and there renewed his acquaintance with Chateaubriand, also an exile. Returning to France after the 18th Brumaire, he was soon after commissioned by the first consul to write the funeral oration on Washington, and this opened a new chapter in his life. Bonaparte, satisfied with the *Éloge*, admitted Fontanes to frequent intercourse with him;

he was soon reinstated at the Institute, and became a member of the legislative body, of which in 1804 he was made president. He was also one of the first members of the Legion of Honor; and in 1808 he was made grand master of the university. Fontanes was censured by the republican party for alleged servility to the emperor; but apparently without reason. He was created count, and in 1810 was called to the senate. He voted for the deposition of Napoleon, retained his offices under the provisional government, and was made a peer by Louis XVIII. In February, 1815, the post of grand master of the university was suppressed, and Fontanes was promoted grand cordon of the Legion of Honor. He remained passive during the Hundred Days, and after the second restoration of the Bourbons was made a privy councillor. The title of marquis was conferred on him in 1817. In January, 1821, he was chosen president of the Société des Bonnes Lettres; but his health had long been declining, and he died at Paris on the 17th of March of that year. He left unfinished a poem entitled *La Grèce Delivrée*, of which high expectations had been formed. A collected edition of the works of Fontanes was first published by Sainte-Beuve, with a critical and biographical memoir, in 1837.

FONTARABIA. See FUENTERRABIA.

FONTENAY-LE-COMTE, the chief town of an arrondissement in the department of Vendée, France, is situated on both sides of the river Vendée at the point where it becomes navigable, 35 miles S.E. of La Roche-sur-Yon (Napoléon Vendée). The town has an antique and straggling appearance, but there are some good houses in the suburbs. It possesses a communal college, a prison, a hospital, a theatre, the remains of an old castle which formerly belonged to the counts of Poitiers, and two old and beautiful churches, Notre Dame and St. John. Both are of Romanesque architecture, terminated with Gothic spires, the spire of Notre Dame being 311 feet in height. The principal industries are the manufacture of coarse linen and woollen cloths, brewing and tanning; and there is a considerable trade in wine, fruits, timber, hemp, flax, and cattle.

Fontenay occupies the site of an old Roman town. It was captured by the English in 1361, and during the wars of the Huguenots it was ten times besieged. Louis XIII. in 1621 ordered the demolition of its fortifications, and in 1649 during the rebellion against the parliament, it fell into the hands of the nobles of Poitou. In the time of the Revolution it was called Fontenay-le-Peuple. Population in 1876, 7309.

FONTENELLE, BERNARD LE BOVIER DE (1657–1757), author of the *Dialogues des Morts*, *Entretiens sur la Pluralité des Mondes*, etc., was born at Rouen on the 11th of February, 1657, and died at Paris on the 9th of January, 1757, having thus very nearly attained the age of 100 years. His father was an advocate settled in Rouen, his mother a sister of the great Corneille. He was educated at the college of the Jesuits in his native city, and distinguished himself by the extraordinary precocity, as well as the amazing versatility, of his talents. His teachers, who readily appreciated these, were anxious to allure him into their order, but his father had designed him for the bar, and an advocate accordingly he became; but, having lost the first cause which was entrusted to him, he soon abandoned law in disgust and gave himself wholly to literary pursuits. His attention was first directed to poetical composition; and more than once he competed for the poetry prizes of the French Academy, but never with success. He had also the sorrow of witnessing, in 1680, the total failure of his tragedy *Aspar*, a failure which was all the more mortifying because, for the purpose of annoying Racine, Thomas Corneille had previously sounded forth in the *Mercure* the praises of his nephew as the most gifted of all the younger dramatists. Fontenelle afterwards acknowledged the justice of the public verdict by burning his unfortunate drama, of which nothing but the name now survives. But for several years he persisted in the belief that poetry was his true vocation, and continued to produce dramatic compositions, the mediocrity of which, considering the author's real talent, is positively astonishing. His opera of *Thétis et Pélée*, though highly praised by Voltaire, cannot be said to rise much above the others; and it is significant that of all his dramatic works, not one has kept the stage. His *Poésies Pastorales* have no greater claim to permanent repute, being characterized by stiffness and affectation; and the utmost that can be said for his poetry in general is that it displays much of the *limæ labor*, great purity of diction, and occasional felicity of expression. It was by his *Dialogues des Morts*, published in 1683, that Fontenelle first established a genuine claim to high literary rank; and that claim was very much enhanced three years later by the appearance of the *Entretiens sur la Pluralité des Mondes*, a work which was among the very first to illustrate the possibility of being scientific without being either uninteresting or unintelligible to the ordinary reader. It was precisely the kind of work which Fontenelle was capable of executing well, both from the natural bent of his intellect and from the course of his previous studies. His object was to popularize among his countrymen the astronomical theories of Descartes; and it may well be doubted if that philosopher ever ranked a more ingenious or successful expounder among the number of his disciples. Hitherto Fontenelle had continued to reside in Rouen, but in 1687 he removed to Paris for permanent residence there; and in the same year he published his *Histoire des Oracles*, a book which made a considerable noise in the theological as well as in the philosophical world. It was not so much an original work as a reduction from the Latin of Van Dale, and consisted of two essays, the first of which was designed to prove that oracles were not given by the supernatural agency of demons, and the second, that they did not cease with the birth of Christ. The clearness and precision of the style, and the smooth flow of the reasoning in this treatise, have been always much admired. It excited the suspicion of the church, however, and a Jesuit, by name Baltus, published a ponderous refutation of it; but the peace-loving disposition of its author impelled him to leave his opponent unanswered. He was too busy, he wrote to Leclerc, and added, "Enfin, je n'ai point du tout l'humeur polémique, et toutes les querelles me déplaisent. J'aime mieux que le diable ait été prophète, puisque le père jésuite le veut, et qu'il croit cela plus orthodoxe." To the following year (1688) belongs his *Digression sur les Anciens et les Modernes*, in which he took the modern side in a somewhat unnecessary controversy then raging; his *Doutes sur le Système Physique des Causes Occasionelles* (against Malebranche) appeared shortly afterwards. In 1691 he was received into the French Academy in spite of the determined efforts of Racine and Boileau, who on four previous occasions had secured his rejection. He subsequently was admitted a member both of the Academy of Inscriptions and of the Academy of Sciences; and in 1699 he became perpetual secretary to the latter body. This office he actually held for the long period of forty-two years; and it was in this official capacity that he wrote the *Histoire de l'Académie des Sciences*, containing extracts and analyses of the proceedings, and also the *Éloges* of the members. These last are written with great simplicity and delicacy; while of the prefaces to the *Histoire*, Saint-Beuve declares that in them "il à atteint à une véritable perfection, encore agréable et presque sévère." The only other works of Fontenelle that require to be mentioned are his *Géométrie de l'Infini* and his *Apologie des Tourbillons*. Of the former, his Academy composition, he himself is reported to have said (so far justly) —"There, now, is a book which only eight men in Europe can understand, and the author is not one of the eight." Fontenelle forms a link of connection between two very widely different periods of French literature, that of Corneille, Racine, and Boileau on the one hand, and that of Voltaire, D'Alembert, and Diderot on the other. It is not in virtue of his great age alone that this can be said of him; he actually had much in common with the *beaux esprits* of the 17th century, as well as with the *philosophes* of the 18th. But it is to the latter rather than to the former period that he properly belongs; and it is not a little significant that while as a poet and man of fashion he was "the butt of all the clever men in Paris" during the first fifty years of his life, he latterly came to be "a force and an authority in the intellectual life" of the period. He has no claim to be regarded as a genius; but, as Sainte-Beuve has said, he well deserves a place "dans la classe des esprit infiniments distingués"—distinguished, however, it ought to be added by intelligence rather than by intellect, and less by the power of saying much than by the power of saying a little well. In personal character he has sometimes been described as having been revoltingly heartless; and it is abundantly plain that he was singularly incapable of feeling strongly the more generous emotions—a misfortune, or a fault, which revealed itself in many ways. "Il faut avoir de l'âme pour avoir du gout." But the cynical expressions of such a man are not to be taken too literally; and the mere fact that he lived and died in the esteem of many friends suffices to show that the theoretical selfishness which he sometimes professed cannot have been consistently and at all times carried into practice.

There have been several collective editions of Fontenelle's works. The best are those of Paris, in 8 vols. 8vo, 1790, and 5 vols. 8vo, 1825. Some of his separate works have been very frequently reprinted and also translated. The *Pluralité des Mondes* was translated into modern Greek in 1794. Sainte-Beuve has an interesting essay on Fontenelle, with several useful references, in the *Causeries du Lundi*, vol. iii.

FONTEVRAULT, or FONTEVRAUD, in Latin *Fons Ebraldi*, a town of France, with a population of about 2500, in the department of Maine-et-Loire, 10 miles S.E. of Saumur, and 2 miles from the confluence of the Loire and Vienne. It is situated in the midst of a forest district, and the inhabitants carry on various minor industries fostered by the timber trade. The interest of the place centres in its abbey, which since 1804 has been utilized and abused as a central house of detention for convicts. In spite of mutilation and "translation" the building remains a fine example of the architecture of the 12th century. The church, of which only the choir and apse are appropriated to divine service, has a beautiful nave covered by four cupolas. In a chapel in the south transept are the effigies of Henry II. of England and his wife Eleonora of Guienne, and of Richard the Lion Heart and his wife Isabella of Angoulême—Eleanora's being of oak and the rest of stone. The second court of the abbey contains a remarkable building, which long went under the misnomer of *chapelle funéraire*, but was in reality the old kitchen. Details and diagrams will be found in Viollet-le-Duc's *Dictionnaire de l'Architecture*. There are three stories, of which the first is an octagon, the second a square, and the third an octagon; and the whole is surmounted by a sort of pyramidal structure. Fontevrault was founded about the end of the 11th century by Robert of Arbrissel, who was born in the village of Arbrissel or Arbresec, in the diocese of Rennes, and attained great fame as a preacher and ascetic. It consisted of a nunnery for virgins and widows, a magdaleneum, a hospital for lepers and other diseased folk, a convent, and a church. The church was used both by the monks and the nuns, but no communication was permitted between the two sexes. The order of Fontevrault was recognized by Pascal II. in 1106, and again more expressly by a bull in 1113. It was placed by its founder under the patronage of the Holy Virgin, and entrusted to the superintendence of an abbess, who was supreme not only over the nuns but also over the monks. The first who held the office was Petronella de Craon-Chemillé. The success of the order was so great that at Robert's death it is said there were no fewer than 3000 nuns. It ultimately numbered fifty-seven priories, divided into the four provinces of France, Aquitaine, Auvergne, and Brittany. It continued till the French Revolution, and the abbey of Fontevraud was the usual place to which the princesses of the blood royal of France were sent for their education. The last abbess, Julie Sophie Charlotte de Pardaillan, died at Paris in 1799 in great destitution.

See Édouard, *Fontevrault et ses monuments, ou Histoire de cette royale abbaye depuis sa fondation jusqu' à sa suppression (1100–1793), ornée d'une gravure et des armoiries des abbesses*, 2 vols., 1875.

FOOD. See DIETETICS.

FOOL. The class of fools, buffoons, or jesters, which reached its culminating point of influence and recognized place and function in the social organism during the Middle Ages, appears to have existed in all times and countries. Not only have there always been individuals naturally inclined and endowed to amuse others; there has been besides in most communities a definite class, the members of which have used their powers or weaknesses in this direction as a regular means of getting a livelihood. Savage jugglers, medicine-men, and even priests, have certainly much in common with the jester by profession. There existed in ancient Greece a distinct class of professed fools whose habits were not essentially different from those of the jesters of the Middle Ages. Of the behavior of one of these, named Philip, Xenophon has given a picturesque account in the *Banquet*. Philip of Macedon is said to have possessed a court fool, and certainly these (as well as court poets and court philosophers, with whom they have sometimes been not unreasonably confounded) were common in a number of the petty courts at that era of civilization. *Scurræ* and *moriones* were the Roman parallels of the mediæval witty fool; and during the empire the manufacture of human monstrosities was a regular practice, slaves of this kind being much in request to relieve the languid hours. The jester again has from time immemorial existed at eastern courts. Witty stories are told of Bahalul (see D'Herbelot, *s.v.*) the jester of Haroun Al Raschid, which have long had a place in Western fiction. On the conquest of Mexico court fools and deformed human creatures of all kinds were found at the court of Montezuma. But that monarch no doubt hit upon one great cause of the favor of monarchs for this class when he said that "more instruction was to be gathered from them than from wiser men, for they dared to tell the truth." Mr. Douce, in his essay *On the Clowns and Fools of Shakespeare*, has made a ninefold division of English fools, according to quality and place of employment, as the domestic fool, the city or corporation fool, the tavern fool, the fool of the mysteries and moralities. The last is generally called the "vice," and is the original of the stage clowns so common among the dramatists of the time of Elizabeth, and who embody so much of the wit of Shakespeare. A very palpable classification is that which distinguishes between such creatures as were chosen to excite to laughter from some deformity of mind or body, and such as were so chosen for a certain (to all appearance generally very shallow) alertness of mind and power of repartee,—or briefly, butts and wits. The dress of the regular court fool of the Middle Ages was not altogether a rigid uniform. To judge from the prints and illuminations which are the sources of our knowledge on this matter, it seems to have changed considerably from time to time. The head was shaved, the coat was motley, and the breeches tight, with generally one leg different in color from the other. The head was covered with a garment resembling a monk's cowl, which fell over the breast and shoulders, and often bore asses' ears, and was crested with a cockscomb, while bells hung from various parts of the attire. The fool's bauble was a short staff bearing a ridiculous head, to which was sometimes attached an inflated bladder, by means of which sham castigations were effected. A long petticoat was also occasionally worn, but seems to have belonged rather to the idiots than to the wits.

The fool's business was to amuse his master, to excite him to laughter by sharp contrast, to prevent the over-oppression of state affairs, and, in harmony with a well-known physiological precept, by his liveliness at meals to assist his lord's digestion. The names and the witticisms of many of the official jesters at the courts of Europe have been preserved by popular or state records. In England the list is long between Hitard, the fool of Edmund Ironside, and Muckle John, the fool of Charles I., and probably the last official royal fool of England. Many are remembered from some connection with general or literary history. Scogan was attached to Edward IV., and under his name Andrew Boorde published a collection of poor jests. Will Sommers, of the time of Henry VIII., seems to have been a kind-hearted as well as a witty man, and occasionally used his influence with the king for good and charitable purposes. Arnim, who, in his *Nest of Ninnies*, gives a full description of Sommers, and introduces many popular fools, says of him—

> "Only this much, he was a poor man's friend,
> And helpt the widow often in her end.
> The king would ever grant what he would crave,
> For well he knew Will no exacting knave."

The literature of the period immediately succeeding his death is full of allusions to Will Sommers. John Heywood was an educated man, a poet and dramatist, as well as jester to Queen Mary. Some of his dialogues have in conception a racy national humor. John Tarleton, famous as a comic actor, cannot be omitted from any list of jesters. A book of Tarleton's *Jests* was published in 1611, and, together with his *News Out of Purgatory*, was reprinted by Mr. Halliwell for the Shakespeare Society in 1844. Archie Armstrong, for a too free use of wit and tongue against Laud, lost his office and was banished the court. The conduct of the archbishop against the poor fool is not the least item of the evidence which convicts him of a certain narrow-mindedness and pettiness. In French history, too, the figure of the court-jester flits across the gay or sombre scene at times with fantastic effect. Caillette and Triboulet are well-known characters of the times of Francis I. Triboulet appears in Rabelais's romance, and is the hero of Victor Hugo's *Le Roi s'amuse*, and, with some changes, of Verdi's opera *Rigoletto;* while Chicot, the lithe and acute Gascon, who was so close a friend of Henry III., is portrayed with considerable justness by Dumas in his *Dame de Monsoreau.* In Germany Rudolph of Hapsburg had his Pfaff Cappadox, Maximilian I. his Kunz von der Rosen (whose features, as well as those of our own Will Sommers, have been preserved by the pencil of Holbein), and many a petty court its jester after jester. Late in the 16th century appeared *Le Sottilissime Astuzie di Bertoldo,* which is one of the most remarkable books ever written about a jester. It is by Giulio Cesare Croce, a street musician of Bologna, and is a comic romance giving an account of the appearance at the court of Alboin king of the Lombards of a peasant wonderful in ugliness, good sense, and wit. The book was for a time the most popular in Italy. A great number of editions and translations appeared, and it was even versified. Though fiction, both the character and the career of Bertoldo are typical of the jester. That the private fool existed as late as the last century is proved by Swift's epitaph on Dicky Pearce, the earl of Suffolk's jester.

FOOTBALL is a game which consists, as the name implies, in giving motion to a ball with the feet alone. It has been aptly designated the "winter game" of Great Britain, and justly takes the place of cricket from Michaelmas to Lady Day. The ball requires to be larger than in all handball pastimes, in order that it may be easily kicked. This was accomplished in ancient times by inflating a bladder or skin termed *follis.* In Greece the ἐπίσκυρος seems to have borne a resemblance to the modern game. Of this we read in Smith's *Dictionary of Antiquities*—"It was the game at football, played in much the same way as with us, by a great number of persons divided into two parties opposed to one another." Amongst the Romans the *harpastum,* derived from the Greek verb ἁρπάζω, to seize, thus showing that carrying the ball was permissible, bore a certain resemblance. Basil Kennett, in his *Romæ Antiquæ Notitia,* terms this missile a "larger kind of ball, which they played with, dividing into two companies and striving to throw it into one another's goals, which was the conquering cast,"—a description which, if correct, certainly bears a strong resemblance to the modern game of football. The antiquity of football in Great Britain (introduced, there can be little doubt, by the Romans) goes some centuries farther back than cricket, probably because the requisites—only an inflated ball and rude goals—were fewer and simpler than in the summer game. The birthplace of the latter was in the southern counties, that of football in the north. In early times the great football festival of the year was Shrove Tuesday, though the connection of the game with this particular date is lost in obscurity. William Fitzstephen, in his *History of London* (about 1175), speaks of the young men of the city annually going into the fields after dinner to play at the well-known game of ball on the day *quæ dicitur Carnilevaria.* As far as is known this is the first distinct mention of football in England. A clear reference is made "ad pilam . . . pedinam" in the Rotuli Clausarum, 39 Edward III. (1365), memb. 23, as one of the pastimes to be prohibited on account of the decadence of archery, and the same thing occurs in 12 Richard II. c. 6 (1388). Down to the end of the first quarter of the present century Shrove Tuesday continued to be the high festival of football, but it had never taken root, like cricket, amongst the aristocracy and gentry. It was confined to the middle and lower classes. No clubs or code of rules had been formed, and the sole aim seems to have been to drive the ball through the opposing side's goal by fair means or foul. So rough did the game become that James I. forbade the heir apparent to play it, and describes the exercise in his *Basilikon Doron* as "meeter for laming than making able the users thereof." Both sexes and all ages seem to have taken part in it on Shrove Tuesday; shutters had to be put up and houses closed in order to prevent damage; and it is not to be wondered that the game fell into bad repute under such violent horse-play and eccentric usages. Accidents, sometimes fatal, occurred; and Shrove Tuesday "football-day" gradually died out about 1830. For some thirty years football was only practised at the great public schools, at which there were, as still, two distinct forms of play. The Rugby game, so aptly described in *Tom Brown's School Days,* resembles the Roman *harpastum* and the rough Shrove-tide play, since seizing and carrying the ball, charging, and one player's holding another are freely allowed, and actual hacking was abolished at Rugby only as lately as 1877. Harrow and Winchester are the chief exponents of the game wherein kicking alone is allowed as a means of propulsion. Eton plays a hybrid game in two different ways, viz., "At the Wall" and "In the Field," the latter being a sort of mixture of both kinds of play. All other schools have arrayed themselves under one or other of these banners, with slight modifications in their rules. About the year 1860, when the great volunteer movement and the institution of amateur athletic sports gave a zest to many kinds of exercises, there came a revival of football amongst old public school and university men. It was soon found that a universal code of rules and a society to legislate on matters of dispute were necessary. Followers of the strict foot game were the first to recognize these wants, and the "Football Association" was accordingly formed in 1863, the exponents of the other method not banding themselves together till the "Rugby Football Union" was instituted in 1871.

Football has extended most rapidly throughout the United Kingdom during the past few years, as is evinced by the fact of all large towns, villages, and schools now possessing football clubs, and has regularly taken the place of cricket during the winter months. It is a game more adapted to youths than to middle-aged persons, and should not be indulged in after the frame is full-grown and set, when the tumbles and scrimmages incidental to the Rugby code are apt to be baneful. The balls are now made of inflated india-rubber bladders, covered with strong leather laced together, the Rugby balls being elliptical or egg-shaped, and the association ones a perfect sphere.

The two games may be briefly described thus:—

Under the Rugby code a level piece of turf is the scene of action, and fifteen a side the usual number of players—ten "forwards," two "half backs," one "three-quarters back," and two "backs." Each goal is composed of two upright posts, exceeding 11 feet in height, and placed 18½ feet apart, with a cross-bar 10 feet clear from the ground. The choice of goals is decided by lot, the side which wins the choice either availing themselves of any favorable breeze or gradients which may prevail, or electing to play at a disadvantage for the first period of the game till "half time" is called. The game is commenced by the opposite side to that which has choice of goals kicking off the ball (placed on the ground) from midway between the two goals. The object of both sides then is to drive the ball over the cross-bar, and between the line of the two upright posts of their opponents' goal, which achievement constitutes "obtaining a goal." This can be accomplished either by a player's touching the ball down behind his adversaries' goal line, then carrying it out, and thus obtaining a "try" or place kick at goal, or by kicking at goal with a direct drop-kick instantly the ball rebounds from the ground. A match is decided by a majority of goals; if their number be equal, by a majority of ties; and if none of either be obtained, the match is drawn. The other minutiæ are so numerous that no less than sixty rules are required for their regulation.

The intricacies of the Association game are far fewer, and only require a very plain set of thirteen rules. No handling or touching the ball, except by the goal-keeper, is permissible, "dribbling" or kicking with the feet being the sole mode of propulsion. The goal posts are 24 feet apart, and the cross-bar only 8 feet from the ground, the ball in this case having to be driven *under* the latter in order to obtain a goal. "Tries" are unknown, and the gaining of goals is the sole point whereby the game is decided.

The rules of both games will be found in most football works, the chief of which are Routledge's *Handbook of Football,* 1867; C. W. Alcock's *Football Annual,* annually from 1868; Alcock's *Football, our Winter Game,* 1874; G. H. West's *Football Calendar,* annually from 1874. (H. F. W.)

FOOTE, SAMUEL (*c.* 1720–1777), comic dramatist and actor, was born at Truro about the year 1720. Of his attachment to his native Cornwall he gives no better proofs as an author than by making the country-booby Timothy (in *The Knights*) sound the praises of that county and of its manly pastimes; but towards his family he showed a loyal and enduring affection. His father was a man of good family and position; his mother, the daughter of a baronet (Sir Edward Goodere), is said, in person as well as in disposition, to have strongly resembled her famous son. According to tradition, she afterwards fell into pecuniary embarrassments closely analogous to his own; but in the days of his prosperity he liberally supported both her and an unfortunate clerical brother. After her death he indignantly vindicated her character from the imputations recklessly cast upon it by the revengeful spite of the duchess of Kingston. About the time when Foote came of age, a family quarrel between his two maternal uncles ended in the brutal murder, under extraordinary circumstances, of the one by the other, who was, with his accomplices, hanged for the crime. By this event Foote came into his first fortune, through which he ran with great speed in the beginning of his London life. Before this he had completed his education in the collegiate school at Worcester, and at Worcester College, Oxford, distinguishing himself in both places by practical jokes, mimicry, and audacious pleasantries of all kinds, but also acquiring a classical training which afterwards enabled him neatly to turn a classical quotation or allusion, and helped to give to his prose style, when he chose to write seriously, a sufficient degree of fluency and elegance.

Foote was, it is stated, "designed" for the law, but certainly not by nature. In his chambers at the Temple, and in the Grecian Coffee-house hard by, he learned to know something of lawyers if not of law, and picked up a smattering of law-terms, and a knowledge of the forms and features of ordinary law-suits. Thus he was afterwards able to jest at the jargon and to mimic the mannerisms of the bar, and to satirize the Latitats of the other branch of the profession with particular success. The famous argument in Hobson *v.* Nobson (in *The Lame Lovers*) is as good of its kind as that in Bardell *v.* Pickwick itself; and doubtless Foote had duly studied some of the most ludicrous or contemptible types among the 1175 barristers ("if we reckon one barrister to twenty attorneys") and 23,518 attorneys (if we "only quarter one attorney upon fifty houses"), of whom, according to the lecturer in *The Orators*, the profession was in his day composed. But a stronger attraction drew him to the Bedford Coffee-house in Covent Garden, and to the theatrical world of which it was the social centre. After he had got rid of a second fortune (which he appears to have inherited at his father's death), and had in the interval passed through severe straits of want, he gave up playing the part of a fine gentleman, and in 1744 made his first appearance on the actual stage. Whether before this time Foote had married remains a very doubtful question. It is said that about the time of the family catastrophe he had married a young lady in Worcestershire—actually, and not in imagination only, like young Wilding in *The Liar;* but the traces of his wife (he affirmed himself that he was married to his "washerwoman") are mysterious, and probably apocryphal; in after days no lady presided at his table, or controlled the libations of claret which flowed with equal abundance in his servants' hall, and his two sons were illegitimate.

Foote's first appearance as an actor was made little more than two years after that of Garrick, as to whose merits the critics, including Foote himself, were now fiercely at war. His own first venture, as Othello, was a failure; and though he was fairly successful in genteel comedy parts, and was, after a favorable reception at Dublin, enrolled as one of the regular company at Drury Lane in the winter of 1745–46, he had not as yet made any palpable hit. Finding that his talent lay neither in tragedy nor in genteel comedy, he had begun to wonder (as he tersely expressed it) "where the devil it *did* lie," when his successful performance of the part of Bayes in *The Rehearsal* at last suggested to him the true outlet for his peculiar talent. Following the example of Garrick, he had introduced into this famous part imitations of actors, and had added a variety of other satirical comment in the way of what in stage parlance is called "gag." He lost no time in availing himself of the discovery that in his powers of mimicry lay his surest means of securing a hold over the public. After engaging a small company of actors, he boldly announced for April 22, 1747, at the theatre in the Haymarket ("*gratis*"), "a new entertainment called the *Diversions of the Morning*," to which were to be added a farce adapted from Congreve, and an epilogue "spoken by the B—d—d Coffee-house." Though, of course, nine-tenths of the fun in all such entertainments would evaporate even in a shorthand report, and though of these *Diversions* it is only possible to form a notion from scattered recollections and from such parts as were afterwards incorporated in one of Foote's comedies (*Taste*, act i.), or adapted for later reproduction at Drury Lane (act ii., printed in Cooke' *Memoirs*), yet there is no difficulty in understanding the secret of Foote's immediate success, which is said at once to have obtained for him the name of "the English Aristophanes." The absurdity of this compliment has often been remarked upon; but it may be worth observing that Foote was probably himself the first (in his letter on *The Minor*) to decline the comparison, while "leaving the task of pointing out the mistake to his enemies." The *Diversions* consisted of a series of imitations of actors and other well-known persons, whose various peculiarities of voice, gesture, manner or dress were brought directly before the spectators; while the epilogue introduced the wits of the Bedford engaged in ludicrous disputation, and specially "took off" an eminent physician and a notorious quack oculist of the day. The actors ridiculed in this entertainment having at once procured the aid of the constables for preventing its repetition, Foote immediately advertised an invitation to his friends to drink a dish of tea with him at the Haymarket on the following day at noon—"and 'tis hoped there will be a great deal of comedy and some joyous spirits; he will endeavor to make the morning as diverting as possible. Tickets for this entertainment to be had at St. George's Coffee-house, Temple-Bar, without which no person will be admitted. N. B.—*Sir Dilbury Diddle will be there, and Lady Betty Frisk has absolutely promised.*" The device succeeded to perfection; further resistance was abandoned as futile by the actors, whom Foote mercilessly ridiculed in the "instructions to his pupils" which the entertainer pretended to impart (typifying them under characters embodying their several chief peculiarities or defects—the massive and sonorous Quin as a watchman, the shrill-voiced Ryan as a razor-grinder, the charming Woffington, whose tones had an occasional squeak in them, as an orange-woman crying her wares and the bill of the play); and Mr. Foote's *Chocolate*, which was afterwards converted into an evening *Tea*, became an established favorite with the town.

The way to fame and its fruits having now at last been found, the remainder of Foote's professional career was on the whole prosperous enough. He seems, indeed, after this to have contrived to spend a third fortune, and to have found it necessary to eke out his means by a speculation in small-beer, as is recorded in an amusing anecdote told of him by Johnson. But whatever abstract arguments he might find in favor of the life of a man in debt and against the practice of "muddling away money in tradesmen's bills," he could now command a considerable income; and when money came he seems (like a true actor) to have freely divided it between the pleasures of hospitality and the claims of charity. During his engagements at Covent Garden and at Drury Lane (of which he was, in passing, joint-manager), and in professional trips to Scotland, and more especially to Ireland, he appeared both in comedies of other authors and more especially in his own. Among the latter, of which something will be said below, *Taste* (1752) is the first of a series numbering (exclusively of the *Diversions* and one or two similar pieces) eighteen. The majority of them were produced at the Haymarket, which continued the favorite home of Foote's entertainments, and for which in 1760 he succeeded in obtaining a license from the lord chamberlain, afterwards (in 1766) converted into a license for summer performances for life. The entertainments in question may be briefly described as a succession of variations on the original idea of the *Diversions* and the *Tea*. Now, it was an *Auction of Pictures* (1748), of part of which an idea may be formed from the second act of the comedy *Taste;* now, a lecture on *Orators* (1754), suggested by some bombastic discourses given by Macklin in his old age at the Piazza Coffee-house in Covent Garden, where Foote had amused the audience and confounded the speaker by interposing his humorous comments. *The Orators* is preserved in the shape of a hybrid piece, which begins with a mock lecture on the art of oratory and its representatives in England, and ends with a very diverting scene of a pot-house forum debate, to which Holberg's *Politician-Tinman* can hardly have been a stranger. At a later date (1773) a new device was introduced in a *Puppet-*

show; and it is a pity that the piece played in this by the puppets should not have been committed to print. It was called *Piety in Pattens*, and professed to show "by the moral how maidens of low degree might become rich from the mere effects of morality and virtue, and by the literature how thoughts the most commonplace might be concealed under cover of words the most high flown." In other words, it was an attack upon sentimental comedy, to which more than one blow had been already dealt, but which was still not altogether extinguished. Indeed, though no one now reads *Pamela*, it may be doubted whether she and her cousinhood will ever be altogether suppressed on the modern stage. The *Puppet-show* was also to have contained a witty attack upon Garrick in connection with the notorious Shakespeare jubilee; but this was withdrawn, and thus was avoided a recurrence of the quarrel which many years before had led to an interchange of epistolary thrusts, when the manager of Drury Lane had permitted Woodward to attempt an imitation of Foote. On the whole, the relations between the two public favorites were very friendly, and on Foote's part (notwithstanding a number of witticisms directed especially against Garrick's interest in Queen Anne's farthings and the like) unmistakably affectionate; and they have been by no means fairly, or at least generously, represented by Garrick's most recent biographer. A comparison between the two as actors is of course out of the question; but, though Foote was a buffoon, and his tongue a scurrilous tongue, there is nothing in the well-authenticated records of his life to suggest that his character was one of malicious heartlessness. On the other hand, it was not altogether the fault of his position that he was unable to conciliate the respect of society, though, unlike Garrick, he could hardly have expected to form one of the chosen circle into which (though not without protest) the former gained admittance. It is at the same time characteristic of the difference between the London of that day and the London of our own, where club secrets are among the favorite morsels of public gossip, that the famous Club had been ten years in existence before Foote knew of it. Of Johnson's opinions of him many well-known records remain in Boswell; and if it is remembered that when Johnson had at last found his way into Foote's company (he afterwards found it to Foote's own table) he was unable to "resist" him, it should likewise not be forgotten that on hearing of Foote's death he recognized his career as worthy of a lasting biographical record.

Meanwhile most of poor Foote's friendships in high life were probably those that are sworn across the table, and require "t'other bottle" to keep them up. It is not a pleasant picture—of Lord Mexborough and his royal guest the duke of York, and their companions, bantering Foote on his ignorance of horsemanship, and after he had weakly protested his skill, taking him out to hounds on a dangerous animal. He was thrown and broke his leg, which had to be amputated, the "patientee" (in which character he said he was now making his first appearance) consoling himself with the reflection that he would now be able to take off "old Faulkner" (a pompous Dublin alderman with a wooden leg, whom he had brought on the stage as Peter Paragraph in *The Orators*) "to the life." The duke of York made him the best reparation in his power by promising him a life-patent for the theatre in the Haymarket (1766); and Foote not only resumed his profession, as if, like Sir Luke Limp, he considered the leg he had lost "a redundancy, a mere nothing at all," but ingeniously turned his misfortune to account in two of his later pieces, *The Lame Lover* and *The Devil on Two Sticks*, while, with the true instinct of a public favorite, making constant reference to it in plays and prologues. He seemed to have lost none of his energy with his leg, though it may be observed that the characters played by him in several of his later plays are comparatively short and light. He continued to retain his hold over the public, and about the year 1774 was beginning to think of withdrawing, at least for a time, to the Continent, when he became involved in what proved a fatal personal quarrel. Neither in his entertainments nor in his comedies had he hitherto (except in Garrick's case, and it is said in Johnson's) put the slightest restraint upon the personal satire by which he terrified his victims and delighted their neighbors. One of his earlier experiments of this kind (*The Author*), in which, under the infinitely humorous character of Cadwallader, he had brought a Welsh gentleman of the name of Ap-Rice on the stage, had, indeed, ultimately led to the suppression of the play. But, to an extent of which it is impossible fully to judge, he had pursued his hazardous course, mercilessly exposing to public ridicule and contempt not only fribbles and pedants, quacks or supposed quacks in medicine (as in *The Devil on Two Sticks*), impostors or supposed impostors in religion, such as Dr. Dodd (in *The Cozeners*) and Whitfield and his connection (in *The Minor*). He had not only dared the wrath of the whole Society of Antiquaries (in *The Nabob*), and been rewarded by the withdrawal, from among the pundits who rationalized away Whittington's Cat, of Horace Walpole and other eminent members of the body, but had in the same play attacked a well-known representative of a very influential though detested element in English society,—the "Nabobs" themselves. But there was one species of cracked porcelain or blemished reputation which he was not to try to hold up to contempt with impunity. The rumor of his intention to bring upon the stage, in the character of Lady Kitty Crocodile in *The Trip to Calais*, the notorious duchess of Kingston, whose trial for bigamy was then (1775) impending, roused his intended victim to the utmost fury; and the means and influence she had at her disposal enabled her, not only to prevail upon the lord chamberlain to prohibit the performance of the piece (in which, it should be observed, there is no hint as to the charge of bigamy itself), but to hire agents to vilify Foote's character in every way that hatred and malice could suggest. After he had withdrawn the piece, and letters had been exchanged between the duchess and him equally characteristic of their respective writers, Foote took his revenge upon the chief of the duchess's instruments, a "Reverend Doctor" Jackson, who belonged to the "reptile" society of the journalists of the day, so admirably satirized by Foote in his comedy of *The Bankrupt*. This man he gibbeted in the character of Viper in *The Capuchin*, under which name the altered *Trip to Calais* was performed in 1776. But the resources of his enemies were not yet at an end; and a discharged servant of Foote's was suborned by Jackson to bring a charge and apply for a warrant against him. Though the attempt utterly broke down, and Foote's character was thus completely cleared, his health and spirits had given way in the struggle—as to which, though he seems to have had the firm support of the better part of the public, including such men as Burke and Reynolds, the very audiences of his own theatre had been, or had seemed to be, divided in opinion. He thus resolved to withdraw, at least for a time, from the effects of the storm, let his theatre to Colman, and after making his last appearance there in May, 1777, set forth in October on a journey to France. But at Dover he fell sick on the day after his arrival there, and after a few hours died (October 21st). His epitaph in St. Mary's Church at Dover (written by his faithful treasurer Jewel) records that he had a hand "open as day for melting charity." His resting-place in Westminster Abbey is without any memorial; nor indeed is it the actor's usual lot to receive from posterity any recognition which the contemporaries whom he has delighted have denied to him.

Foote's chief power as an actor must clearly have lain in his extraordinary gift of mimicry, which extended, as the best kind of mimicry always does, to the mental and moral, as well as the mere outward and physical peculiarities of the personages whose likeness he assumed. He must have possessed a wonderful flexibility of voice, though his tones are said to have been harsh when his voice was not disguised, and an incomparable readiness for rapidly assuming characters, both in his entertainments and in his comedies, where he occasionally "doubled" parts. The excellent "patter" of some of his plays, such as *The Liar* and *The Cozeners*, must have greatly depended for its effect upon rapidity of delivery. In person he seems to have been by nature ill-qualified for light comedy parts, being rather short and stout, and coarse featured; but the humor with which he overflowed is said to have found full expression in the irresistible sparkle of his eyes.

As a dramatic author, although he displays certain distinctive characteristics of indisputable brilliancy, he can only be assigned a subordinate rank. He was himself anxious to limit the definition of comedy to "an exact representation of the peculiar manners of that people among whom it happens to be performed; a faithful imitation of singular absurdities, particular follies, which are openly produced, as criminals are publicly punished, for the correction of individuals and as an example to the whole community." This he regarded as the *utile*, or useful purpose, of comedy; the *dulce* he conceived to be "the fable, the construction, machinery, conduct, plot, and incidents of the piece." For part at least of this view (advanced by him in the spirited and scholarly "Letter" in which he replied, "to the Reverend Author of the 'Remarks, Critical and Christian,' on *The Minor*") he rather loftily appealed to classical-authority. But he failed to point out the relation between the *utile* and the *dulce*, and to remember the indispensableness of the latter to the comic drama under its primary aspect as a species of art. His comic genius was particularly happy in discovering and reproducing characters deserving of ridicule; for "affectation," he says (in the introduction to *The Minor*, where he appears in person), "I take to be the true comic object;" but he failed in putting them to true artistic use. That he not only took his chief characters from real life, but closely modelled them on well-known living men and women, was not in himself an artistic sin, though it may have been a practice of doubtful social expediency, as it certainly involved considerable personal risk. Nor was the novelty of this absolute, but rather one of degree and quantity; other comic dramatists before and after him have done the same thing, though probably no other has ever gone so far in this course, or has pursued it so persistently. The public delighted in his "d——d fine originals," because it recognized them as copies; and he was himself proud that he had taken them from real persons, instead of their being "vamped from antiquated plays, pilfered from the French farces, or the baseless beings of the poet's brain." But the real excellence of Foote's comic characters lies in the fact that, besides being incomparably ludicrous types of manners, many of them remain admirable comic types of general human nature. Sir Gregory Gazette, and his imbecile appetite for news; Lady Pentweazel, and her preposterous vanity in her superannuated charms; Mr. Cadwallader, and his view of the advantages of public schools (where children may "make acquaintances that may hereafter be useful to them; for between you and I, as to what they learn there, does not signify twopence"); Major Sturgeon and Jerry Sneak; Sir Thomas Lofty, Sir Luke Limp, Mrs. Mechlin, and a score or two of other characters, are excellent comic figures in themselves, whatever their origin; and many of the vices and weaknesses exposed by Foote's vigorous satire will remain the perennial subjects of comic treatment so long as a stage exists. The real defect of his plays lies in the abnormal weakness of their construction, in the absolute contempt which the great majority of them show for the invention or conduct of a plot, and in the unwarrantable subordination of the interest of the action to the exhibition of particular characters. In a good play, whether it be tragedy or comedy, the characters are developed out of and by means of the action; but of this there is little trace in Foote. His characters are ready-made, and the action is only incidental to them. With the exception of *The Liar* (which Foote pretended to have taken from Lope de Vega, but which was really founded on Steele's adaptation of Corneille's *Le Menteur*), and perhaps of *The Bankrupt*, there is hardly one of Foote's "comedies" in which the conception and conduct of the action rise above the exigences of the merest farce. Not that sentimental scenes and even sentimental characters are wanting, that virtue is not occasionally in distress, or fails to vindicate itself triumphantly from the semblance of vice; but these familiar procedures are as incapable of exciting real interest as the ordinary course of a farcical action is in itself calculated to produce more than the most transitory amusement. In his earlier plays Foote constantly resorts to the most hackneyed device of farce—a disguise—which helps on the progress of a slender fable for which nobody cares to a close which everybody foresees. Of course Foote must have been well aware of the defect under which his rapidly manufactured productions labored; he knew that if he might sneer at "genteel comedy" as suited to the dramatists of the servants' hall, and pronounce the arts of the drama at the great houses to be "directed by the genius of insipidity," he, like the little theatre where he held sway, was looked upon as "an eccentric, a mere summer fly."

His merits as a comic dramatist are not, however, obscured by his incontestable defects. He was inexhaustible in the devising of comic scenes of genuine farce, in which the humor and wit of the dialogue are on a level with the general excellence of the conception. An oration of "old masters," an election of a suburban mayor, an examination at the College of Physicians, a newspaper conclave where paragraphs are concocted and reputations massacred—all these and other equally happy scenes are brought before the mere reader with unfailing vividness. And everywhere the comic dialogue is instinct with spirit and vigor, and the comic characters are true to themselves with a buoyancy which at once raises them above the level of mere theatrical conventionalism. Foote professed to despise the mere caricaturing of national peculiarities as such, and generally used dialect as a mere additional coloring; he was, however, too wide awake to the demands of his public not to treat France and Frenchmen as fair game, and perhaps there is nothing coarser in his plays than his constant appeal to national patriotic prejudice. His satire against those everlasting victims of English comedy and farce, the Englishman in Paris and the Englishman returned from Paris, was doubtless well warranted; and he was not slow to point out the fact—which Englishmen are wont to conceal when they come home from their travels—that they are nowhere more addicted to the society of their countrymen than abroad. In general, the purposes of Foote's social satire are excellent, and the abuses against which it is directed are those which it required courage to attack. The tone of his morality is healthy, and his language, though not aiming at refinement, is remarkably free from intentional grossness. Like all professed humorists, he made occasional mistakes; but he, too, was on the right side in the warfare against the pretentiousness of Cant and the effrontery of Vice, the two master evils of the age and the society in which he lived.

The following is a list of Foote's farces or "comedies," as he calls them, mostly in three, some in two acts, which remain in print. The date of production, and the character originally performed by Foote, are added to the title of each:—

The Knights (1748—Hartop, who assumes the character of Sir Penurious Trifle); *Taste* (1752); *The Englishman in Paris* (1753—Young Buck); *The Englishman Returned from Paris* (1756—Sir Charles Buck); *The Author* (1757—Cadwallader); *The Minor* (1760—Smirk and Mrs. Cole); *The Liar* (1760); *The Orators* (1762—Lecturer); *The Mayor of Garratt* (1763—Major Sturgeon); *The Patron* (1764—Sir Thomas Lofty and Sir Peter Peppercorn); *The Commissary* (1765—Mr. Zac. Fungus); *The Devil upon Two Sticks* (1768—Devil); *The Lame Lover* (1770—Sir Luke Limp); *The Maid of Bath* (1771—Mr. Flint); *The Nabob* (1772—Sir Matthew Mite); *The Bankrupt* (1773—Sir Robert Riscounter); *The Cozeners* (1774—Mr. Aircastle); *A Trip to Calais; The Capuchin* (1776—O'Donnovan).

Foote's biography may be read in W. ("Conversation") Cooke's *Memoirs of Samuel Foote* (3 vols., 1805), which contain a large collection of his good things and of anecdotes concerning him, besides two of his previously unpublished occasional pieces (with the act of the *Diversions* in a later form already mentioned), and an admixture of extraneous matter. From this source seems to have been mainly taken the biographical information in the rather grandiloquent essay on Foote prefixed to "Jon Bee's" useful edition of Foote's *Works* (3 vols., 1830). But few readers will care to go further than to the essay on Foote, reprinted with additions, from the *Quarterly Review*, in the late Mr. Forster's *Biographical Essays;* and none can fare better than those who turn to this delightful and discriminating study of a man of real though peculiar genius.

(A. W. W.)

FOPPA, Vincenzo, a painter, was born in Brescia soon after 1400, and died there in 1492. He settled in Milan towards 1425, and was the head of a school of painting which subsisted up to the advent of Leonardo da Vinci. His contemporary reputation was very considerable, his merit in perspective and foreshortening being recognized especially. Among his noted works are a fresco in the Brera Gallery, Milan, the Martyrdom of St. Sebastian; a Crucifix in the Carrara Gallery, Bergamo, executed in 1455; the Trinity, in the church of S. Pietro in Oliveto, Brescia; and other paintings in the same city.

FORAMINIFERA. This designation is part of that given by D'Orbigny in 1825 to an order of animals forming minute calcareous shells (found *recent* in shore-sand, and *fossil* in various Tertiary Limestones), for the most part many-chambered, and often bearing a strong resemblance in form (fig. 1) to those of *Nautilus Orthoceras*, and other chambered Cephalopods,—his (supposed) *Cephalopoda foraminifera* being distinguished from the (real) *Cephalopoda sipunculifera* (Nautilus and its allies) by the want of the "siphon" which passes from chamber to chamber in the latter, and its replacement in the former by mere "foramina" in the dividing septa. And it seems to have been the applicability of this term *Foraminifera* to the *shells* thus characterized which has caused it to be retained as their ordinary designation, notwithstanding that the knowledge since acquired of the *animals* that form these shells necessitates the removal of the group from the elevated position assigned to it by D'Orbigny, to nearly the lowest grade of the whole animal series. It was by the admirable observations upon living *Foraminifera* published by Dujardin, in 1835, that attention was first drawn to the existence of a type of animals more simple than any previously known,—their bodies consisting entirely of an apparently homogeneous semi-fluid substance, to which he gave the name "sarcode;" and this substance projecting itself through apertures of the shell into indeterminate ramifying extensions (which he termed *pseudopodia*), capable of being retracted and fused again (so to speak) into the general mass of the body. Regarding these animals as a section of the large group of *Infusoria*, whose bodies he supposed to have a like simplicity of sarcodic composition, he distinguished them as *Rhizopods*, on account of the root-like character of their pseudopodial extensions.

The general correctness of Dujardin's description of the animals that form Foraminiferal shells has been fully confirmed by subsequent researches; but the larger knowledge since obtained of the nature of the *Protozoa* has led to a more correct apprehension of the relations of the Rhizopoda to the other components of that group. What is now regarded as the simplest type of an animal, designated a *Moner* (see Animal Kingdom, vol. ii. p. 45), consists of an independent particle of the elementary form of living matter known as "protoplasm" (the "sarcode" of Dujardin), which is capable of growth and maintenance by the assimilation of nutrient material, and of multiplying itself either by subdivision or by some modification of that process. Now the first stage of differentiation of this apparently homogeneous substance into histogenetic elements consists in the appearance of certain rounded bodies termed *endoplasts*, which appear to be the equivalents of the *nuclei* of the "cells" whose individuation marks a higher stage of differentiation. And the next stage (well seen in *Amœba*) consists in the differentiation of a more consistent external layer, or "ectosarc," from the less consistent substance of the interior, or "endosarc," in which are observable "vacuoles" containing fluid, of which one or more (that seem bounded by a definite pellicle, and are known as "contractile vesicles") contract and dilate rhythmically. As yet, however, there is no definite point of entrance for alimentary particles, or of exit for excrementitious matter,—nutrient *ingesta* being admitted, and their unassimilable residue being got rid of, through any spot of the ectosarc. It is in the presence of a definite mouth, and usually of an anus also, that even the simplest of the true ciliated *Infusoria* show a decided advance upon the "rhizopodal" type,—an advance which is still more marked in the higher *Infusoria* by the complexity of their internal organization.

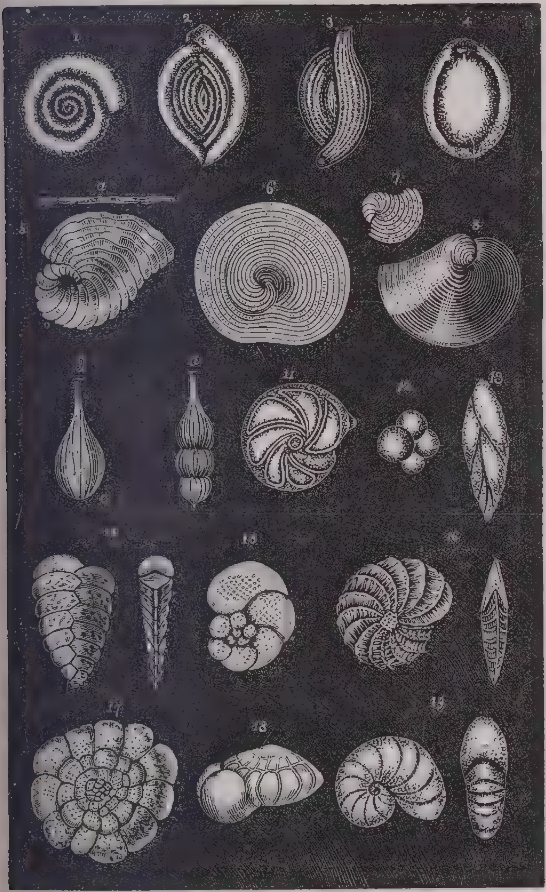

Fig. 1.—Various forms of *Foraminifera*:—1, Cornuspira; 2, Spiroloculina; 3. Triloculina; 4, Biloculina; 5, Peneroplis; 6, Orbiculina (cyclical); 7, Orbiculina (young); 8, Orbiculina (spiral); 9, Lagena; 10, Nodosaria; 11, Cristellaria; 12, Globigerina; 13, Polymorphina; 14, Textularia; 15, Discorbina; 16, Polystomella; 17, Planorbulina; 18, Rotalia; 19, Nonionina.

Now the animal bodies of *Foraminifera*, notwithstanding the regularity and complexity of the shells they form, show but a very slight advance on the simplest moneral type. For their protoplasmic substance does not seem to be differentiated into "ectosarc" and "endosarc,"—every part of it alike projecting itself into pseudopodial extensions, and these extensions being capable, not only of dividing and ramifying indefinitely, but also of reuniting by mutual fusion when they come into contact with each other, so as to constitute an irregular network (figs. 2, 3, 4). It is on account of this last peculiarity that the writer has distinguished the *reticulose* forms of the Rhizopod type from the *lobose* (consisting of *Amœba* and its allies) on the one hand, and from the *radiolarian* (of which *Actinophrys* is the type) on the other. The sarcodic bodies of *Foraminifera* were believed until recently to have neither "nuclei" nor "contractile vesicles;" but as the observations of Hertwig and F. E. Schulze have established the presence of these in some instances (the writer also having observed "endoplasts" in *Orbitolites*), it is probable that they exist universally.

The attention which has been given in recent years to the study of *Foraminifera* has invested the group—formerly considered as comparatively insignificant—with a new interest and importance. For (1) these minute testaceous Rhizopods, instead of having mere local *habitats*, are diffused abundantly through all save polar seas, and seem to do the first work of collecting by imbibition, and of converting into living substance, the organic matter which is contained, however sparingly, in all oceanic water, and the restoration of which, as fast as it is thus withdrawn, is effected by the various forms of marine vegetation.[1] Again (2), without anything that can be called organization, the protoplasmic bodies of these animals give origin to protective casings of marvellous regularity of form, and often of great complexity of structure,—these being sometimes "tests" built up by the apposition of sand-grains or other particles collected from the bottom on which they live, the animals only furnishing the cement by which they are held together, but being more often true "shells," formed (like the skeletons of higher animals) by an interstitial deposit of carbonate of lime drawn from the surrounding medium, in the substance of living tissue. Notwithstanding (3) the absence of any perceptible differences in the character of the animals they respectively contain, these protective casings, whether sandy "tests" or calcareous "shells," present a wide diversity of fundamental form, which is almost indefinitely augmented by subordinate modifications; and these modifications are generally so gradational as to render it impossible (when a sufficient number of specimens are compared) to draw any lines of separation between what appear, when only the extremes are regarded, to be clearly differentiated types. And this is true, not merely of *species* (which in the sense of constantly differentiated races cannot be said to have any existence among *Foraminif-*

---

[1] That all *marine* animal life must ultimately depend upon *marine* vegetation is as certain as that all the animal life of the *land* ultimately depends upon *terrestrial* vegetation. And looking to the very large proportion which, not only among Fishes, but also in the higher Mollusca, Crustacea, and Echinodermata, the carnivorous bear to the phytophagous types, and to the abundance of the former on bottoms far too deep for the growth of the Algæ required for the sustenance of the latter, and on which there is no "raining down" of Diatoms from the surface (as in polar areas), it seems obvious either that there must be animals capable of generating organic compounds for themselves out of the gases contained in ocean-water, or that it must itself supply nutrient material in the liquid form to animals specially adapted to imbibe and assimilate it. Of the possibility of the former hypothesis we have no evidence whatever; and in the absence of light at great depths, any new production of organic compounds seems almost inconceivable. On the other hand, the analyses made by Dr. Frankland of the specimens of ocean-water brought home in the "Porcupine" expedition of 1869 have shown that it always contains an appreciable proportion of nitrogenous matter; while in *Foraminifera* there seems to be a special capability of imbibing and assimilating such matter by the extension of the soft body into a protoplasmic network, exposing a very large surface. Of the importance of this provision (first suggested by Sir Wyville Thomson) in the economy of nature the following is an apt illustration:—Large quantities of cod are taken by fishermen on the Faroe banks, attracted

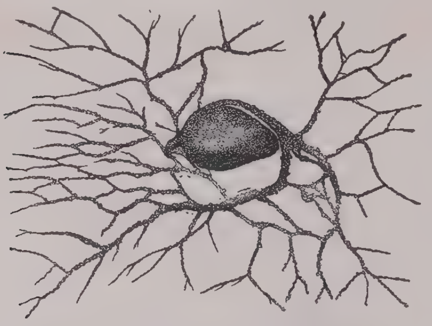

FIG. 2.—*Lieberkühnia*, with reticular pseudopodia.

era), but also of what would elsewhere be accounted *genera;* whilst even *families* cannot, as a rule, be sharply defined, many of them containing aberrant forms that defy all attempts at strict limitation. In fact, it would be scarcely a figure of speech to say that, within each of the three primary subdivisions of the group to be presently marked out, every form passes gradationally into every other. Hence the study of *Foraminifera*—whose small (but not *too* small) size and numerical abundance are peculiarly favorable to the comparison of large series of individuals—affords a most valuable lesson in taxonomy,—giving the best illustration that the whole animal kingdom can afford of the production of almost endless varieties of conformation by "descent with modification." Looking (4) to the almost universal diffusion of existing *Foraminifera*, and to the continuous accumulation of their calcareous *exuviæ* over vast areas of the ocean-bottom, there can be little doubt that they are at present doing more than any other tribe of marine animals to separate carbonate of lime from its solution in sea-water, so as to restore to the solid crust of the earth what is being continually withdrawn from it by the solvent action exerted by rain and rivers upon the calcareous material of the upraised land. And when (5) we look back into the past history of our globe, we not only find conclusive proof of the enormous contributions which *Foraminifera* have made to the calcareous strata of Tertiary and Secondary epochs (Nummulitic Limestone and Chalk having been almost entirely formed by their agency), but encounter strong reason for the belief that the principal mass of the Palæozoic Carboniferous Limestone had a similar origin. And when finally (6) we go still further back in geological time, and bring our knowledge of this type to bear on the very earliest calcareous formation that has yet been found in stratified rocks (the Serpentine Limestone of the Canadian Laurentians), we find distinct evidence that this also had its origin in Foraminiferal growth; which has thus stamped the impress of its existence even upon the oldest of those Archaic rocks, which, through a long subsequent succession, have as yet yielded no other distinct evidence of the existence of either animal or vegetable life on our planet, And thus in all parts of the geological series we not only recognize the constructive work of these humble organisms, but, interpreting the past by the present, find ever-increasing reason to believe that it has exceeded that of all other marine animals taken collectively.

A concise statement of the evidence in support of each of these positions will be embodied in the following sketch of the life-history, present and past, of this group; which will be so drawn as rather to bring into view its great features of general interest, than those details with which the systematist only is concerned.

Although the testaceous *Foraminifera* are all marine, certain shell-less animals essentially similar in nature occur in fresh water; and these, of which *Lieberkühnia* (fig. 2) is a characteristic example, afford the best means of studying the life-history of the "reticulose" type. In its inactive state *Lieberkühnia* is an ovate corpuscle of granular protoplasm about 1-400th of an inch in diameter, not presenting either any distinct differentiation of "endosarc" and "ectosarc" or "contractile vesicle," or any evident "nucleus," but including a large number of vacuoles filled with a homogeneous liquid. In its active state, on the other hand, the body puts forth a sort of stem, which soon branches irregularly into pseudopodia; and these subdivide and ramify with great minuteness to an extent two or three times as great as that represented in the figure, the ramifications coalescing whenever they come into contact with each other, so as to form an irregular network which may be compared to an animated spider's-web. This network serves to entangle either minute particles (such as chlorophyll granules) or larger bodies (such as Infusoria) that come in its way,—the former being transmitted to the central body by a sort of circulation (closely resembling the *cyclosis* of vegetable cells) which is constantly going on through the whole protoplasmic network, and the latter becoming enclosed in a kind of sheath formed by the blending of the neighboring pseudopodia, which apply themselves to its surface and draw it into the central mass by their gradual contraction. Although destitute of any protective envelope, *Lieberkühnia* does not put forth its pseudopodia indifferently from any part of its surface,—their primary stem being enveloped in a transparent sheath, which may be traced as a thin pellicle over the whole body.

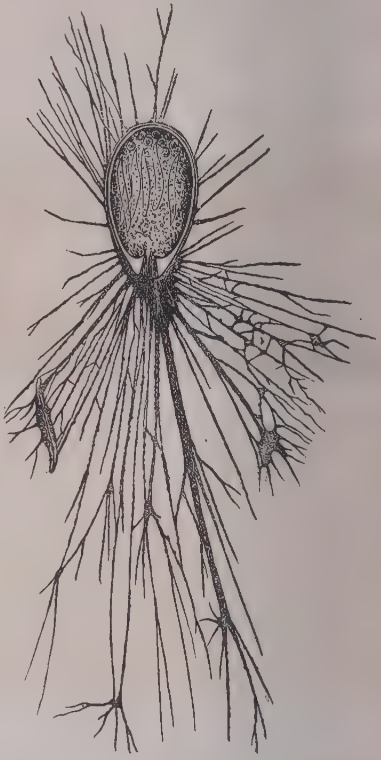

FIG. 3.—*Gromia*, with extended pseudopodia.

And in *Gromia* (fig. 3), of which some forms inhabit fresh water (attaining a size that renders them visible to the naked eye), whilst others are marine, this pellicle is thickened into a distinct casing or "test" of ovoidal shape (probably composed of chitin[1]), with a single round orifice of

---

thither by the abundance of star-fish, on which they greedily feed; and the stomachs of these star-fish are found to be filled with *Globigerinæ*. Thus man is dependent for this "harvest of the sea"—in the first place upon the star-fish that feed the cod; secondly, on the foraminifers that feed the star-fish; thirdly, on the organic material (in very weak solution) which ocean-water supplies to the foraminifers; and finally, on the various forms of marine vegetation by which this supply is continually being renewed. The writer deems it probable that the same function is performed by *Sponges*, whose ramifying internal canal-system provides a vast extent of absorbent surface, and that this is the explanation of the otherwise singular fact, that the "cold-area" (temp. 30° Fahr.), not far from the Faroe banks, swarms with various types of boreal Echinoderms, notwithstanding the almost entire absence of *Foraminifera* caused by the depression of temperature, their place being taken by a particular type of *Sponge* which there finds a congenial *habitat*, and probably supplies food to higher marine animals.

[1] There seems reason for regarding this as representing the "cellu

moderate size, through which the sarcodic body puts forth its pseudopodial extensions. When the animal is in a state of repose, these are entirely retracted into the test; but when its activity recommences, they are put forth from its orifice, as from the stem of *Lieberkühnia*, and form a sarcodic network which is in a state of incessant change—new centres of radiation often arising where two or more pseudopodia coalesce, by the flowing of the protoplasm towards those points. It is specially noticeable in this type that the sarcodic body extends itself over the entire surface of the test, so as completely to enclose it, and that pseudopodia are put forth from every part of this extension, being especially numerous at the posterior end, where they probably serve to fix the test, and thus to enable the animal to put forth more power in seizing the larger creatures that serve as its food. For whilst it is partly nourished by the minute granules that adhere to its outspread network, it lays hold of the smaller Infusoria and Diatoms, the zoospores of Confervæ, etc., and draws them entire into the interior of the test, within which their indigestible remains may frequently be seen. Now, if the transparent pellicle of *Lieberkühnia* were consolidated by calcareous instead of by chitinous deposit, a monothalamous (single-chambered) "shell" would be produced (9 in fig. 1), such as constitutes the permanent form of the simplest *Foraminifera*, and the primordial form of even the most complex. This shell, like the test of *Gromia*, may have but a single aperture, from which the pseudopodial extensions are put forth, and through which alone nutriment is received into the contained body. But in a large portion of the polythalamous (many-chambered) *Foraminifera* (fig. 4), the shell-wall is perforated with minute pores over its entire surface, through which pseudopodia extend themselves in a radial direction; and while the coalescence of these at their origin forms a continuous sarcodic layer that covers the exterior of the shell, the coalescence of their extremities forms new centres of radiation at a distance from it. The aperture or mouth in these types is much smaller than in the preceding, and appears to serve rather for the projection of the stolon-process, by which new chambers are formed (in the manner to be presently described), than for the introduction of nutriment. And when it is considered that the diameter of the pores of the shell never exceeds 1-5000th of an inch (being often much less than 1-10,000th), and that the chlorophyll-granules, zoospores, etc., that nourish the fresh-water Rhizopods are altogether wanting in the sea-depths inhabited by the higher types of *Foraminifera*, there seems additional ground for the doctrine already propounded, that the nutrition of the animals of this group is mainly drawn rather from the organic matter that is dissolved in the medium they inhabit, than from solid particles suspended in it.

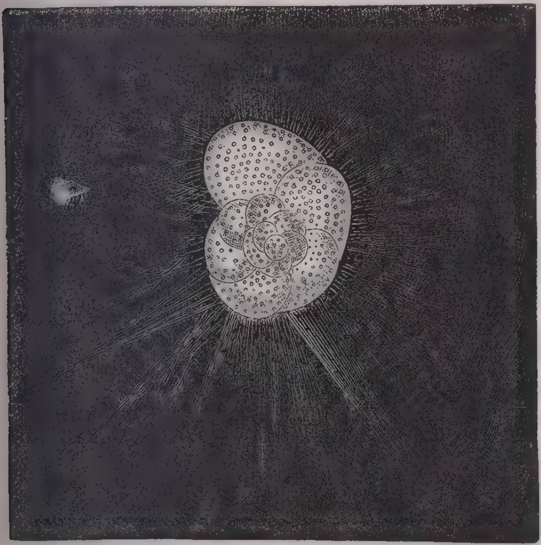

FIG. 4.—*Rotalia*, with pseudopodia extended through the pores of the shell.

In regard to the propagation of *Foraminifera*, little is as yet certainly known. The growth of the individual may proceed, as will be presently shown, to an almost indefinite extent, by the gemmiparous multiplication of the segments or divisions of its body, with a corresponding multiplication of the chambers of its shell; but it more frequently happens that when the organism has attained a certain limited size, the new segments detach themselves, each one growing into the likeness of its parent; and this is probably the ordinary way in which the continuance of the race is provided for. But it would also seem that under certain circumstances the sarcodic body of the parent breaks itself up into segments, each containing an "endoplast" or "nucleus," and that around each of these a shelly covering is formed while it is still enclosed within the original shell, the offspring finally escaping by its rupture. Whether this mode of propagation is preceded by any process of "conjugation," and is thus related to sexual generation, is still undetermined.

By far the greater number of *Foraminifera* are *composite* fabrics, evolved from a simple protoplasmic body by a process of continuous gemmation, each bud remaining in connection with the stock from which it was put forth; and according to the plan on which this gemmation takes place, will be the configuration of the composite fabric thereby produced. Thus if the bud be put forth from the aperture of the monothalamous *Lagena* (9 in fig. 1) in the direction of the axis of its body, if a second chamber be formed around this bud in continuity with the first (receiving the neck of the latter into its own cavity), and if this process be successionally repeated, it is obvious that a straight rod-like shell (10 in fig. 1) will be produced, having a series of chambers communicating with each other by the apertures that originally constituted their mouths, and opening externally by the mouth or aperture of the last formed chamber. The successive segments may be all of the same size, or nearly so; in which case the entire series may either resemble a string of beads, or may approach the cylindrical form, according to the shape of the chambers. But it more frequently happens that each segment somewhat exceeds its predecessor in size, so that the entire shell has a somewhat conical shape. If, on the other hand, the axis of growth should be slightly curved instead of straight, the resulting composite shell will be arcuate, while a more rapid deflection gives it a spiral curvature (5 and 11 in fig. 1). The form of the spire will depend in the first place upon whether its convolutions lie in the same plane, like those of a *nautilus*, so that the shell is equilateral (16 and 19 in fig. 1), or pass obliquely round a vertical axis, as in a *snail*, so that the shell becomes "inequilateral" (18 in fig. 1), having a more or less conical form, with the primordial chamber at its apex. In other cases, again, the vertical axis is greatly elongated, and the number of chambers forming each revolution around it is reduced to four, three, or even two (13 and 14 in fig. 1). But further, the spiral plan of growth may give place to the cyclical, successive circles of new chambers being formed around the interior growth, so as to give the shell a discoidal shape (6 and 17 in fig. 1). And sometimes all regularity of plan disappears in the later stages of growth, new chambers being added in various directions, so that the fabric becomes "acervuline."

In the older classifications of *Foraminifera*, these differences of plan of growth were adopted as characters of primary importance in the subdivision of the group. But it has now become obvious that comparatively little value is to be attached to them. For to associate together all rectilineal, all spiral, and all cyclical *Foraminifera*, is not only to run counter to the indications of natural affinity that are furnished by the intimate structure of the shell, the conformation of the individual chambers, and the mode of their intercommunication, but to set at naught two general facts of fundamental significance,—*first*, that one plan of growth often graduates insensibly into another, as does the straight into the spiral in the group of which 10 and 11 of fig. 1 are extreme forms; and, *second*, that it is not at all uncommon for the plan to change during the growth of one and the same individual,—the spire, for example, either straightening itself out, so as to revert to the rectilinear

lose wall" of the vegetable cell; which, in the curious *Chlamydomyxa* of Archer, opens at a certain stage of its life, and allows its protoplasmic contents to project themselves into a "reticulose" extension.

type, or returning into itself so as to make a complete circle, round which a succession of concentric annuli is then produced on the cyclical type, while the original regularity is sometimes lost altogether in the "acervuline" piling up of the later-formed chambers. On the other hand, the fundamental importance of the *perforation* or *imperforateness* of the external envelope, as affecting the physiological condition of the contained animal, is now universally admitted. For where (as in *Peneroplis*, 5 in fig. 1) that envelope, whether composed of calcareous shell or built up by the cementation of sand-grains, has no other communication with the exterior than by the single or multiple aperture of the last chamber through which the whole pseudopodial apparatus of the contained animal is put forth, the nutrition of the entire segmental body that occupies the previously formed chambers must be carried on by a continual interchange of protoplasmic substance extending through the entire mass, however great may be the multiplication of its segments. Where, on the other hand (as in *Rotalia*, fig. 4), the wall of each chamber is perforated for the passage of pseudopodia, the segment it contains is thereby placed in direct communication with the surrounding medium from which it derives its sustenance, so as to be independent of the remainder of the series. The "imperforate" calcareous shells of *Foraminifera* are also termed "porcellanous," from the opaque-white aspect they present when viewed by reflected light; though, when thin, they show a rich brown hue by transmitted light. Even under a high magnifying power, their substance appears entirely homogeneous. The perforated shells, on the other hand, having an almost glassy transparence (except where this is interrupted by tubulation), are known as "vitreous" or "hyaline." Where the shells are thin, the perforations are simply *pores* (fig. 4); but where they are thick, the perforations are *tubules* usually running straight and parallel from surface to surface (fig. 24).

Thus, then, the *Foraminifera* are naturally divisible in the first instance into two groups, the *Imperforata* and the *Perforata;* the former of which is again divisible into the *Arenacea*, which build up "tests" by the aggregation of sand-grains, and the *Porcellanea*, which form porcellanous shells; whilst the latter, *Vitrea*, includes all the perforate types. There is often a very curious parallelism between the forms contained in these three series respectively, still more between certain "porcellanous" and certain "vitreous" types; but this arises in each case from similarity in plan of growth, and does not indicate any real affinity. In fact the two calcareous-shelled series may be compared to two trees of different orders, which resemble each other in their mode of branching, but have dissimilar leaves and flowers.

I. Arenacea.—The calcareous shells of certain types of *Foraminifera*, alike in the "porcellanous" and in the "vitreous" series, are not unfrequently covered with sand-grains, cemented into the surface-layer of the true shell-substance. But in the group now to be described, the casing of the body is entirely composed of foreign particles (usually grains of sand, but sometimes minute *Foraminifera*, sponge-spicules, etc.), the animal furnishing nothing save the cement that holds them together; and in its lowest forms no special cement seems to be supplied, the sand-grains being simply imbedded in the sarcodic substance of the body. The increased attention which has of late been given to this group (our knowledge of which has been largely augmented by deep-sea dredging) seems to justify our regarding the "arenaceous" type as on the whole less advanced than either the "porcellanous" or the "vitreous,"—its lowest forms presenting a condition less specialized than even the simplest of the calcareous-shelled *Foraminifera*, whilst its highest, although sometimes attaining a comparatively gigantic size, build up their massive "tests" upon a very simple plan, exhibiting no approach to the complexity of structure to be found in the "shells" which some of them closely resemble in external form. A few of the more interesting types of the *Arenaceous* group will now be briefly noticed.

In the sandy mud which covers certain parts of the bottom of the 500-fathoms channel between the north of Scotland and the Faroes, the large monothalamous *Astrorhizæ* are so abundant as sometimes to form a great part of the contents of the dredge. Their typical shape (as the name implies) is discoidal with stellate radiations; but they are sometimes globular, sometimes cervicorn, and present every intermediate gradation between these forms. The "test" is composed of loosely aggregated sand-grains, not held together by any mineral cement; and it is *destitute of any definite orifice*, so that the sarcode-body (of a dark green color) which occupies the cavity must put forth its pseudopodial extensions between the sand-grains of its test. But there is, in the writer's belief, a lower form even than this. For in the same dredgings there were found a number of little globular masses varying in size from a pin's head to a large pea, formed of aggregations of sand grains, foraminiferal shells, etc., held together by a tenacious protoplasmic substance, without any definite structural arrangement. And although these might be supposed to be mere accidental agglomerations, yet there seems adequate reason for regarding them as living organisms of the simplest possible "monerozoic" type. For just as a simple "moner," by a differentiation of its homogeneous protoplasm, becomes an *Amœba*, so would one of these undifferentiated mixtures of sand and protoplasm, by the separation of its two components—the sand being limited to the superficial layer, so as to form an investing "test," of which the whole interior is occupied by the sarcode-body alone,—become an *Astrorhiza*.

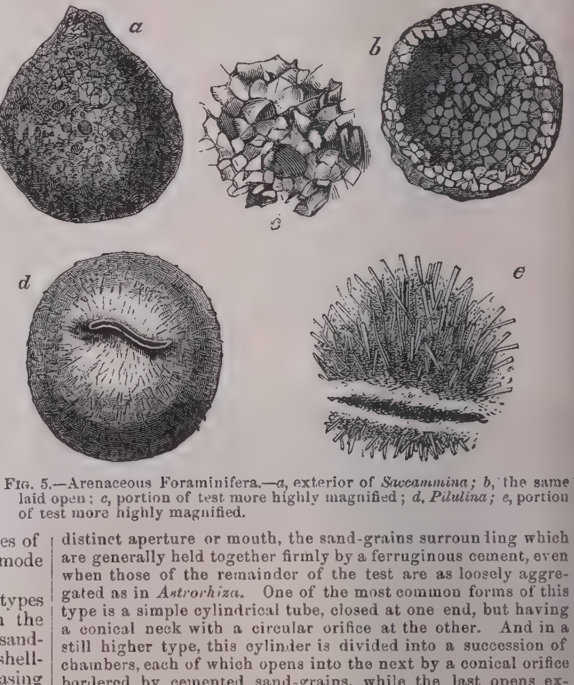

Fig. 5.—Arenaceous Foraminifera.—*a*, exterior of *Saccammina; b*, the same laid open; *c*, portion of test more highly magnified; *d*, *Pilulina; e*, portion of test more highly magnified.

The next degree of elevation is shown in the presence of a distinct aperture or mouth, the sand-grains surrounding which are generally held together firmly by a ferruginous cement, even when those of the remainder of the test are as loosely aggregated as in *Astrorhiza*. One of the most common forms of this type is a simple cylindrical tube, closed at one end, but having a conical neck with a circular orifice at the other. And in a still higher type, this cylinder is divided into a succession of chambers, each of which opens into the next by a conical orifice bordered by cemented sand-grains, while the last opens externally by a like orifice,—thus sketching out the "nodosarine" type of the "vitreous" Foraminifera, but on a much larger scale.

In the more advanced Arenaceous types, on the other hand, the sand-grains of the entire "test" are firmly united together by a cement composed of *phosphate of iron*, which must be exuded from the sarcodic body of the animal, its materials being originally derived from the sea water. In some instances the sand-grains selected are of such minute size that, when worked up with the cement, they form a sort of "plaster," the surface of which is quite smooth, both externally and internally. This is the case with the genus *Trochammina*, under which is ranged a whole series of forms ranging from a simple undivided tube to a perfect helical spire resembling a Catherine-wheel (whence the name given to the genus), and thence, by the alteration of its spire to the turbinoid, and by the subdivision of its cavity into chambers, to the "rotaline" type. In other instances the sand-grains are somewhat larger, but are apposed with such extraordinary regularity, and cemented together so artificially, as to form a most delicate but firm test of very uniform thickness, perfectly smooth both externally and internally. Tests of this kind present a singular series of adumbrations of the "orbuline," "globigerine," and "nodosarine" types of the vitreous series. In other cases, again, the sand-grains being larger, the "test" is constructed more coarsely, but still with remarkable symmetry. One of the most interesting of the simple coarse-grained forms is the little *Saccammina spherica*, whose flask-shaped tests (fig. 5, *a*, *b*) of the size of minute seeds, with prolonged necks and circular apertures, now found living abundantly in particular localities, have been also distinctly recognized in Carboniferous Limestone. That the size of the sand-grains used in the construction of such tests is not accidental (depending on the fineness of division of the sandy bottom on which the animals live), but is the result of selection on the part of the animals that use them, is shown not only by the fact that coarse-grained and fine-grained "tests" are brought up from the same bottom, but by the very curious difference in the materials used to form two kinds of tests nearly of the same size and of corresponding simplicity of type. The very same deep dredgings which yielded *Saccammina* brought up a number of other monothalamous spherical tests, filled with dark green sarcode, to which the name *Pilulina* has been given from their resemblance to homœopathic globules (fig. 5, *d*). These, instead of being constructed by the cementation of sand-grains, are composed of a sort of felt (*e*) made by the regular "laying" of siliceous fibres (the fine-pointed ends of elongated spongo spicules) with very minute sand grains dispersed among them; and the aperture, instead of being a round hole at the end of a short neck, is a sigmoid fissure with somewhat projecting lips. The constancy of these differences indicates a dissimilarity in the "potentialities" of the animals of the respective types, of which we find no indication in their apparently-homogeneous sarcodic bodies.

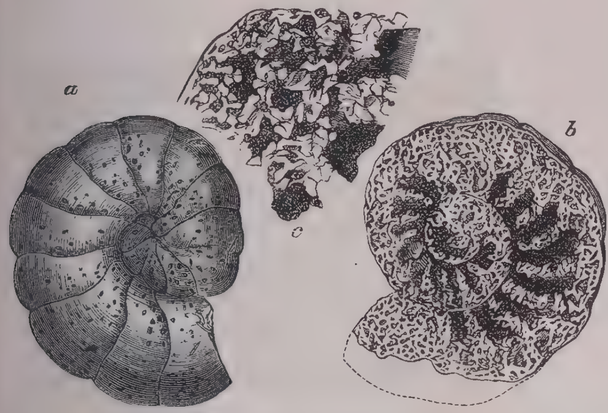

Fig. 6.—Nautiloid *Lituola*. *a*, exterior; *b*, chambered interior; *c*, portion of labyrinthic chamber-wall, showing component sand-grains.

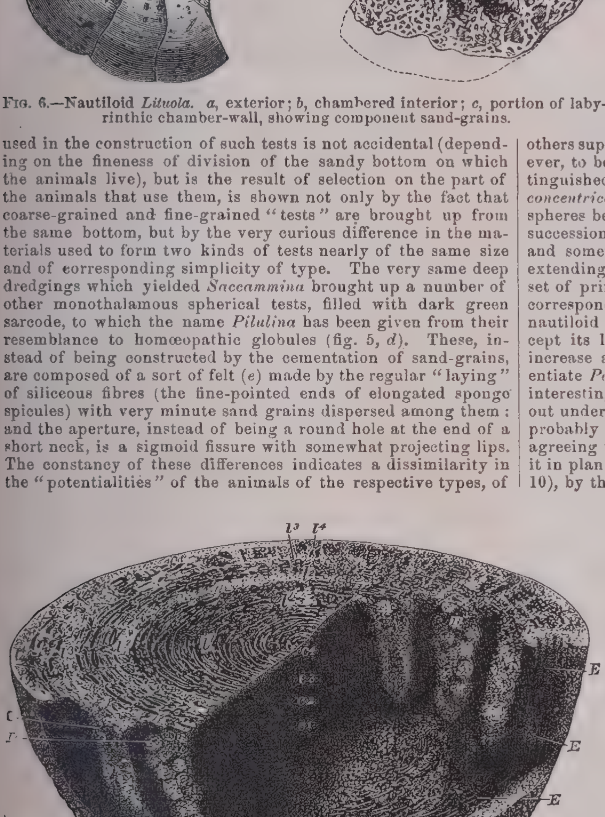

Fig. 7.—General view of the internal structure of *Parkeria*. In the horizontal section, l^1, l^2, l^3, l^4, mark the four thick layers; in the vertical sections, A marks the internal surface of a layer separated by concentric fracture; B, the appearance presented by a similar fracture passing through the radiating processes; C, the result of a tangential section passing through the cancellated substance of a lamella; D, the appearance presented by the external surface of a lamella separated by a concentric fracture which has passed through the radial processes; E, aspect of section taken in a radial direction so as to cross the solid lamella and their intervening spaces; c^1, c^2, c^3, c^4, successive chambers of nucleus.

The highest development of this type known to exist at the present time is shown in the large polythalamous "nautiloid" forms which have been brought up in considerable abundance from depths mostly ranging between 200 and 500 fathoms. The test (fig. 6, *a*) is for the most part composed of coarse sand-grains firmly cemented to each other; but it is generally smoothed over externally with a kind of "plaster" resembling that of which the "trochammine" tests are made up. On laying open the spire, it is found to be very regularly divided into chambers by partitions formed of cemented sand-grains (*b*), a communication between these chambers being maintained by a fissure left at the inner margin of the spire. So far, the plan of structure accords with that of the smaller "nonionine" forms (resembling 19 of fig. 1), which are found at much greater depths, ranging downward to more than three miles. But this more developed form is characterized by the extension of the principal cavity of each chamber into passages excavated in its thick external wall,—each passage being surrounded by a very regular arrangement of sand-grains, as seen at *c*. This "labyrinthic" structure is of great interest, from its relation on the one hand to the still higher development of the like structure in the large fossil *Lituola* of the chalk, whose crozier-like "test" has its principal chambers subdivided into "chamberlets," and on the other hand to that of two gigantic fossil *Arenacea*, one of the Cretaceous and the other of early Tertiary age.

Geologists who have worked over the Greensand of Cambridgeshire have long been familiar with solid spherical bodies, varying in size from that of a pistol-bullet to that of a small cricket-ball, which there present themselves not unfrequently, and have been regarded by some as mere mineral concretions, whilst others supposed them to be fossilized Sponges. They prove, however, to be "tests" of Arenaceous Foraminifera, which are distinguished from all other known foraminiferal types by their *concentrically-spherical* plan of growth (fig. 7),—the successive spheres being formed around a "nucleus," which consists of a succession of chambers arranged sometimes in a straight line and sometimes in a spiral, the last of them opening out and extending itself over its predecessors. Each sphere contains a set of principal chambers, with labyrinthic extensions of them, corresponding in all essential particulars with those of the nautiloid *Lituola* just described; so that there is nothing except its large size (which simply results from continuity of increase and spherically-concentric plan of growth) to differentiate *Parkeria* from ordinary *Foraminifera*. It is not a little interesting to find the very same plan of construction carried out under a different form in another gigantic fossil Arenacean, probably of the early Tertiary period, termed *Loftusia*; which, agreeing with *Parkeria* in all essential particulars, differs from it in plan of growth, *Loftusia* being formed, like *Alveolina* (fig. 10), by the rolling of a spiral round an elongated axis.

The discovery of these two singular types greatly enlarges our conceptions of the Arenaceous group, and shows how little justification there is for any attempt to lay down *a priori* restrictions as to the supposed "possibilities" of Foraminiferal organization.

II. Porcellanea.—In the sketch now to be given of the "porcellanous" series, it will be the writer's object to show the closeness of the relation between its simplest and its most complex and diversified forms (which he regards as all constituting but a single family, the *Miliolida*), and to indicate the chief of those gradational transitions by which a continuous affinity is established between them all.

Passing by the proteiform *Nubecularia*,—the tent-like incrusting shells of which rudely foreshadow almost every plan of growth to be met with among higher Foraminifera,—we commence with the simple *Cornuspira* (1 in fig. 1), whose spirally-coiled undivided tube, the exact isomorph of the helical arenaceous *Trochammina*, attaches itself to the Zoophytes and Sea-weeds of the British coasts. In full-grown specimens, the later turns of the spire generally flatten themselves out like those of *Peneroplis* (5 in fig. 1), so that the form of the mouth is changed from a circle to a long narrow slit. From this simple undivided spire we may pass along two divergent lines, one conducting us to the *milioline* and the other to the *orbiculine* type, and the latter again leading us to the *orbitoline*, in which the spiral plan of growth gives place in the very earliest stage to the cyclical. The shells of the *Miliolæ* (so named from their resemblance to millet-seeds) are at present found in the shore sands of almost every sea; and they accumulated in certain localities during the early Tertiary period to such an extent as to form massive beds of limestone. Their typical forms (3 and 4 in fig. 1) are composed of a succession of elongated chambers, usually arranged bi-serially on the opposite sides of a straight axis (3 in fig. 1), at one of the ends of which each chamber opens forwards into that which follows, whilst at the opposite end it opens backwards into that which preceded, the aperture in either case being partially closed by a "tongue" or "valve" (which may be considered an imperfect septum), as shown at 4, fig. 1. Indications of such a division may be sometimes noticed even in *Cornuspira,* but it shows itself fully in *Spiroloculina,* in which the spire has the form of an ellipse, at the two ends of whose major axis the new chambers commence alternately. The spiral plan of growth here remains obvious throughout; but in the typical Miliolines (3 and 4 in fig. 1) it is more or less obscured by the extension of the later chambers over the earlier, giving rise to the varied forms which have been distinguished under the generic names of *Biloculina, Triloculina,* and *Quinqueloculina,* according to the number of chambers visible externally. The extreme inconstancy, however, which is found to mark this distinction when large numbers of specimens are compared, entirely destroys its value as a differential character. Milioline shells, though frequently quite smooth, often show some kind of "sculpture," their surface being sometimes more or less deeply "pitted," sometimes regularly honeycombed, and sometimes longitudinally ribbed; and these diversities have been largely used for the characterization of species. Here again, however, the examination of a sufficiently large collection shows the futility of any such differentiation, since every gradation is found between the smooth and the most sculptured forms, while it is not at all uncommon for one and the same shell to be smooth on some parts of its surface, and deeply pitted, honeycombed, or ribbed on others—making it obvious that such differences have no more than a *varietal* significance. There is not, in fact, any group in the whole Animal Kingdom of which the study is more instructive than that of the *Miliolines,* in regard to the *extent of variation* which is compatible with conformity to a fundamental type.

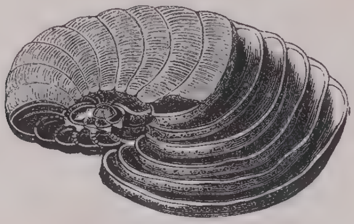

FIG. 8.—*Peneroplis.*

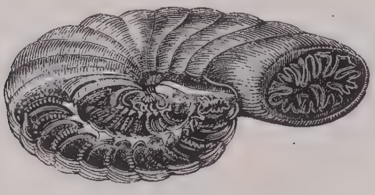

FIG. 9.—*Dendritina.*

The culminating form of the Milioline type may be considered to show itself in *Fabularia,* a fossil of the Paris Tertiaries not known to exist at present, in which the principal chambers are subdivided into "chamberlets," as in *Orbiculina* and *Orbitolites,* and the aperture is cribriform instead of single, the chamberlets opening externally by separate pores.

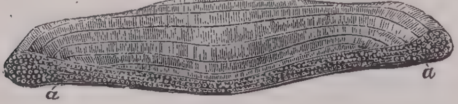

FIG. 10.—*Alveolina:*—*a, a,* septal plane, showing multiple ranges of pores.

The undivided helical tube of *Cornuspira,* again, graduates through *Hauerina* and the spiral forms of *Vertebralina* into the typical *Peneroplis* (fig. 8), a beautiful little shell that abounds in the shallow waters of many parts of the Mediterranean, and is remarkable alike for its glistening porcellanous surface, for the constancy of the ridge and furrow sculpturing which crosses the intervals between the septa, and for the flattening-out of its spire, and consequent narrowing and elongation of its septal plane (5*a* in fig. 1), which is perforated by a single linear series of pores. In tropical seas, however, this type shows itself under a very different aspect (fig. 9). The spire, instead of being flattened out, is turgid; and the septal plane, instead of being perforated by a linear series of pores, has a single large aperture, the dendritic shape of which has caused the name *Dendritina* to be assigned to this type. Now, although such marked differences between *Molluscan* shells would undoubtedly justify *generic* differentiation, yet among Foraminifera they prove to be not even of *specific* value; for when a sufficiently extensive series of this type is compared, its extreme forms graduate insensibly one into the other. In proportion apparently to the warmth of its *habitat* (the gradation being well seen in the Red Sea examples) the shell becomes less flattened and the septal plane broader, and the single row of pores becomes a double or even a triple series, the pores of different series being sometimes partially confluent. With a further increase in the turgidity of the spire, and with a progressive widening of the septal plane at the expense of its length, the pores lose their linear arrangement, and run together in groups, so as to form several irregularly fissured openings; and it is by the coalescence of these that the single dendritic aperture is formed in those examples whose general shape most nearly approaches that of *Nautilus.* This transition often shows itself in the successive stages of growth of one and the same shell. When we consider the physiological import of this variation, we find that it has no relation to any essential differences in the conformation of the animal,—all that it means being that the sarcodic *pseudopodia,* which issue separately in the one case, issue collectively in the other. It is interesting to remark, further, that in each of these types the spire often straightens itself out, so as to give to the shell the shape of a crozier (these "spiroline" forms being peculiarly common in the Red Sea), and that throughout the entire series the surface-marking is singularly constant.

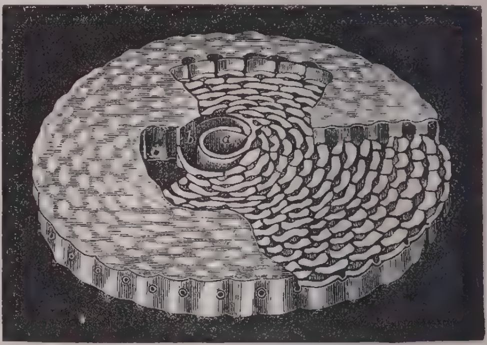

FIG. 11.—Shell of simple type of *Orbitolites,* showing primordial chamber, *a,* and circumambient chamber, *b,* surrounded by successive rings of chamberlets connected by circular galleries which open at the margin by pores.

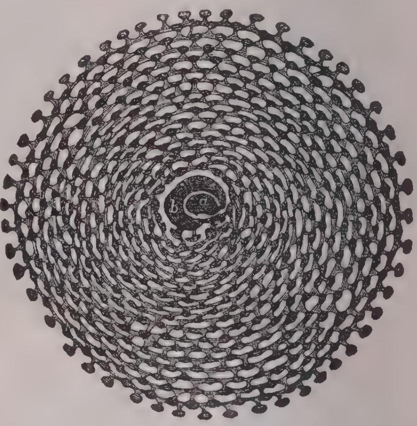

FIG. 12.—Animal of simple type of *Orbitolites,* showing primordial segment *a,* and circumambient segment *b,* surrounded by annuli of sub-segments connected by radial and circular stolon-processes.

From this simply-chambered type we pass on to that in which each chamber is more or less completely divided by transverse partitions (or secondary septa) into a series of "chamberlets," giving to the shell what is designated the "labyrinthic" structure. The first stage of this division, shown in figs. 11, 12, consists in a succession of contractions by which the sarcodic segment that occupies the cavity of each chamber acquires a moniliform or bead-like shape,—the sub-segments into which it is partially subdivided being connected by a continuous band or "stolon." And even where the separation of the chamberlets is most complete, there is still an aperture in each secondary septum, by which the lateral continuity of the sub-segments is maintained. The relation of the labyrinthic *Orbiculina* (6 and 8 in fig. 1), common in tropical seas, to the simple "peneropline" type, is well seen in the early stage (7 in fig. 1) of the former, which is obviously a *Peneroplis* with subdivided chambers. But as age advances, a remarkable change takes place. The later turns of the spire very commonly grow completely over the earlier, so as to make the umbilicus protuberant, as shown at 8 in fig. 1; and their thickness progressively increases by the vertical elongation of the sarcodic "blocks" that occupy their chamberlets into "columns," which communicate with the exterior and with each other through several ranges of marginal pores. In the very large and highly developed forms of this type (attaining a diameter of 7 or 8 lines), which make up the Tertiary Limestone of the Malabar coast, each surface of the spire has a thin layer of chamberlets divided off from the intermediate columnar portion, as in the "complex" type of *Orbitolites* to be presently described.

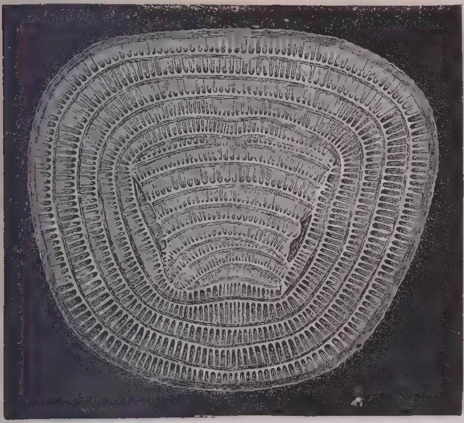

Fig. 13.—*Orbitolite* disk formed around a fragment of a previous disk, by the extension of the growing margin of the fragment along its broken edges.

Now if the axis round which this Orbiculine spire revolves were to undergo such an elongation (by a multiplication of its sub-segments in that direction) as to equal the diameter of the spire, the form would be changed to the globose, with a crescentic septal plane perforated by numerous separate pores; and a yet further increase in the comparative length of the axis would evolve the "fusiform" type characteristic of *Alveolina* (fig. 10), with an elongated and straightened septal plane showing several ranges of separate pores. The largest specimens of this type at present known seldom exceed 0·4 inch in length; and are greatly surpassed by those massive forms of the early Tertiaries whose accumulation in particular localities produced what is now known as the Alveolite Limestone.

Sometimes, on the other hand, even at an early age, the growing margin of *Orbiculina* extends itself laterally at both extremities, so that the two extensions meet on the opposite side of the original spire, which is thus completely enclosed by it. Its growth is thenceforth *cyclical* instead of spiral, concentric rings (each of them answering to one of the chambers of Peneroplis) being successively added, as shown at 6 in fig. 1, and the chamberlets into which they are subdivided opening by separate pores, usually arranged in several series, around the whole margin of the disk. Now, this is the plan of growth characteristic of *Orbitolites*, a type first known as fossil (abounding in the *Calcaire grossier* and other calcareous Eocene strata), but of which living forms have been since found abundantly in tropical and sub-tropical seas, frequently attaining a diameter of 8-10ths of an inch, and a thickness approaching 1-6th. While marginal portions of the disks of the cyclical *Orbiculina* could not be distinguished from those of certain forms of *Orbitolites*, there is such a difference in their origins and early histories as necessitates their generic separation. For in the typical Orbitolite the plan of growth is *cyclical* from the first, successive rings being formed around a "nucleus," which is never overlaid by later growths; and this nucleus consists of a "central" segment (*a*, figs. 11 and 12), which is more or less completely surrounded by a "circumambient segment" (*b*), that gives off numerous radiating stolon-processes to form the first ring of sub-segments. It is a fact of no small morphological interest, however, to find among the varietal forms of this type a distinct reversion to the *spiral* origin,—the most complete example of it being presented in the deep-sea *O. tenuissimus*, whose "nucleus" resembles a *Cornuspira* of three or four turns, of which the last turn rapidly opens itself out, showing a primary division into chambers and a secondary into chamberlets, thus distinctly connecting with the ordinary Milioline type the form whose plan of growth appears at first sight most fundamentally different. This plan is most readily apprehended by examining such small "simple" forms of this type (figs. 11, 12) as occur in the Ægean and Red Seas, in which the successive rings continue to be formed on the pattern of the first. Each chamberlet of the shell (fig. 11) is connected by a passage with those on either side of it; and it is from these intermediate passages, not from the chamberlets themselves, that the radiating passages proceed which lead to the chamberlets of the next ring, or which, in the case of the outermost ring, open at the margin between the protuberant walls of the chamberlets. So, in looking at the sarcodic body (fig. 12) of the animal which occupied the shell, we see that it consists of a succession of necklace-like rings, each consisting of an annular cord with bead-like enlargements at regular intervals, and giving off from the intervals between these beads the radiating stolon-processes which give origin to the sub-segments of the next annulus, as shown at the margin of the figure. These, extending themselves laterally at the growing edge of the shelly disk, will coalesce into a continuous cord, and a new ring of shell-structure will be formed by an excretion of calcareous matter from its surface. There is here no differentiation of parts whatever, every ring being a precise repetition (except as to number of parts) of that which preceded it; and in the living condition the semi-fluidity of the sarcode-body will allow of a perfectly free communication being kept up throughout the disk, so that nutrient matter taken in at the margin may be readily conveyed towards the centre The uniformity in the endowments of the segments is shown by

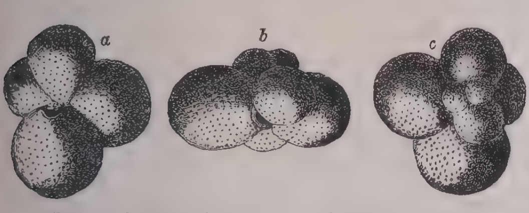

Fig. 14.—*Globigerina bulloides*, as seen in three positions.

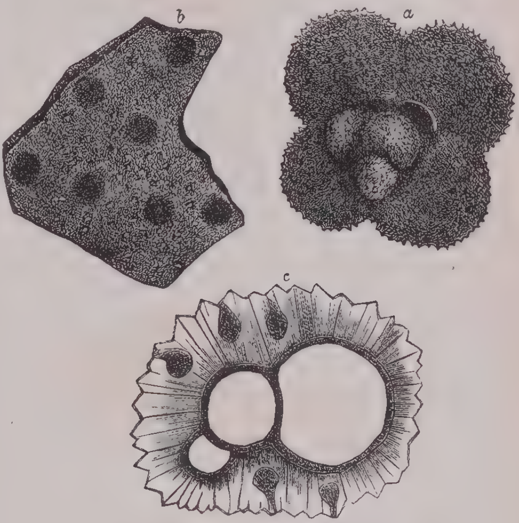

Fig. 15.—*Globigerina* from the Atlantic ooze, showing the thickening of the shell by exogenous deposit:—*a*, entire shell, showing the surface raised into areolated ridges; *b*, portion of shell more highly magnified, showing orifices of tubuli, and large cavities filled with sarcode; *c*, section of shell, showing exogenous deposit formed around the original chamber wall, which is raised into ridges with tubuli opening between them, and includes sarcodic cavities. (After Wallich.)

the fact, of which accident has repeatedly furnished proof, that a small portion of a disk entirely separated from the remainder, will not only continue to live, but will so increase as to form a new disk (fig. 13) whose concentric annuli form themselves regularly around the fragment, obviously by the extension of the annular sarcodic band from its proper growing margin around its whole periphery,—a fact of extreme significance, as showing that even in this elaborately constructed shell the animal body retains its original protoplasmic homogeneousness.

A yet greater complexity of structure presents itself in the large Orbitolite-disks of tropical seas, as also in those of whose fossil remains many Tertiary Limestones are chiefly composed. This complexity depends, in the first place, on the vertical elongation of the sub-segments into a columnar form, so as to produce a progressive thickening of the disk from the centre towards the margin, by which it comes to acquire a somewhat biconcave form: and with this there is an increase in the number of radiating stolon-processes, showing itself in a vertical multiplication of the ranges of marginal pores. The ends of the columns of each ring are connected laterally by two annular cords; and from each of these is given off a series of subsegments, that forms a layer of chamberlets on either surface of the disk, having no communication with those of the intermediate columnar structure except through the annular passages. Even this morphological differentiation does not seem connected with any diversity of function; and a careful comparison of a sufficiently extensive series of forms, from the most simple to the most complex, renders it clear that they are *gradationally connected*, the transition being a process of "evolution," on which heat (probably coupled with a more copious supply of food) exerts an important influence.

III. VITREA.—The vitreous-shelled *Foraminifera* constitute the most elevated division of the group, in regard alike to the high organization of their shell-substance, and to the elaborate construction shown in the shells of its most developed types. And it is in this division that we find the multiplication of individuals accomplishing by far the greater part of those two vast operations now in progress (as they seem to have been through all Geological time of which we know anything), which have been already specified as the great functions of the group:—the extraction from sea-water (1) of the minute quantity of organic matter universally diffused through it, which is converted into a *protoplasmic substance* fit to serve as food for higher animals, and (2) of the minute quantity of *carbonate of lime* held by it in solution, which is solidified into the substance of the shells whose accumulation gives rise to calcareous deposits on the ocean-bottom. The Vitreous *Foraminifera* may be grouped into three families, *Lagenida*, *Globigerinida*, and *Nummulinida*, the typical forms of which are distinguished by well-marked characters.

The chief feature of interest in the Family *Lagenida* is the unbroken succession of forms it presents, from the simple monothalamous *Lagena* to the complex polythalamous *Cristellaria*—all characterized by the very minute tubulation of the shell-substance, and by the circular form of the aperture of each chamber, which has usually an everted lip marked by radiating furrows. The *Lagena* (9 in fig. 1) is a minute flask-shaped shell, with a prolonged neck, having the mouth at its extremity; and its external surface usually presents some form of sculpture, such as prolonged ribs, separate tubercles, or honeycombed areolation. In *Nodosaria* (10 in fig. 1) we find a rectilinear succession of similar chambers, the neck of each received into the cavity of the next; while in *Cristellaria* (11 in fig. 1) a series of progressively enlarging chambers, still presenting the characteristic radiate aperture, is arranged in a nautiloid spiral. These composite types, which are connected by a series of intermediate degrees of curvature, show also the characteristic sculpturing of the simple *Lagena* with an endless variety of modifications; so that there is no group of *Foraminifera* which presents a more complete gradation between extremes so extremely diverse in form and surface-marking that, taken alone, they might fairly be adopted as types of distinct *genera*. Thus, as Mr. H. B. Brady[1] justly remarks, "if the word 'species' is anything more than a conventional term, the whole ought to constitute a single species. But governed by the exigences of a partially artificial arrangement, the modifications embraced in this single unbroken series constitute *thirteen genera*, or almost two entire families, in Professor Reuss's classification; while how many *hundreds*, if not *thousands*, of so-called 'species' have been founded upon the trivial characters above enumerated, it would need much patience to ascertain."

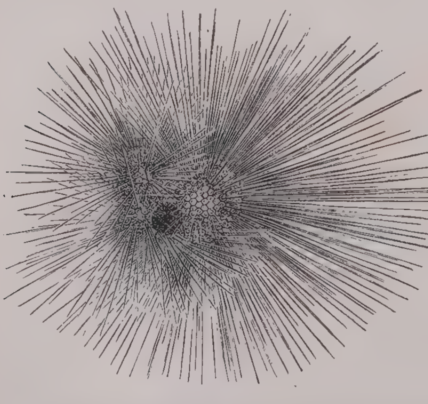

FIG. 16.—*Globigerina*, as captured by the tow-net floating near the surface.

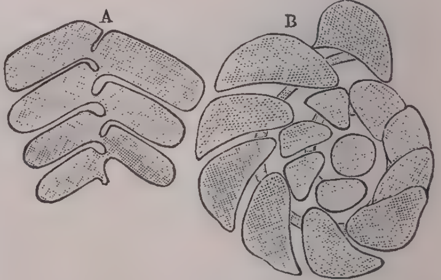

FIG. 17.—Internal casts of Foraminifera:—A, *Textularia*; B, *Rotalia*.

This variability shows itself also in the curious "polymorphism" sometimes exhibited during the growth of one and the same individual, which is especially characteristic of the genus *Polymorphina*. The young shell of this type is obviously made up of lageniform chambers regularly arranged in a double series alternating on the two sides of a rectilinear axis (13 in fig. 1); but from this plan there are often very wide departures in later stages of growth, both in the form and in the arrangement of the chambers—one of the most curious consisting in the backward prolongation of the last chamber over all that preceded it, and its extension into "stags-horn processes," which completely disguise the original conformation. In this aberrant type the characteristic "sculpturing" of the typical *Lagenida* is generally wanting—the shell in its young state being peculiarly thin and glassy: whilst in the large "wild-growing" forms the wall of the outer chamber is usually smooth, and has a porcellanous opacity.

The fundamental characters of the Family *Globigerinida*, which essentially consist in the coarse porosity of the shell (the pores being often $\frac{1}{5000}$th of an inch in diameter), and in the fissured, crescentic, or semioval form of the aperture of each chamber, are well seen in the typical genus *Globigerina*, the principal agent in that production of globigerina-ooze which is now repeating (rather, perhaps, continuing) the formation of the old Chalk. As obtained from the bottom by sounding or dredging, the *Globigerina* presents itself in the form shown in fig. 14—that is, as an aggregation of nearly spherical chambers, having coarsely porous walls like those of *Rotalia* (fig. 4), and cohering externally into a more or less regular turbinoid spire, each turn of which consists of four chambers, progressively increasing in size. These chambers, whose number seldom exceeds sixteen, do not communicate directly with each other, but each has its own separate mouth, opening into a common "vestibule" which occupies the centre of the under-side of the spire. The younger shells, consisting of from eight to twelve chambers, are thin and smooth; but the older shells are thicker, and are raised into ridges that form a hexagonal areolation round the pores (fig. 15, *a*); and this thickening is shown, by examination of thin sections of the shell (*b*) to be produced by an exogenous deposit (corresponding with the "intermediat skeleton" of the more complex types) that invests the origina shell-wall, sometimes containing little flask-shaped cavities filled with sarcode (Wallich). When taken alive by the tow-net, however, floating at or near the surface, the shells of *Globigerinæ* are found to be beset with multitudes of delicate calcareous spines, which extend themselves radially from the angles at which the ridges meet, to a length equal to four or five times the diameter of the shell (fig. 16).

"When the living *Globigerina* is examined under favorable circumstances, the sarcodic contents of the chambers may be seen to exude gradually through the pores of the shell, and spread out until it forms a kind of flocculent fringe round the shell, filling up the spaces among the roots of the spines, and rising a little way along their length. This external coating of sarcode is rendered very visible by the oil-globules, which are oval, and filled with intensely colored secondary globules, and are drawn along by the sarcode, and may be seen with a little care following its spreading or contracting movements. At the same time an infinitely delicate sheath of sarcode, containing minute transparent granules, but no oil-globules, rises on each of the spines to its extremity, and may be seen creeping up one side of the spine and down the other, with the peculiar *flowing* movement with which we are familiar in the pseudopodia of *Gromia*. If the cell in which the *Globigerina* is floating receive a sudden shock, or if a drop of some irritating fluid be added to the water, the whole mass of sarcode retreats into the shell with great rapidity, drawing the oil-globules along with it; and the outline of the surface of the shell and of the hair-like spines is left as sharp as before the exodus of the sarcode."[1]

---

[1] *Monograph of Carboniferous and Permian Foraminifera*, p. 11.

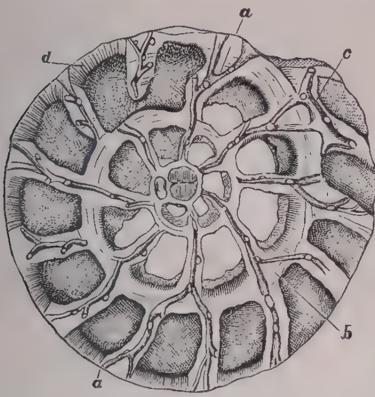

FIG. 18.—Section of *Rotalia Beccarii*, showing the canal system, *a*, *b*, *c*, in the substance of the intermediate skeleton; *d*, tubulated chamber-wall.

When a sample of the surface-layer of the "globigerina-ooze" is brought up from the sea-bottom by the sounding apparatus or the dredge, the shells are found for the most part perfect, except in the want of spines, but are of a more opaque whiteness than those captured near the surface, and hence have been supposed to be dead. This difference of aspect, however, may be attributed to the increase in the thickness of the shell by exogenous deposit, which is doubtless the cause of the like change in *Polymorphina;* and as a large proportion of these bottom-shells have their chambers filled with sarcode exactly resembling that of the types which unquestionably live at the bottom, the fact that in their young state they are found floating in the upper waters does not appear to the writer a sufficient disproof of the previously accepted belief that they live also at the bottom. And the fact that the thickened shells, when filled with their sarcodic contents, are so much heavier than sea-water as at once to sink to the bottom when placed in a vessel of that liquid seems strongly to indicate that so soon as adult growth (with successional increase in the number of chambers) has been attained, the carbonate of lime which the animal continues to separate from the sea-water is applied to the thickening of the shell, which will then sink to the bottom of the sea in virtue of its increased specific gravity. And since other *Foraminifera* undoubtedly pass their whole lives on the ocean-bottom, drawing their sustenance from sea-water in the manner already explained, there seems no reason why the subsidence of *Globigerinæ* to similar depths should put an end to their vital activity. It is only in the surface-stratum of the globigerina-ooze, however, that the shell-chambers are occupied by sarcodic bodies. Its sub-surface layer consists partly of still recognizable fragments of the shells, diffused through a mass of amorphous particles, which appears to be the product of a still further disintegration of their substance; whilst the yet deeper layers of the "ooze" consist entirely of amorphous particles, all trace of shells being lost. It was observed in various parts of the "Challenger" voyage that in particular areas the "globigerina-ooze" was altogether wanting (being replaced by a red clay, probably resulting from the metamorphosis of volcanic products), even though the living animals were found as usual in the upper waters; and the absence of this calcareous deposit on the sea-bottom seemed attributable to the pressure resulting from its very great depth—between 2500 and 3000 fathoms—which, with the aid of carbonic acid contained in all sea-water, would exert a solvent action, thus restoring to it these portions of the great calcareous deposit of which the materials had been drawn from it by the living *Globigerinæ*.

The higher forms of the Globigerine type constitute two principal series, in one of which the chambers succeed each other along a straight axis, whilst in the other they form a spire. One of the most common types of the first group is the *Textularia* (14 in fig. 1), in which the chambers are arranged bi-serially, those of the two sides alternating with each other, and each communicating with the chamber above and below it on the *opposite* side; as is well seen in the "internal cast" (fig. 17, A), which is an exact model (in glauconite or some other ferruginous silicate) of the sarcodic body that occupied the shell. The type of the second group is the almost universally diffused *Rotalia*, in which the chambers are disposed in a *turbinoid* spire (18 in fig. 1), through which passes a continuous stolon-process (as shown in the internal cast, fig. 17, B), lying on the lower and inner side. Of this type there are several very interesting modifications. Thus, in *Discorbina* (15, fig. 1) the chambers are flattened out over the surface to which the shell adheres; while in *Planorbulina* (17 in fig. 1) the early spiral plan soon gives place to the cyclical, and the shell thenceforth spreads, by concentric additions, over the surface to which it adheres. In those most-developed forms of this type which occur in warmer seas, the later-formed chambers do not merely surround the earlier, but are piled up more or less regularly upon them; and we find such aggregations spreading over the surfaces of shells, or clustering round the stems of zoophytes. Two of the most remarkable modifications of the planorbuline type, which strikingly illustrate the extremely wide range of variation among Foraminifera, are *Polytrema* and *Orbitolina.* The former, which was described by Lamarck as a coral, under the name of *Millepora rubra*, is a very common parasite upon shells and corals from the warmer seas,—sometimes spreading itself out horizontally in the form of a depressed cone, sometimes rising up from a small base in an arborescent growth, and sometimes developing itself into knobby excrescences. In all these varieties, the structure of the individual chambers, and their mode of communication with each other, remain essentially the same,—the diversity in the aggregate forms being simply due to the want of any definite plan of increase. The *Orbitolinæ* (Lamarck), which occur abundantly in certain beds of Chalk, seem to have been gigantic forms of the planorbuline type, represented at the present time by some comparatively minute organisms found on the Australian coast, which commence life as *Planorbulinæ,* and then, by the sequential addition of chambers both above and below, as well as at the margin, come to acquire a sugar-loaf or a globular form. The size of the globular examples of fossil *Orbitolinæ*, which, like the flints of chalk, are often found in Tertiary strata, varies from that of a small pea to that of a large bullet. There is a spreading *Orbitolina* in the Chalk, which sometimes attains the extraordinary diameter of *four inches.* These forms are of peculiar interest, as showing the tendency of the Foraminiferal type to that indefinite Zoophytic extension, of which we have the highest example in the *Eozoön* to be presently described.

The highest forms of the *Rotaline* type (which are confined to tropical seas) correspond with those of the "Nummuline" in the complexity of the organization of their shells, which only reveals itself to microscopic investigation. Each chamber has its own complete chamber-wall, so that the partitions which separate two contiguous chambers are double; and between these we find an additional deposit of calcareous substance, which the writer has designated as the "intermediate skeleton." This deposit is channelled-through by a set of canals distributed upon a regular plan, and altogether forming a "canal-system" (fig. 18). These do not communicate directly with the chambers, but give passage to sarcodic extensions formed by the coalescence of pseudopodia that have passed through the pores

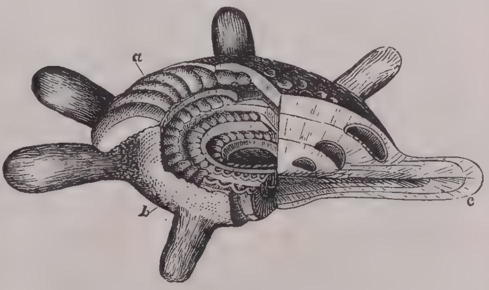

FIG. 19.—*Calcarina* laid open: *a*, tubulated wall of chambers; *b*, intermediate skeleton, extending into outgrowths; *c*, channelled by canal-system.

---

[1] Sir W. Thomson in *Voyage of the Challenger*, vol. i., p. 213.

of the proper chamber-walls. And as the development of this "canal-system" is exactly proportionate to that of the "intermediate skeleton," it may be affirmed with some confidence that, as the formation of the latter proceeds, in the first instance, from the sarcodic expansion which covers the exterior of the chamber-walls, so it is continued by the prolongation of that expansion into the "canal-system." Now, in *Calcarina* (so named from its resemblance to a spur-rowel, fig. 19) we find an extraordinary development of this intermediate skeleton,—which so completely envelops the original rotalian shell, that nothing can be seen of its chambers externally, save towards the termination of the last whorl of the spire, and which extends itself into club-shaped outgrowths that have no connection with the chambered spire except through the canal system. There is no other recent Foraminifer at present known in which the "intermediate skeleton" and the "canal-system" attain such a remarkable development; and it was under the guidance of the structure of *Calcarina*, as previously elucidated by the writer's microscopic inquiries, that Dr. Dawson was first led to recognize the "canal-system" in *Eozoön canadense*, and thus to determine its Foraminiferal character—as will be presently explained.

Another very interesting type which must be placed in the "globigerine" series on account of the coarseness of the perforations of its shell-wall, but whose spiral mode of growth differs entirely from that of ordinary Rotalians, is the *Fusulina* of the Carboniferous Limestone (fig. 20). This bears so strong a resemblance in form to the *Alveolina* of the "Milioline" series (fig. 10), that it was for a long time associated with that type, although differing from it in the opening of its chambered interior by a single fissure along the middle of the lip, instead of by a row of pores. The interior, instead of being minutely divided into a number of separate chamberlets, is found to consist essentially of a symmetrical spire of simple chambers, each of which extends on either side into an "alar prolongation," analogous to that of other spirally growing Foraminifera. But these alar prolongations, instead of overlapping the preceding whorls, as in Nummulites, are prolonged in the direction of the axis of the spire, those of each whorl projecting beyond those of the preceding, so that the shell is elongated with every addition to its diameter. These alar extensions are constricted at intervals, so as to form linear series of partially divided chamberlets, and frequently take a somewhat irregular course; so that when the shell is traversed by sections (fig. 20) these reveal an aggregation of chamberlets (like those of the investing whorls of Nummulites, fig. 24), in which no definite arrangement can at first be traced.

The Family *Nummulinida*, of which the well-known fossil *Nummulite* is a characteristic example, includes the greater part of the largest and most elaborately constructed of the "vitreous" Foraminifera. Various plans of growth prevail in this family; but its distinguishing characters consist in the completeness of the wall that surrounds each segment of the body (the partitions between the chambers being double), in the density and fine tubulation of the shell-substance, and in the presence of an "intermediate skeleton" with a "canal-system" for its nutrition. This last, however, is altogether wanting in the smallest and more feebly developed examples of the group, such as *Nonionina* (19 in fig. 1), and is scarcely traceable in the small *Polystomella crispa* (16 in fig. 1), one of the most common of British Foraminifera, though in the large *Polystomella* of tropical seas the canal-system presents a regular development not approached elsewhere. This is specially displayed by "internal casts" of this shell (fig. 21), that have been fortunately obtained by the decalcification of specimens in which the sarcodic contents of the chambers had been replaced by mineral deposit, so as to give an exact model of the original animal.

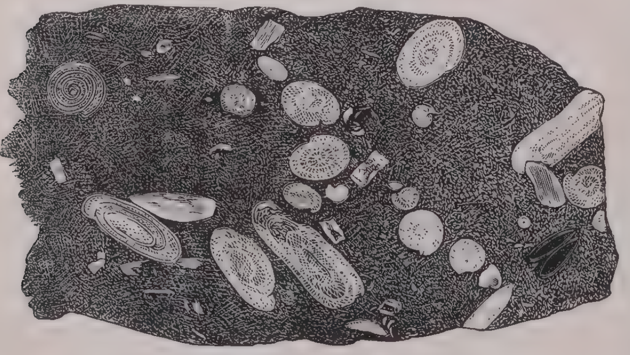

Fig. 20.—Section of *Fusulina* Limestone.

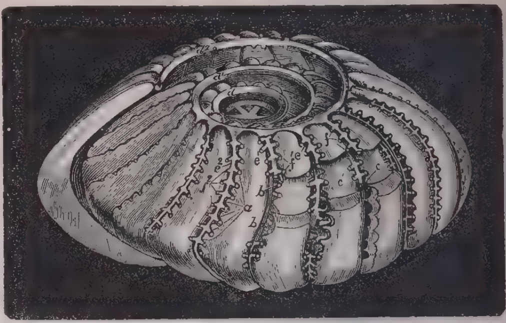

Fig. 21.—Internal cast of *Polystomella craticulata*: a, retral processes, proceeding from the posterior margin of one of the segments; b, b^1, smooth anterior margin of the same segment; c, c^1, stolons connecting successive segments and uniting themselves with the diverging branches of the meridional canals; d, d^1, d^2, three turns of one of the spiral canals; e, e^1, e^2, three of the meridional canals; f, f^1, f^2, their diverging branches.

The *Nummuline* type is most characteristically represented at the present time by the genus *Operculina*, which is so intimately related to the true Nummulite by intermediate forms that the two types cannot be separated by any definite boundaries, notwithstanding the dissimilarity of their most characteristic specimens. This genus is represented in temperate seas by small and feeble examples; but it attains a much higher development in tropical seas, the largest existing *Operculina*, however, only attaining the size of the smaller fossil *Nummulites*. As the organization of *Operculina* affords the clue, not only to that of the great Nummulitic series, which, at the commencement of the Tertiary epoch built up an immense mass of limestone that girdled a large part of the globe, but also to that of the far more ancient *Eozoön*, it will be described in some detail. The shell is a compressed nautiloid spire (fig. 22), the breadth of whose earlier convolutions increases in regular progression, but of which the last convolution (in full-grown specimens) usually flattens itself out like that of *Peneroplis* (5 in fig. 1). As a rule, the shell-wall of each whorl of the spiral completely invests all the preceding whorls; and each chamber-cavity (fig. 22, c, c) is continued from the margin towards the centre by two "alar prolongations," one on either face of the spire (c', c'), which are filled during life by extensions of the sarcodic segments that occupy the successive chambers. The size and extent of these "alar prolongations" differ much in different varieties of *Operculina*, and often in different parts of the same shell,—being, as a rule, least marked in proportion as the spire flattens itself out. There is often no external indication of them, the successive whorls of the spire being visible from the centre to the margin; but in vertical sections the spiral lamina of each whorl is still seen to be continued over the whole of the preceding whorl, even to the centre of the spire, though it may adhere to it everywhere except near its margin. The chambers are separated by double septa, which are shown in transverse section at d, d; these do not extend internally quite to the margin of the preceding whorl, but leave a fissured aperture, by which each chamber communicates with the one behind and before it, and the last chamber with the exterior, as seen at a'''. The "spiral lamina," which encloses the chambers and their "alar prolongations," is perforated by minute closely-set tubuli of about $\frac{1}{10000}$th of an inch in diameter; the orifices of these are seen on the internal wall of the chambers to be disposed with great regularity, as in fig. 23; and they seem normally to run parallel to each other (fig. 24), so as to open with equal regularity on the external surface. But in their passage from the interior towards the exterior of the shell these tubuli sometimes approach and sometimes diverge from one another, so that the pseudopodia which pass through them issue forth in closely-set bundles, separated by intervening spaces of non-tubular shell. These imperforate portions are harder than the porous shell, and often project as ridges or tubercles, forming a more or less regular "sculpturing" of the surface. They frequently correspond to the septa beneath, which are themselves composed of non-tubular shell-substance, and are overlaid by ridges of the same vitreous imperforate material. Nothing can be more inconstant, however, than this sculpturing, even on different parts of the same shell; so that it cannot be accounted as of the least value as a specific character. The outer edge of the spire is bounded by a peculiar band, of different structure from the rest, which may be distinguished as the "marginal cord" (fig. 22, *a, a*). This band, instead of being perforated by minute parallel tubuli, is traversed by a set of larger canals, inosculating with each other, and forming part of the "canal-system,"—the peculiarity of its character being clearly shown in vertical sections of well-preserved fossil Nummulites (fig. 24, *b, b*). The "canal-system" consists in the first place of a pair of "spiral canals," which run along the edges of the marginal cord, communicating with each other through its system of inosculating passages; while from each of these there pass off into spaces left between the two layers of each septum (as shown at *d′, d″*, fig. 22) a series of "interseptal canals," the distribution of which—marked out by causing them to imbibe colored fluid—is seen in the septa *e, e*. The general arrangement of this canal-system will be better understood by reference to that of *Polystomella* shown in its "internal cast" (fig. 21),—the position of the "spiral canals," however, as well as the distribution of their branches, being very different.

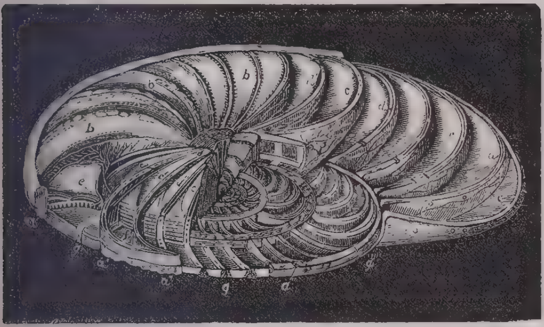

FIG. 22.—*Operculina* laid open, to show its internal structure; *a*, marginal cord seen in cross section at *a′*; *b, b*, external walls of the chambers; *c, c*, cavities of the chambers; *c′, c′*, their alar prolongations; *d, d*, septa divided at *d′, d′*, and at *d″*, so as to lay open the interseptal canals, the general distribution of which is seen in the septa *e, e*; the lines radiating from *e, e* point to the secondary pores; *g, g*, non-tubular columns.

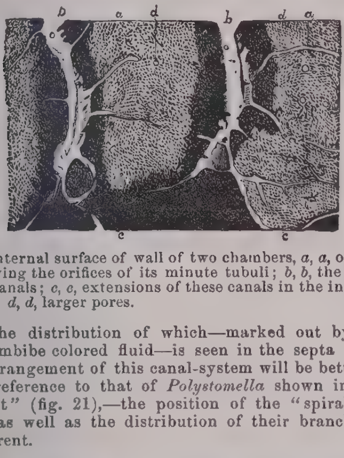

FIG. 23.—Internal surface of wall of two chambers, *a, a*, of Nummulite, showing the orifices of its minute tubuli; *b, b*, the septa containing canals; *c, c*, extensions of these canals in the intermediate skeleton; *d, d*, larger pores.

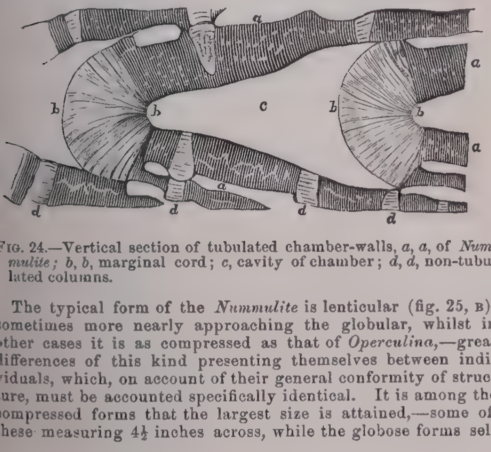

FIG. 24.—Vertical section of tubulated chamber-walls, *a, a*, of *Nummulite; b, b*, marginal cord; *c*, cavity of chamber; *d, d*, non-tubulated columns.

The typical form of the *Nummulite* is lenticular (fig. 25, B), sometimes more nearly approaching the globular, whilst in other cases it is as compressed as that of *Operculina*,—great differences of this kind presenting themselves between individuals, which, on account of their general conformity of structure, must be accounted specifically identical. It is among the compressed forms that the largest size is attained,—some of these measuring 4½ inches across, while the globose forms seldom much exceed an inch in diameter. The distinction which separates the typical *Nummulites* from the typical *Operculinæ* consists in this, that in the former the earlier whorls are completely invested by the alar prolongations of the later,—the successive turns of the spiral lamina being separated over their whole surface from those internal and external to them by intervening spaces, as shown in fig. 26, so that the spire is but little, if at all, discernible on the surface. On the other hand, we never find the later whorls of true Nummulites flattening themselves out marginally, like those of the typical Operculinæ; and there even seems reason to believe that when the spire has attained its full growth, it tends to close itself in. Curious differences are seen in the course and arrangement of the "alar prolongations;" and it has been proposed to group the numerous modifications of the Nummulitic type in accordance with these differences. Thus, in some of these, the alar prolongations extend in a regular *radial* direction from the margin to the centre of each whorl of the spire, being separated by corresponding radial prolongations of the marginal septa. In other instances, again, they follow a *sinuous* course, the septa prolonged from those of successive chambers still remaining distinct from one another. From these, again, we pass to a group in which the septa inosculate, so as to break up the alar prolongations into subdivisions, the partitions between which (as seen in fig. 26) show themselves in vertical sections in far greater numbers than the proper septa. And by a further increase of this subdivision, a complete reticulation is formed between the successive whorls of the spiral lamina, by the complex inosculation of the septal prolongations. Now, although it would not be difficult to arrange a collection of Nummulites under a number of specific types founded on these characters, if account were only taken of the specimens showing the most strongly marked differences, yet when due attention is given to the intermediate forms, they are found to present such a transitional gradation as to make it impossible to draw any absolute differential lines between the numerous components of the series.—The canal system of *Nummulina* bears a close resemblance to that of *Operculina;* and it is sometimes brought into beautiful distinctness in fossil specimens by the infiltration of ferruginous or other fossilizing material. And sometimes fragmentary "internal casts" present themselves, which admirably display the distribution of parts of the system (fig. 27).

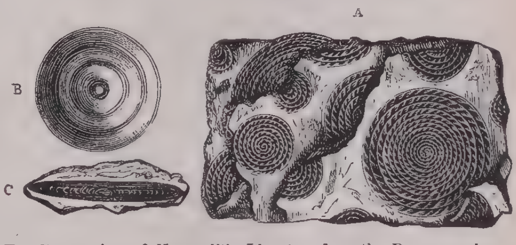

FIG. 25.—A, piece of *Nummulitic Limestone* from the Pyrenees, showing Nummulites laid open by fracture through the median plane; B, vertical section of *Nummulite;* C, *Orbitoides.*

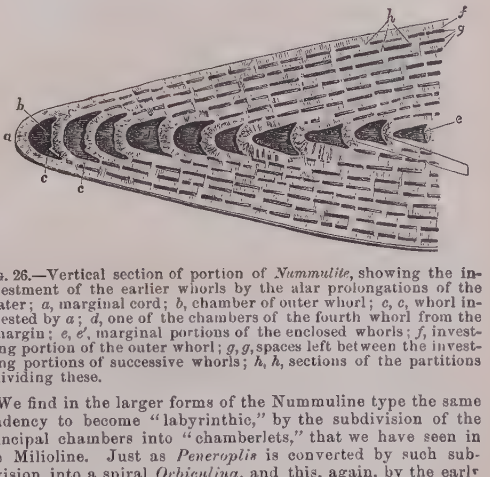

FIG. 26.—Vertical section of portion of *Nummulite*, showing the investment of the earlier whorls by the alar prolongations of the later; *a*, marginal cord; *b*, chamber of outer whorl; *c, c*, whorl invested by *a*; *d*, one of the chambers of the fourth whorl from the margin; *e, e′*, marginal portions of the enclosed whorls; *f*, investing portion of the outer whorl; *g, g*, spaces left between the investing portions of successive whorls; *h, h*, sections of the partitions dividing these.

We find in the larger forms of the Nummuline type the same tendency to become "labyrinthic," by the subdivision of the principal chambers into "chamberlets," that we have seen in the Milioline. Just as *Peneroplis* is converted by such subdivision into a spiral *Orbiculina*, and this, again, by the early exchange of the spiral for the cyclical plan of growth, into the cyclical *Orbitolite*, so *Operculina*, without any other departure from the ordinary Nummuline type, becomes *Heterostegina* (fig. 28); whilst the substitution of the cyclical for the spiral plan of growth produces the discoidal *Cycloclypeus* (fig. 29), the largest *existing* Foraminifer yet discovered, its diameter sometimes reaching 2½ inches. This is the recent representative of the very important fossil type *Orbitoides*, examples of which present themselves very abundantly in many localities in association with Nummulites (fig. 25, c), which they so closely resemble as to be easily mistaken for them. Some of them are very thin flattened disks, of the proportion shown in vertical section in fig. 30; while others have two or three times the proportionate thickness. Each disk has a central plane of chamberlets (figs. 31, 32, *b*, *b*) resembling that of *Cycloclypeus*, arranged with a general but not constant regularity in concentric circles; but whilst in the recent type this central plane is enclosed above and below by successive lamellæ of tubular shell-substance not separated from each other by any intervening spaces, the superposed lamellæ of *Orbitoides* are composed of chamberlets of irregular form (figs. 31, 32, *a*, *a*), which are piled up, one upon another, communicating vertically by minute apertures in their shell-walls. This arrangement obviously corresponds with that of the most *reticulate* forms of Nummulites. Another important link of affinity between *Orbitoides* and *Cycloclypeus* is furnished by the disposition of the canal-system, which, allowance being made for the *cyclical* plan of growth of the former, as contrasted with the *spiral* plan of the latter, is essentially the same in the two types. This, moreover, is beautifully shown in "internal casts" of *Orbitoides* found by Professor Ehrenberg in the Greensand; which, though fragmentary, display a canal-system precisely resembling that which the writer had worked out in *Cycloclypeus* by the examination of sections of the shell.

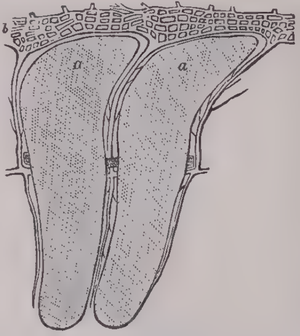

FIG. 27.—Internal cast of two chambers, *a*, *a*, of *Nummulina*, the radial canals between them passing into *b*, marginal plexus.

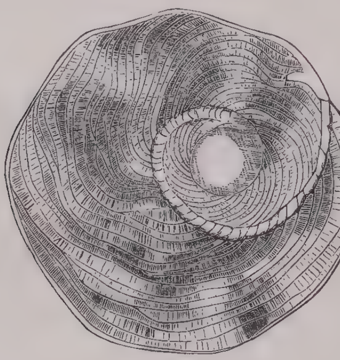

FIG. 28.—*Heterostegina.*

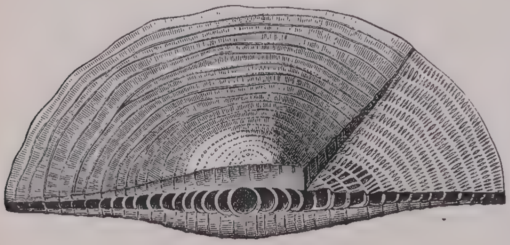

FIG. 29.—*Cycloclypeus.*

FIG. 30.—Vertical section of *Orbitoides*; *a*, primordial chamber.

It has been by the study of such "internal casts," recent and fossil, taken in connection with the microscopic appearances shown in thin sections of its calcareous layers, that the Foraminiferal nature of the Serpentine-limestone of Canada has been elucidated, of which some of the deepest beds of the *Laurentian* formation (the earliest series of stratified rocks at present known) are composed, and which has its parallel in certain beds that lie near the base of the "fundamental gneiss" of central Europe. In order that the evidence of the organic origin of this rock —a point of the highest palæontological and petrological interest—may be properly understood, regard must be had to what is even now going on in the depths of the ocean. The animals that form the enormous mass of globigerina-ooze at present in course of deposit over vast areas of the sea-bottom increase and multiply by *limited* gemmation; that is the size of each *individual* shell, which depends upon the number of segments of which it is composed, is restricted by the cessation of *continuous* gemmation after a definite number of segments has been produced. An indefinite extension of the type, however, is provided for by the detachment of further segments, which, increasing by gemmation, in their turn give origin to new shells. In the larger Foraminiferal types last described, on the other hand, *continuous* gemmation proceeds much further; and thus we may have in an *Orbitolite*, a *Nummulite*, or a *Cycloclypeus*, hundreds or even thousands of chambers, all formed by the segmental extension of the animal body from one "primordial segment." Further, in *Polytrema* we find a rotaline shell extending itself by the continuous gemmation of the animal, without any definite limit either of size or shape,—its increase taking place by *vertical* as well as by *horizontal* gemmation, so that it develops itself into forms which are essentially zoophytic. Hence there is nothing in the nature of Foraminiferal organization in the least degree inconsistent with the idea that a shell essentially "Nummuline" in its character should extend itself indefinitely by the continuous gemmation of the animal that forms it, not merely over horizontal planes, but also in the vertical direction, so as to produce solid massive structures bearing a strong general resemblance to Coral growths.

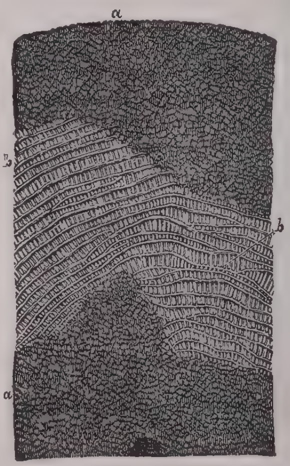

FIG. 31.—Horizontal section of disk of *Orbitoides*; showing at *b*, *b* the chamberlets of the median plane, and at *a*, *a* those of the superposed lamellæ.

Again, the dead shells of *Foraminifera* brought up from many parts of the sea-bottom are found to have their cavities filled with green or ochreous ferruginous silicates, which seem allied in composition to the "glauconite" of the Greensand formation; and these mineral deposits occupy not merely the chambers of the shell, but its canal-system also; so that when the calcareous shells have been dissolved away by dilute acid (which does not act on their contents), internal casts are obtained, which are perfect models, not only of the soft sarcodic segmented body of the animal, but also of its extensions into the canal-system that traverses the substance of the intermediate skeleton (figs. 21, 27). Yet further, this mineral deposit sometimes penetrates the minute tubuli of the shell itself; so that the surface of the internal cast of each chamber is beset with little points which represent the pseudopodia that extended themselves into those tubuli from each sarcodic segment. There can be no reasonable doubt that these "internal casts" are formed by a process of chemical "substitution,"—the animal body, in the progress of its decay, being replaced, particle by particle, by ferruginous silicates precipitated from sea-water by the liberation of ammonia. And the explanation of the fact that this replacement only occurs in particular localities (notably in the Ægean, over the Agulhas bank near the Cape of Good Hope, and on certain parts of the Australian coast) probably lies in some local peculiarity in the composition of the sea-water, which may not improbably be due to the discharge from submarine springs of water containing an unusual quantity of the materials of the deposit.

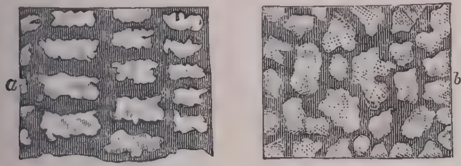

FIG. 32.—Chamberlets of the superposed lamellæ *a*, and of the median plane *b*, of *Orbitoides*, more highly magnified.

Now there is ample evidence that a similar process has taken place at various geological periods. For, as was first pointed out by Professor Ehrenberg, the *green sands* which occur in different formations from the Silurian to the Tertiary epoch (being especially characteristic of the earlier Cretaceous) consist very largely (though not exclusively) of the "internal casts" of *Foraminifera*,—as is shown by microscopic examination of their grains. Examples of such casts, which can be referred without the least difficulty to known Foraminiferal types, have been already given (figs. 17, 27). Hence there is no inherent improbability in such an occupation of the chamber-cavities, of the canal-system, and even of the minute tubulation, of a still earlier Foraminiferal structure, formed by the indefinite extension of a Nummuline growth into coral-like masses. And as there is every reason to believe that the composition of ocean-water has varied greatly at different geological periods, and especially that it contained magnesian salts at earlier epochs in much larger quantity than at present, it might be expected that the silicates which replace the soft tissues of the animals of the earliest organisms should be essentially magnesian. This expectation has been singularly confirmed by the fact ascertained by Dr. Sterry Hunt, that in certain Silurian Limestones from Wales and New Brunswick, the segments of Crinoidal stems have the soft animal tissue, which originally filled the interspaces of their calcareous network, replaced by a silicate of alumina, iron, magnesia, and potass—intermediate between glauconite and serpentine. Now, the Serpentine-limestone that lies near the base of the Laurentian formation in Canada is ordinarily composed of alternating layers of carbonate of lime (in the condition of calcite) and of silicate of magnesia (serpentine),—these layers being superposed upon one another with great general regularity (as shown in fig. 33), and frequently exceeding fifty of each kind in number. In some localities, however, the calcite is replaced by dolomite (magnesian limestone), while the serpentine is replaced either by loganite (a compound of silex, alumina, magnesia, and iron), or by some other magnesian silicate; but the alternation of calcareous and siliceous lamellæ is just as regular in these cases as in the typical ophicalcite, and there is every probability that the dolomitic layers were originally formed as calcite, and subsequently metamorphosed by magnesian infiltration. The regularity of this alternation of calcareous and siliceous lamellæ, which has no parallel in any undoubted mineral, taken in connection with the resemblance of the entire formation (extending continuously over hundreds of square miles) to ancient coral reefs, having suggested to Sir William Logan its organic origin, a careful microscopic examination of specimens that seemed to have been least altered by metamorphic action was made at his instance by Dr. Dawson of Montreal, with results that left him in no doubt either of the organic nature of the calcareous lamellæ, or of the Foraminiferal affinities of the organism. These results were confirmed by the writer of this article, whose re-examination of the subject, to meet the objections raised from time to time against Dr. Dawson's conclusions, has only had the effect of strengthening his original conviction of their truth. And the following general sketch of the structure of *Eozoön canadense* is here presented with full confidence, as expressing, not merely his own views, but those of the numerous eminent naturalists who have examined for themselves the evidentiary facts placed before them.[1]

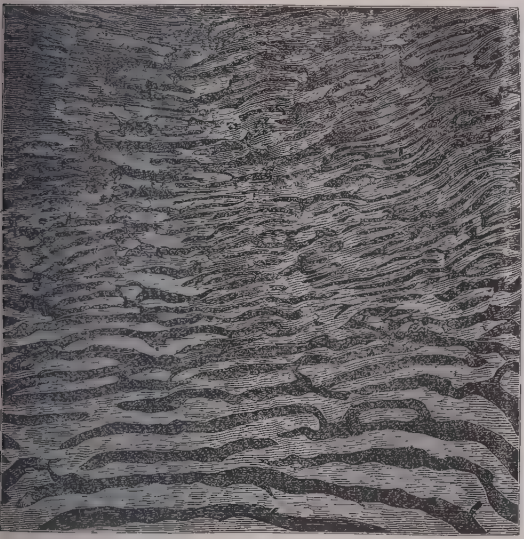

FIG. 33.—Section of the Eozoic Serpentine-limestone of Canada, showing alternation of calcareous (light) and serpentinous (dark) lamellæ.

The *calcareous* lamellæ of the Canadian Ophicalcite, which are always thickest near the base of the mass, are superposed one upon another so as to include between them a succession of "stories" of chambers (fig. 34, A^1, A^1, A^2. A^2),—the chambers of each "story" opening one into the other, as at *a*, *a*, like apartments *en suite*, but being occasionally divided by complete septa, as at *b*, *b*, which are traversed by passages of communication between the chambers they separate. Each layer of shell consists of two finely-tubulated or "Nummuline" lamellæ, B, B, which form the boundaries of the chambers above and beneath, and of an intervening deposit of homogeneous shell-substance, C, C, which constitutes the "intermediate skeleton." The amount of this varies considerably in different layers, while the thickness of the "proper wall" of the chambers (or "Nummuline lamella") remains almost constant, the distinction between the two being just as marked (in well-preserved specimens) as it is in the recent *Calcarina* (fig. 19). The tubuli of the "Nummuline" lamellæ are usually filled up (as in the Nummulites of Nummulitic Limestone) by mineral infiltration, so as to present only a fibrous appearance in thin transparent sections; but it fortunately happens that, through its having escaped such infiltration, the tubulation (fig. 35, *a*, *a*) is occasionally as distinct as it is in recent Nummuline shells, bearing a strong resemblance in its occasional waviness (as at *a′ a′*) to that of a crab's claw. The "intermediate skeleton," whenever it forms a thick layer, is penetrated by arborescent systems of canals (fig. 34, E, E), which are often distributed so extensively and so minutely through its substance as to leave very little of it without a branch. These canals (fig. 35, *b*, *b*) take their origin, not directly from the chambers, but from irregular *lacunæ* or interspaces between the outside of the proper chamber-walls and the "intermediate skeleton," exactly as in *Calcarina*,—the extensions of the sarcode body which occupied them having apparently been formed by the coalescence of the pseudopodial filaments which had issued forth through the tubulated lamellæ. It is to be remarked that the substance, not merely of the intermediate skeleton, but of the Nummuline layer, is traversed by oblique lines, indicating the cleavage-planes of calcite. This is what is constantly seen in fossilized calcareous organisms—

---

[1] Of those who may be considered as qualified by special study of the *Foraminifera* to form a judgment on this matter, Mr. H. Carter is the only one who has expressed his dissent; and he has never seen the most characteristic specimens of *Eozoic* structure. On the other hand, the late Professor Max Schultze, who took up the inquiry towards the end of his life, not only publicly and most explicitly expressed his conviction that the canal-system found in the calcareous lamellæ *must* be organic, but left behind him an elaborate Memoir on the subject, with ample illustrations, which unfortunately still remains unpublished.

such as the shells and spines of *Echinida*, or the stems of *Crinoidea*—which retain their organic arrangement unchanged, and thus affords no basis whatever for the contention that these calcareous layers are purely mineral. On the other hand, the fact that the portions of the canal-system, shown in thin sections (fig. 35), continually *cross* the cleavage planes, instead of lying between them, furnishes a strong objection to the hypothesis that the appearances which have been interpreted as indicating a regular distribution of ramifying canals can have been produced by mineral infiltration. Further, the distinct continuity of these cleavage-lines through the "Nummuline layer" (fig. 35, *a*, *a*) proves this layer to be essentially *calcareous*,—the layer of serpentine-fibres which is commonly found in its place after decalcification being a secondary deposit, formed in the manner to be presently described.

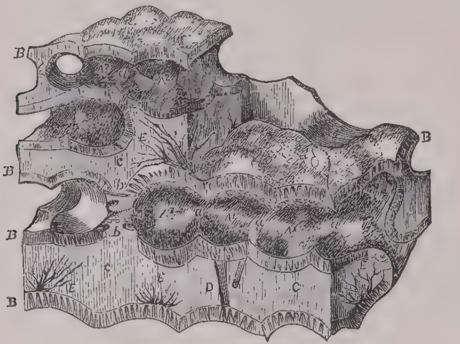

FIG. 34.—Calcareous skeleton of *Eozoön canadense:* A^1, A^1, chambers of lower story; A^2, A^2, chambers of upper story, imperfectly divided at *a*, *a*; B, B, tubulated or Nummuline layers; *c*, *c*, intermediate skeleton; D, large passage from one story to another; E, E, E, branching canal-systems.

When a well-preserved fragment of *Eozoön* has been treated with dilute acid, so as to dissolve away the calcareous lamellæ, we have an "internal cast" in serpentine, which gives us a precise model of the sarcodic body by which the cavities of the calcareous structure were originally occupied. We see, in the first place (fig. 36), that each of the layers of serpentine forming the lower part of such a specimen shows more or less of a segmental arrangement,—being, in fact, made up by the coalescence of a number of minute serpentinous granules, such as are shown separately or but slightly coalescing in the upper part of the figure. This shows that there is not that difference between the regularly "lamellated" and the "acervuline" plans of growth which might at first sight be supposed,—the chambers having been separate in the latter, whilst in the former they constituted imperfectly subdivided galleries. In those wider spaces between the serpentine-layers, which were originally occupied by the thicker calcareous layers forming the "intermediate skeleton," we find internal casts of the branching canal-system; and the development of this system is found, as in recent Foraminifera, to bear a constant relation to the amount of the secondary calcareous deposit. But further, in specimens in which the "Nummuline" layer was originally well preserved, and in which the decalcifying process has been carefully managed, that layer is represented by a thin white film covering the exposed surfaces of the segments; as is shown superficially over the upper part of fig. 36, and in section, along the margins of the serpentine-layers, in the lower. When this film is examined with a sufficient magnifying power, it is found to consist of extremely minute needle-like fibres of serpentine; which sometimes stand upright, parallel, and almost in contact with one another, like the fibres of asbestos, but which are frequently grouped in converging brush-like bundles, so as to be very close to each other in certain spots at the surface of the film, whilst widely separated in others,—thus indicating exactly the same irregularities in the grouping of the tubuli that (as already mentioned) we find in recent Nummulines. And it is not unfrequently seen that where bundles of these fibres converge towards the surface, so that the pseudopodial threads they represent would have issued forth in clusters, the internal casts of the canal-system take their origin in such aggregations. We have here, in fact, in this most ancient of all fossils at present known, the most complete model we possess of any extinct animal, extending even to its soft sarcodic threads of less than $\frac{1}{10000}$th of an inch in diameter,—this model being conformable in all essential particulars to the "internal casts" of existing *Foraminifera* which are at present in course of production on the sea-bottom.

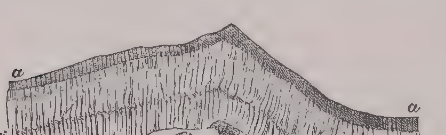

FIG. 35.—Highly-magnified section of a portion of the calcareous skeleton of *Eozoön canadense; a*, *a*, Nummuline layer showing parallel tubuli with a wavy bend along the plane *a'*, *a'*; *b*, origins of canal-system penetrating the intermediate skeleton *c*, *c*, which is traversed obliquely by cleavage planes that pass on into the Nummuline layer.

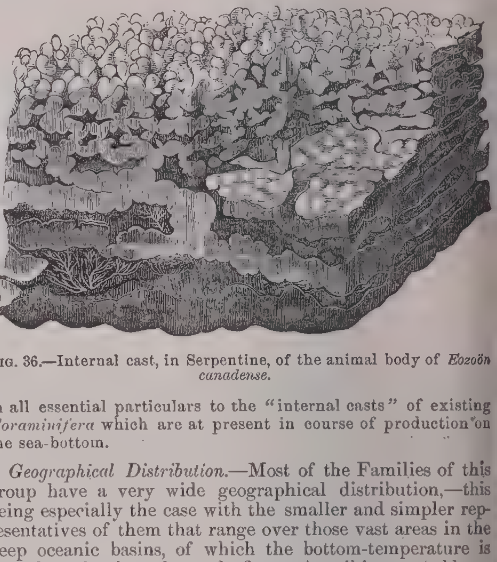

FIG. 36.—Internal cast, in Serpentine, of the animal body of *Eozoön canadense.*

Geographical Distribution.—Most of the Families of this group have a very wide geographical distribution,—this being especially the case with the smaller and simpler representatives of them that range over those vast areas in the deep oceanic basins, of which the bottom-temperature is kept down by the polar underflow. A striking resemblance has long been noted between the poor and feeble Foraminiferal fauna of shallow waters in colder temperate seas, and that of great depths in tropical seas; and this similarity is now explained by the correspondence of the temperature to which these two faunæ are subjected. The larger and most developed examples of existing *Foraminifera*, on the other hand, are limited to the shallower seas near tropical shores, or covering coral reefs where the bottom-temperature is comparatively high; or to partially enclosed seas, like the Mediterranean and Red Sea, which are cut off from the polar underflow by the shallowness of the straits which connect them with the oceanic basin. It is in such seas that we meet with the largest *Orbiculinæ*, and the most complex *Orbitolites* and *Alveolinæ*,—the first of these "imperforate" types being generally abundant in tropical shore-sands, the second in shallow dredgings along the Australian coast, the great barrier-reef, and the lagoons of "atolls" in the Coral Sea, while the third seems to attain its highest development in the Philippine Seas. So, again, among the "perforate" *Lagenida*, we find the "nodosarian" and "cristellarian" types attaining a very high development in the Mediterranean; the most complex forms of the "rotalian" type, including the zoophytic *Polytrema*, are only met with in tropical or sub-tropical seas; while, with the exception of small and modified *Polystomellæ* and dwarfed *Operculinæ*, there are no known representatives in the colder-temperate or polar seas either of the gigantic *Cycloclypeus*, or of the large *Operculina* and *Heterostegina* of the tropics. But while the Foraminiferal fauna thus obviously depends on an elevated temperature for the attainment of its highest development as regards the size and complexity of its individual members, the numerical multiplication of its lower forms (as is the case in many other groups) seems to be favored by a much lower degree of warmth; so that we find the vast area of "globigerina-ooze" extending to the borders of the Polar seas. There, however, it ceases almost abruptly, the place of this calcareous deposit being taken by an accumulation of the siliceous skeletons of Radiolarians and Diatomaceæ.

It is not a little curious, however, that recent researches should have disclosed the fact, that the existing Arenaceous *Lituolida* attain their highest development—in regard no less to size and complexity of structure than to number—on the *deep* sea-bottom,—the additions to our previous knowledge of the Foraminiferal fauna made by the dredgings of the "Porcupine," the "Valorous," and the "Challenger" having been far greater in this section than in either of the calcareous-shelled groups. And it would hence appear that an elevated temperature is not as essential to the high development of the *Foraminifera* which construct "tests" by gluing together grains of sand, as it is to that of the shell-forming types which separate the material of their "porcellanous" or "vitreous" skeletons from the sea-water in which they live.

Geological Distribution.—There is no division of the Animal Kingdom whose range in time (so far as is at present known)[1] can be compared with that of the *Foraminifera.* Looking, indeed, to the vast series of ages that must have been required for the deposit of that long succession of Upper Laurentian and Huronian rocks which intervenes between the Eozoic Limestone of the Lower Laurentians of Canada, and the lowest strata in which the most ancient representatives of the Palæozoic fauna have as yet been found, it may even be said that all other fossils are modern by comparison. For the interval between the formation of the Canadian *Eozoön* and the period represented by the oldest fossils of the Lower Cambrian series seems undoubtedly to have been quite as great—geologically speaking—as that which intervened between the latter and the existing epoch, if not greater,—the "fundamental gneiss" of Sir Roderick Murchison, which represents in central Europe the Laurentians of Canada and near the base of which is found the kindred *Eozoön bavaricum,* having a thickness estimated at 90,000 feet, and being overlaid by a great thickness of other non-fossiliferous rocks. Hence the determination of the organic origin of this Ophicalcite, and of its Foraminiferal affinities which has been effected by the examination and comparison of parts of specimens so minute as to be scarcely visible to the naked eye, must be considered as one of the most remarkable results of microscopic research—fully equal in importance, when considered in all its bearings, to the discovery by Prof. Ehrenberg of the Foraminiferal origin of Chalk.[2]

Indications of Eozoic structure have been found in various strata of uncertain age underlying the Silurians of North America, and also in some of the older rocks of the Scandinavian series; and there is no improbability in the idea that its existence may have been prolonged through the whole of that long period, commonly regarded as azoic, which has been designated by Prof. Dana as *Archæan.* In the earliest strata usually accounted fossiliferous there are found, alike in the old and new continents, a number of curious organisms, sometimes of considerable size, which have received the names *Archæocyathus, Stromatopora,* and *Receptaculites.* The nature of these is still problematical, their internal structure not having yet been fully elucidated; but while it seems probable, on the one hand, that among the organisms whose similarity of external conformation has led to their association under these names, there may be several types of structure essentially different, there seems considerable reason to believe that some among them are really gigantic *Foraminifera,* presenting approximations to calcareous Sponges. The Limestones of the Silurian period have not been as yet minutely searched for the smaller forms of *Foraminifera;* but green sands of Silurian age occur in various localities, the grains of which can be identified as "internal casts" of Foraminiferal shells.

It is in the Carboniferous Limestone that we first recognize a varied and abundant Foraminiferal fauna, which has recently been made the subject of special study by Mr. H. B. Brady,[3] whose very interesting results may be summed up as follows. (1) Of the "imperforate" or "porcellanous" *Foraminifera* no examples have been detected. (2) Of the "perforate" or "vitreous" series, on the other hand, each principal group is represented: the *Lagenida* very slightly; the *Globigerinida* by *Textularia* and various *Rotalian* types; while of the *Nummulinida* we find, not only three generic forms that are at the same time individually small and scantily diffused, but (in certain localities) such an accumulation of comparatively large shells of *Fusulina* (fig. 20), that they constitute almost the sole material of calcareous beds extending over large areas. (3) A large proportion of the Foraminiferal types of this period belong to that "arenaceous" group which at present contains not merely the *Lituolida,* whose "tests" are entirely made up of cemented sand-grains (among which the *Saccammina,* fig. 5, *a, b,* is distinctly recognizable), but also a number of generic types more or less allied to the recent *Valvulina,* in which there is a "vitreous" shelly basis, more or less thickly incrusted by an arenaceous envelope. The "isomorphism" of these with true "nodosarines" and "rotalines" suggests the question whether they are not really in an evolutionary stage between the true sandy-tested and the completely calcareous-shelled types.

But there is a larger question even than this,—namely, whether those massive beds of Carboniferous Limestone whose texture is sub-crystalline, and in which scarcely any traces of organic structure are now discernible, do not owe their origin, like analogous beds of the Cretaceous formation, to Foraminiferal life. The general tendency of recent geological opinion has been to account for the absence of all traces of organic structure in such beds by the "metamorphism" they have undergone subsequently to their original deposition. Of the completeness with which such metamorphism may obliterate the evidence of organic origin in calcareous rocks it is impossible to have more "pregnant instances" than those afforded by the purely crystalline marble of Carrara, which is unquestionably a metamorphic Oolite, and the crystalline conversion of the Antrim Chalk in the neighborhood of the basaltic outburst which forms the Giant's Causeway. The abundance of Corals, however, in various beds of Carboniferous Limestone, accompanied by such accumulations of Brachiopods, Crinoids, etc., as might have been associated with them on coral reefs, taken in connection with the fact that the substance of existing reef-building corals, when raised by upheaval, sometimes exhibits a metamorphism that causes it to bear a close resemblance to carboniferous limestone, has seemed to favor the belief that the azoic sub-crystalline beds of that formation had their origin in Coral growths. Against this, however, it may be urged that we have at the present time no *continuity* of Coral growth over areas that are at all comparable to those which we find continuously covered with Carboniferous Limestone; that the real parallel to these is presented by the continuous beds of Chalk formerly deposited over vast marine areas, by those of the Nummulitic Limestone of the succeeding period, and by those of Globigerina-ooze still in progress of production; and that, if the tropical sea-bottom were now elevated into dry land, we should find over the deeper areas a continuous Foraminiferal deposit, interrupted in particular localities by upheaved reefs of Coral, whose slopes would be covered with calcareous-shelled Mollusks, Echinoderms, etc., bearing a general correspondence with the great Carboniferous Limestone formation.

Moreover, it has now come to be generally admitted that "metamorphism" is connected with mechanical disturbance, and especially with that "lateral thrust" which is the principal source of the plication and contortion of strata, and which must have given rise to the evolution of great heat. That such a change was extensively produced in the Carboniferous rocks of Great Britain at the end of the Palæozoic period, when the horizontal and continuous Coal-measures were thus broken up into separate "basins," bordered by intervening ridges formed by the uplifting of their subjacent limestone, is universally recognized. But, on the other hand, over the vast area of Russia that lies between the Baltic and the Ural mountains, there seems to have been no such force in action. Its strata are so nearly level that the determination of their order of superposition has been difficult. And there is such a remarkable absence of metamorphism even in those of Silurian age that we there find what are elsewhere *slates* represented by beds of *clay*, constituting the original form of that deposit which has elsewhere acquired the slaty character by subsequent metamorphism. Now, since it is here that we also find the most extensive development of *Fusulina*-limestone in the place of those sub-crystalline beds which elsewhere form the great bulk of the Carboniferous Limestone, there seems exactly the same reason for regarding such a Foraminiferal deposit as the original form of those beds. And this view derives remarkable confirmation from the phenomena presented by the Carboniferous Limestone of Ireland, which has been recently studied with great care by Prof. Hull.[1] This formation extends over a very considerable area of the island, —constituting in its central portion an elevated plateau, whose nearly horizontal strata present no indication of lateral thrust, whilst along the margin of this area the calcareous strata have been elevated into ridges by thrust from the outside, with more or less of plication and contortion. Now, in these marginal ridges the traces of organic origin are scanty,—the presence of fossils, whether large or minute, being the exception and not the rule. In the level strata of the central plateau, on the other hand, the evidence of organic origin is almost everywhere complete; and whilst fossil Corals, Mollusks, Crinoids, etc., are abundant in particular beds, great masses of the limestone are found by microscopic examination to consist of little else than minute Foraminiferal shells. A very strong case, then, seems made out for the belief that Foraminiferal life has contributed very largely to the production of those vast beds of Carboniferous Limestone (often exceeding 1500 feet in thickness) in which scarcely any trace of organic origin can now be found,—this share bearing to that of the Corals, which are generally credited with the whole, somewhat of the same proportion that the Foraminiferal ooze of the deep-sea bottom at the present time does to the Coral reefs of shallow waters, and the shells of Mollusks and Echinidans that live among them.

---

[1] Appearances resembling Annelid burrows have been found in Laurentian rocks; but these cannot be safely relied on as evidence of the existence of Marine Worms at that epoch.

[2] "The discovery of organic remains in the crystalline limestones of the ancient gneiss of Canada," says Prof. Gümbel, the accomplished director of the Geological Survey of Bavaria, "for which we are indebted to the researches of Sir William Logan and his colleagues, and to the careful microscopic investigations of Drs. Dawson and Carpenter, *must be regarded as opening a new era in geological science.*"

[3] *Monograph of the Carboniferous and Permian Foraminifera,* published by the Palæontographical Society, 1876.

In the earlier Secondary rocks we do not find by any means the same evidence of abundant Foraminiferal life; but this is very probably to be accounted for by the conditions of their deposition. For during the Triassic period we find no representative of a deep oceanic calcareous deposit,—the only considerable limestone bed (the muschelkalk) being obviously composed of the remains of the more developed fauna of comparatively shallow water. It is interesting, however, to find certain clay beds of the New Red Sandstone yielding *Foraminifera*, chiefly of the Cristellarian type; which can be identified—not only generically and specifically, but even varietally—with forms common in the Italian Tertiaries, and still living in the Mediterranean. In many of the Liassic clays *Foraminifera* are found in great abundance; and here the "porcellanous" group first characteristically shows itself under one of its least modified types, the *Spiroloculina*. In the formation of many Oolitic Limestones it seems probable that *Foraminifera* had a considerable share. For while the material of many of the calcareous beds belonging to this formation was obviously furnished by débris of Coral, Echinoderms, and Mollusks, the nuclei of the component grains of the true *Oolitic* beds are so often found to be minute *Foraminifera*, that we seem justified in regarding those beds as having been formed by a sub-aërial metamorphosis of shore-sands largely composed of the minute shells belonging to that group, like many tropical shore-sands of the present time.

It was by the comparative study of specimens of Chalk brought from different localities that Professor Ehrenberg was first led to the conclusion[2] that this vast formation was mainly produced by the progressive accumulation and subsequent disintegration of the minute shells of various types of *Foraminifera*, especially *Globigerina* (fig. 14),—a conclusion to which Professor W. C. Williamson was independently led by his study of the "Levant mud," a white chalk-like deposit at present in progress of formation on the comparatively shallow bottom of the eastern end of the Mediterranean.[3] This conclusion has been fully borne out by the deep-sea soundings and dredgings since carried on; which have established the fact that large areas of the great ocean-basins are covered to an unknown thickness by a Foraminiferal ooze, which, when dried corresponds in every particular with ordinary Chalk. And there is, moreover, very strong evidence that this deposit is not a repetition of the old Chalk formation, but an actual *continuation* of it over areas which have undergone no such upheaval as that which raised the chalk of Europe, Asia, and America into dry land. Not only the Chalk, but the subjacent Greensand appears to have originated in great degree in Foraminiferal life,—its glauconite grains being (in the localities in which they seem to have undergone least attrition) internal casts of easily-recognizable types of that group, formed by the process already described as still going on upon parts of the existing sea-bottom. Various larger types of all the principal groups of *Foraminifera* occur in different parts of the Cretaceous formation,—the "porcellanous" sub-order being now fully represented.

The highest development of the Foraminiferal type, as measured by the extraordinary abundance of its largest and most complex examples, seems to have been attained in the early Tertiary period, to which belongs the vast formation of Nummulitic Limestone, forming a band often of 1800 miles in breadth, and sometimes attaining several thousand feet in thickness, which may be traced eastwards from the Atlantic shores of Southern Europe and Northern Africa (the Pyramids being built of this rock, and on a terrace formed by it) through Western Asia to Northern India and China, and likewise over large areas in North America—thus taking, to use the words of Sir Charles Lyell, a far more conspicuous part than any other Tertiary group in the solid framework of the earth's crust. In some localities it seems to lie conformably upon Cretaceous strata, so as to establish the continuity between the latest Secondary deposits and the earliest Tertiaries formed in the deep sea. In some localities this Limestone is essentially composed of an aggregation of *Nummulites* (including, however, the fossil remains of higher organisms), the spaces between the large and entire shells being filled in by minuter forms and by the débris of previous generations of the larger; whilst in other localities the *Nummulites* are replaced, wholly or in part, by *Orbitoides* and *Orbitolites*. In the Paris basin the Nummulitic Limestone is represented by the *Calcaire grossier*, which is for the most part of Foraminiferal origin. Its lower calcareous beds are chiefly Nummulitic; but in the middle part of the series we find the *Miliotine* group predominating, some of its beds being chiefly composed of *Orbitolites*, whilst others (notably those of which a large

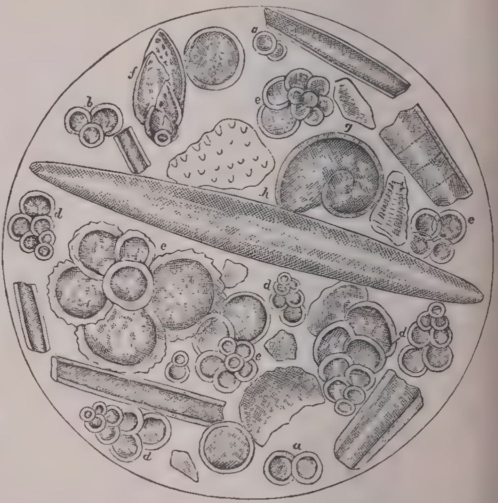

Fig. 37.—Microscopic Organisms in Chalk from Gravesend: *a, b, c, d. Textularia globulosa; e, e, e, e, Rotalia aspera; f, Textularia aculeata; g, Planularia hexas; h, Navicula.*

[3] *Memoirs of the Manchester Philosophical Society*, vol. viii.

part of Paris is built) are essentially made up by the aggregation of the smaller *Miliolæ*. The calcareous sand of Grignon, which consists in great part (like many beds of the Oolitic formation) of shells comminuted by the action of the waves, contains a great abundance of *Foraminifera*,—among them the large and complex *Dactylopora*, which is only represented at the present time by a minute form of extreme simplicity. In various marine deposits of the middle and later Tertiary periods, especially those which form the slopes of the Apennines, *Foraminifera* are abundant; but the larger forms gradually give place to the smaller, and the Foraminifera fauna progressively approximates more closely to that of the present time.

Altogether it would certainly be not too much to affirm that so far as we are justified by positive evidence, no single group of the Animal Kingdom has contributed, or is at present contributing, so largely as the one of which a sketch has now been given to the formation of the crust of the earth,—by separating carbonate of lime from its solution in sea-water, and thus restoring to the solid form the vast quantity of that material which is continually being taken up in solution, and discharged into the oceanic basin, by the percolation of rain-water through the calcareous strata which have been elevated into dry land, which are thus undergoing continual degradation. And if the origin of the great part of the Carboniferous Limestone in Foraminiferal rather than in Coral life be accepted as probable, the share taken by Foraminiferal life in this process during the Palæozoic period would appear to have been fully equalled by that which it took in the formation of the Chalk, and in the production of the Nummulitic Limestone, of more modern geological epochs. (W. B. C.)

FORBACH, a town of Lorraine, Germany, the chief town of a circle, is situated on an affluent of the Rossel and on the Metz and Saarbrücken Railway, about 5½ miles southwest of Saarbrücken. Its industries include brewing, tanning, and the manufacture of glass, soap, and pasteboard. At a short distance from the town are the large iron-works of De Wendel, Enkel & Company, which employ about 1500 workmen. There are also large coal mines in the vicinity. Forbach possesses a real school, a higher female school, a Catholic and two Protestant churches, and a synagogue. After the battle on the neighboring heights of Spicheren, August 6, 1870, in which the French under General Frossard were defeated by the Germans under Prince Frederick Charles, the town was occupied by the German troops, and at the conclusion of the war it was annexed to Germany. The population in 1875 was 6178.

FORBES, ALEXANDER PENROSE (1817–1875), bishop of Brechin, was born at Edinburgh, June 6, 1817. He was the second son of Lord Medwyn, a judge of the Court of Session, and grandson of Sir William Forbes of Pitsligo. He studied first at the Edinburgh Academy, then for two years under the Rev. Thomas Dale, the poet in Kent, passed one session at Glasgow university, and, having chosen the career of the Indian civil service, completed his studies at Haileybury College. In 1836, he went to Madras, but in consequence of ill-health, the result of the climate, he was obliged after two or three years to return to England. He then entered Brasenose College, Oxford, where in 1841 he obtained the Boden Sanskrit scholarship, and in 1844 took his degree of B.A. He was at Oxford during the early years of the great religious movement known for some time as Puseyism, and he was powerfully influenced by association with its leaders, Newman, Pusey, and Keble, and entered heartily into their views and aims. In 1844 he was ordained deacon and priest in the English Church, and held an English curacy; but being naturally attracted to the Episcopal Church of his native land, then recovering from long depression, he removed in 1846 to Stonehaven, the chief town of Kincardineshire. The same year, however, he was appointed to the vicarage of St. Saviour's, Leeds, and co-operated in a mission formed there, with strong Romanizing tendencies, which ere long collapsed. In 1847 Forbes was called to succeed Bishop Moir in the see of Brechin. He removed the episcopal residence to Dundee, where he resided till his death, combining the pastoral charge of the congregation with the duties of the see. He labored in season and out of season, never sparing himself when work was to be done, and won not only golden opinions but warm affections, especially among the working classes. Through his energy and devoted endeavors several new churches were built in Dundee, and among them the pro-cathedral of St. Paul's. He was once prosecuted in the church courts for heresy; the accusation being founded on his primary charge, delivered and published in 1857, in which he set forth his views on the eucharist. He made a powerful defence of the charge, and was acquitted with "a censure and an admonition." Keble wrote in his defence, and was present at his trial at Edinburgh. Forbes was a good scholar, and above all a scientific theologian, and his social qualities were such as to endear him to all who knew him. He was author of treatises on the Nicene Creed and the Thirty-nine Articles, various commentaries and devotional works, discourses, and reviews. He died at Dundee, October 8, 1875.

FORBES, DAVID (1828–1876), F.R.S., an accomplished traveller, mineralogist, metallurgist, chemist, and writer on chemical geology, brother of Professor Edward Forbes, was born at Douglas, Isle of Man, and received his early education there and at Brentwood in Essex. When a boy he manifested "an enthusiastic disposition as regards science," and at the age of fourteen had already acquired a remarkable knowledge of chemistry. This subject he studied at the university of Edinburgh, and he was still young when he was appointed superintendent of the mining and metallurgical works at Espedal in Norway. Subsequently he became a partner in the firm of Evans & Aiken, nickel-smelters, of Birmingham, and in that capacity visited Chili, Bolivia, and Peru. He died in London, December 5, 1876. Micro-petrology and chemical geology owe much to the researches of David Forbes. Besides reports for the Iron and Steel Institute, of which, during the last years of his life, he was foreign secretary, he wrote upwards of 50 papers on scientific subjects, among which are the following:—"The Action of Sulphurets on Metallic Silicates at High Temperatures," *Rep. Brit. Assoc.*, 1855, pt. ii. p. 62; "The Relations of the Silurian and Metamorphic Rocks of the south of Norway," *Ib.*, p. 82; "The Causes producing Foliation in Rocks," *Journ. Geol. Soc.*, xi., 1855; "The Chemical Composition of the Silurian and Cambrian Limestones," *Phil. Mag.*, xiii. pp. 365–373, 1857; "The Geology of Bolivia and Southern Peru," *Journ. Geol. Soc.* xvii. pp. 7–62, 1861.

FORBES, DUNCAN (1685–1747), of Culloden, was born at Bunchrew or at Culloden near Inverness on the 10th of November, 1685. After he had completed his studies at the universities of Edinburgh and Leyden, he was admitted advocate at the Scottish bar in 1709. His own talents and the influence of the Argyll family secured his rapid advancement, which was still further helped by his loyalty to the Hanoverian cause at the period of the rebellion in 1715. In 1722 Forbes was returned member for Inverness, and in 1725 he succeeded Dundas of Arniston as lord advocate. He inherited the patrimonial estates on the death of his brother in 1734, and in 1737 he attained to the highest legal honors in Scotland, being made lord president of the Court of Session. As lord advocate, he had labored to improve the legislation and revenue of the country, to extend trade and encourage manufactures, and no less to render the Government popular and respected in Scotland. In the proceedings which followed the memorable Porteous mob, for example, when the Government brought in a bill for disgracing the lord provost of Edinburgh, for fining the corporation, and for abolishing the town-guard and city-gate, Forbes both spoke and voted against the measure as an unwarranted outrage on the national feeling. As lord president also he carried out some useful legal reforms; and his term of office was characterized by quick and impartial administration of the law. The rebellion of 1745 found him at his post, and it tried all his patriotism. For some years before, he had repeatedly and earnestly urged upon the Government the expediency of embodying Highland regiments, putting them under the command of colonels whose loyalty could be relied upon, but officering them with the native chieftains and cadets of old families in the north. "If Government," said he, "pre-engages the Highlanders in the manner I propose, they will not only serve well against the enemy abroad, but will be hostages for the good behavior of their relations at home; and I am persuaded that it will be absolutely impossible to raise a rebellion in the Highlands." Such a plan was afterwards successfully pursued by Chatham; but, though Walpole is said to have approved of the scheme, it was not adopted by the council. On the first rumor of the Jacobite rising Forbes hastened to Inverness, and through his personal influence with the chiefs of Macdonald and Macleod, those two powerful western clans were prevented from taking the field for Charles Edward; the town itself also he kept loyal and well protected at the commencement of the struggle, and many of the neighboring proprietors were won over by his persuasions. His correspondence with Lord Lovat, published in the Culloden papers, affords a fine illustration of his character, in which the firmness of loyal principle and duty is found blended with neighborly kindness and consideration. But at this critical juncture of affairs, the apathy of the Government interfered considerably with the success of his negotiations. Advances of arms and money arrived too late, and though Forbes employed all his own means and what money he could borrow on his personal security, his resources were quite inadequate to the emergency. It is doubtful whether these advances were ever fully repaid. Part was doled out to him, after repeated solicitations that his credit might be maintained in the country; but it is evident he had fallen into disgrace in consequence of his humane exertions to mitigate the impolitic severities inflicted upon his countrymen after their disastrous defeat at Culloden. The ingratitude of the Government, and the many distressing circumstances connected with the insurrection, sunk deep into the mind of Forbes. He never fairly rallied from the depression thus caused, and after a period of declining health he died on the 10th of December, 1747, in the sixty-second year of his age.

Forbes was a patriot without ostentation or pretence, a true Scotsman with no narrow prejudice, an accomplished and even erudite scholar without pedantry, a man of genuine piety without asceticism or intolerance. His country long felt his influence through her reviving arts and institutions; and the example of such a character in that coarse and venal age, and among a people distracted by faction, political strife, and national antipathies, while it was invaluable to his contemporaries in a man of high position, is entitled to the lasting gratitude and veneration of his countrymen. In his intervals of leisure he cultivated with some success the study of philosophy, theology, and biblical criticism. He is said to have been a diligent reader of the Hebrew Bible. His published writings, some of them of importance, include—*A Letter to a Bishop, concerning some Important Discoveries in Philosophy and Theology* (1732); *Some Thoughts concerning Religion, natural and revealed, and the Manner of Understanding Revelation* (1735); and *Reflections on Incredulity* (2d ed. 1750). His correspondence was collected and published in 1815, and a memoir of him (from the family papers) was written by Mr. Hill Burton, and published along with a *Life of Lord Lovat*, in 1847. His statue by Roubiliac stands in the Parliament House, Edinburgh.

FORBES, Edward (1815–54), F.R.S., a celebrated naturalist, was born at Douglas, in the Isle of Man, February 12, 1815. While still a child, when not engaged in reading, or in the writing of verses and drawing of caricatures—ever favorite recreations with him—he occupied himself with the collecting and arranging of insects, shells, minerals, fossils, specimens of plants, and other natural history objects. From his fifth to his eleventh year, delicacy of health precluded his attendance at any school, but in 1828 he became a day scholar at Athole House Academy in Douglas, where he was universally beloved by his companions, and was recognized by his master as an apt if not a good scholar. In June, 1831, he left the Isle of Man for London, where during four months he studied drawing under Mr. Sass, a well-known artist. In October, however, having given up all idea of making painting his profession, he returned home; and in the following month he matriculated as a student of medicine in the university of Edinburgh. During his first winter session there he attended lectures on anatomy, theoretical chemistry, and materia medica; and in the ensuing summer session botany, natural history, and practical chemistry claimed his attention. His vacation in 1832 he spent in diligent work on the natural history of the Isle of Man. In 1833 he made a tour in Norway, the botanical results of which were published in Loudon's *Magazine of Natural History* for 1835–36. In the summer of 1834 he visited the Isle of Man and Wales, and devoted much time to dredging in the Irish Sea; and in the succeeding year he travelled in France, Switzerland, and Germany. Born a naturalist, and having no relish for the practical duties of the surgeon or physician, Forbes was no zealous student of medicine, and he finally in the spring of 1836 abandoned the idea of taking a medical degree, resolving to devote himself to science and literature. The winter of 1836–37 found him at Paris, where he attended the lectures at the Jardin des Plantes on natural history, comparative anatomy, geology, and mineralogy. Leaving Paris in April, 1837, he repaired to the south of France, whence he went to Algiers, and during a month there spent he obtained materials for a paper on land and freshwater Mollusca, published in the *Annals of Natural History*, vol. ii. p. 250. In the autumn of the same year he registered at Edinburgh as a student of literature; and in 1838 appeared his first volume, *Malacologia Monensis*, a synopsis of the species of Manx Mollusca. During the summer of 1838 he visited Styria and Carniola, and made extensive botanical collections. In the following autumn he read before the British Association at Newcastle a paper on the distribution of terrestrial Pulmonifera in Europe, and was commissioned to prepare a similar report with reference to the British Isles. On returning to Edinburgh he delivered a course of 15 lectures on the natural history of the animals in the British seas. In 1841 was completed the publication of Forbes's great work, *A History of British Star-fishes*, embodying the results of researches carried on for a long series of years, and containing 120 illustrations, inclusive of humorous tail-pieces, all designed by the author. On April 17th of the same year Forbes, accompanied by his friend William Thompson, joined at Malta H.M. surveying ship "Beacon," to which he had been appointed naturalist by her commander Captain Graves. From that date until October, 1842, he was busily employed in investigating the botany, zoology, and geology of the Mediterranean region. The results of his researches were made known in his "Report on the Mollusca and Radiata of the Ægean Sea, presented to the British Association in 1843," and in *Travels in Lycia*, published in conjunction with Lieut. Spratt in 1846. In the former treatise he discussed the influence of climate and of the nature and depth of the sea bottom upon marine life, and divided the Ægean into eight biological zones; his conclusions with respect to bathymetrical distribution, however, have been shown by later investigators to require certain considerable modifications. Towards the end of the year 1842 Forbes, whom family misfortunes had now thrown upon his own resources for a means of livelihood, sought and obtained the curatorship of the collections of the Geological Society of London. To the duties of that post he, in May of the following year, added those of the professorship of botany at King's College, where he lectured with success to the second largest botanical class in London. On November 1, 1844, having resigned the curatorship of the Geological Society, he became palæontologist to the Geological Survey, with a yearly salary of £300. In 1846 Forbes published in the *Memoirs of the Geological Survey*, i. 336, his important treatise "On the Connection between the existing Fauna and Flora of the British Isles, and the Geographical Changes which have affected their Area." It is therein pointed out that, in accordance with the theory of their origin from various specific centres, the plants of Great Britain may be divided into five well-marked groups:—the W. and S.W. Irish, represented in the N. of Spain; the S.E. Irish and S.W. English, related to the flora of the Channel Isles and the neighboring part of France; the S.E. English, characterized by species occurring on the opposite French coast; a group peculiar to mountain summits, Scandinavian in type; and, lastly, a general or Germanic flora. From a variety of arguments the conclusion is drawn that the greater part of the terrestrial animals and flowering plants of the British Islands migrated thitherward, over continuous land, at three distinct periods, before, during, and after the glacial epoch. In the autumn of 1848 Forbes married the daughter of General Sir C. Ashworth. The year 1851 witnessed the removal of the collections of the Geological Survey from Craig's Court to the new museum in Jermyn Street, and the appointment of Forbes as professor of natural history to the Royal School of Mines just established in conjunction therewith. In 1852 was published the fourth and concluding volume of Forbes and Hanley's *History of British Mollusca*. In 1853 Forbes held the presidency of the Geological Society of London, and in the following year he obtained the fulfilment of a long-cherished wish in his appointment to the professorship of natural history in the university of Edinburgh vacant, by the death of Jameson, his former teacher. Since his return from the East in 1842, the determination and arrangement of fossils, the investigation of strata, frequent lectures, and incessant and wearing literary work, including the preparation of his admirable palæontological memoirs, and of a variety of scientific articles and reviews, had precluded Forbes from giving that attention to the natural history pursuits of his earlier life which he had for years earnestly desired. It seemed that at length he was to find leisure to reduce to order and commit to the keeping of the press those vast stores of biological information of which long-protracted and original research had made him the possessor. At Edinburgh, in the summer season of 1854, he lectured to a large and appreciative audience; and in September of that year he occupied the post of president of the geological section at the meeting of the British Association. He had already commenced his winter's course of lectures in Edinburgh when he was seized with feverishness, culminating in an attack of nephritic disease, from which he had on several previous occasions been a sufferer. His symptoms soon became alarming, and after not many days' illness he expired at Wardie, near Edinburgh, Nov. 18, 1854, in the fortieth year of his age.

See *Literary Gazette*, November 25, 1854; *Edinburgh New Philosophical Journal* (New Ser.), 1855; *Quar. Journ. Geol. Soc.*, May, 1855; G. Wilson and A. Geikie, *Memoir of Edward Forbes*, 1861, in which, pp. 575–583, is given a list of Forbes's writings. See also the Royal Society's *Catalogue of Scientific Papers*, vol. ii. pp. 654–658. (F. H. B.)

FORBES, James David (1809–1868), successively professor of natural philosophy in the university of Edinburgh and principal of the United College in the university of St. Andrews, was the fourth son of Sir William Forbes of Pitsligo, the lineal representative of the Forbeses of Monymusk and Pitsligo. His mother was Wilhelmina Belches-Stuart, sole child and heiress of Sir John Stuart of Fettercairn. Their family consisted of two daughters and four sons, of whom James David, born at his father's town house, 86 George Street, Edinburgh, on the 20th April, 1809, was the youngest. Two years after his birth, the death of Lady Forbes took place. Sir William retired with his family from Edinburgh to Colinton, his country residence, and thus it happened that, up to the age of sixteen, when he entered college, James Forbes was entirely a home-bred boy, and his only teacher the schoolmaster of the village. At an early age, however, he developed remarkable powers of self-education. Passionately fond of natural science, he stored his mind with all available knowledge of physics, constructed for himself astronomical instruments, and actually commenced a connected series of meteorological observations, which he kept up for many years. But these pursuits were carried on without the knowledge of his family; for Sir William had destined him for the bar, and Forbes loved his father too well to betray tastes and inclinations which might seem to point towards a different career. In November, 1825, he entered the university of Edinburgh, and joined the classes of Latin and chemistry. He still continued his self-imposed studies, and at length forwarded anonymously to Sir David (then Dr.) Brewster, who was at the time conducting the *Edinburgh Philosophical Journal*, a paper on "The Apparent Number of the Stars." It was at once inserted, and further communications were requested from the anonymous "Δ." The request was complied with, and during an extended tour through France, Germany, and Italy, in company with a large family party, Forbes contributed a number of papers on "The Physical Geography of the Bay of Naples," "The Horary Oscillations of the Barometer at Rome," and other subjects, all of which were inserted in the *Journal*. On his return to Scotland after a year's absence, he made himself known to Brewster as his unknown correspondent. Brewster, astonished at his extensive reading and remarkable powers of observation, encouraged him in his scientific pursuits and proposed him as a fellow of the Royal Society of Edinburgh, to which, at the age of 19, he was elected. In the mean time he had re-entered college, where his subsequent career was a distinguished one. In the class of moral philosophy, taught by the celebrated Professor Wilson, he gained the highest honors, and in Sir John Leslie's natural philosophy class he twice carried off the gold medal. An event now occurred which changed the whole tenor of his life. His father died on the 24th of October, 1828, and it became necessary that Forbes should seriously consider his future course of life. The choice lay between the bar and a scientific career, and after much consultation with his friends he chose the latter. He passed his law trials indeed, and put on his advocate's gown, but never wore it, for a competence given him by his father had rendered him independent. About this time Sir David Brewster was engaged in laying the foundations of the British Association. Forbes joined cordially in the work, and contributed much towards placing the Association on the basis it now occupies. Throughout the rest of his life he attended, with rare exceptions, all its meetings, often breaking off a foreign tour, and hastening back to do so. The presidency of the meeting held at Dundee in 1867 was offered to him, but ill health compelled him to decline it.

Immediately after his election as fellow of the Royal Society of London, in June, 1832, Forbes started on an extensive scientific tour, but was suddenly recalled from Geneva by news of the death of Sir John Leslie, professor of natural philosophy at the university of Edinburgh. Forbes had left word that should this chair at any time become vacant, he desired to be put in nomination, and on his return found that this had actually been done. He also found himself, to his surprise and dismay, the rival of his old friend Sir David Brewster. But Forbes was already committed, and had received testimonials from Whewell, Airy, Peacock, Vernon Harcourt, Chalmers, and others, bearing high testimony to his attainments, and the immense results they promised. After a more than usually excited contest, into which politics to some extent entered, Forbes was elected, at the age of twenty-four, to a professorial chair of the highest distinction. The inaugural lecture with which he opened the session of 1833–34 was listened to with unusual interest. As a professor, he more than realized the high expectations which had been formed of his special capacity for the work. During the twenty-seven years of his professorship his lectures left no branch of natural philosophy untouched, and owing to his thorough acquaintance with the literature of the subject, each of them was a mass of condensed information,—not, however, confined to old knowledge taken from books, but enriched from time to time by the results of original research, enlivened by many a happy illustration drawn from his travels and adventures, and rendered more effective by his clear ringing voice and graceful delivery. He soon gathered round him an enthusiastic body of hard-working students, and although the high standard he aimed at made him a somewhat strict disciplinarian, their personal interest in his researches and their pride in his success increased as years went on. Forbes took an interest in his students no less personal, and more than one acquaintance formed in the class-room ripened into a tender and affectionate friendship. But his energies were not confined to the work of his professorship; they soon made themselves felt throughout all the machinery of the university. The system of examination for degrees—already for some time in operation at Oxford—was then much wanted at Edinburgh, where, owing to the absence of any sufficient test of proficiency, graduation was little valued and seldom sought for. Forbes became an energetic reformer in this direction, and to him is mainly owing the complete system of examination for degrees which, under his guidance as dean of the faculty of arts, greatly tended to raise the standard of Scottish education. Again, in 1841, there was much discussion in the senatus as to the disposal of a large sum of money bequeathed by General Reid for the foundation of a chair of music and for other purposes. Forbes strongly opposed the idea of a musical professorship, urging that the money would be more usefully employed in providing retiring allowances for superannuated professors. But controversy ran high, litigation ensued, and after years of contention a part of the Reid bequest was assigned by the law courts to the chair of music. Next year another large sum, the Straton fund, had to be dealt with, and here again Forbes was instrumental in inducing the senate to devote what was left of the Reid bequest, combined with the Straton fund, to the foundation of fellowships to be held by distinguished students after graduation. In these and other controversies the uncompromising energy with which he strove to carry out his views of what was right could not fail to bring him into collision with men whose opinions were as decided, and their wills as strong as his own. When two such unbending natures as Sir William Hamilton and James Forbes came into contact—as they did more than once—the shock was a rough one; but although they differed widely in opinions, each has left a permanent mark for good on the university.

It would be impossible to enter here into the subjects or method of Forbes's class lectures; nor is it necessary to give more than a brief notice of the important researches which shared with his class work the winter months. They were the subject of voluminous private correspondence with such men as Whewell, Brewster, Peacock, Airy, Faraday, Arago, Melloni, Cauchy, and many others, and their results were embodied in a long list of communications to various scientific societies, ranging over a great variety of subjects.

For a paper on "The Transparency of the Atmosphere and the Laws of Extinction of the Sun's Rays passing through it," the Royal Society of London awarded him their Royal medal. Another, on "The Selective Absorption of the Sun's Light in passing through steam," was one of the first steps in the direction of spectrum analysis. In 1832 he described the experiments by which he succeeded in producing a spark by means of a natural magnet. He was the author of valuable memoirs on the thermal springs of the Pyrenees, the extinct volcanoes of the Vivarais (Ardêche), and the geology of the Cuchullin and Eildon hills. Soon after his elevation to the chair Forbes resumed his researches in heat, begun some years before. He commenced experiments with Melloni's thermo-multiplier, measured the refractive index of rock salt with heat from various sources, luminous and non-luminous, and pursued a course of investigations which led him to his most brilliant discovery, the polarization of non-luminous heat by transmission through tourmaline and thin mica plates, and by reflection from the latter. By employing mica for depolarization he succeeded in showing the double refraction of non-luminous heat, a fact of which this experiment remains the only proof. He also produced circularly polarized heat by two internal reflections, using Fresnel's rhombs made of rock salt. By these researches the identity of thermal and luminous radiations was finally established. In 1846 he made careful arrangements for the measurement of underground temperatures, and by sinking his thermometers in three different sets of surface materials, he obtained an absolute determination of the thermal conductivity of traptufa, sandstone, and pure loose sand. His experiments on the conductivity of metals occupied the closing years of his life. By a thoroughly original method he obtained quantitative measurements of the absolute thermal conductivity of iron at various temperatures, and showed that this is diminished (contrary to the assumption of Fourier) by increase of temperature, thus following the known laws of electrical conductivity.

Forbes generally devoted a part of each vacation to excursions with his family in various parts of Scotland, and to geological tours among his native mountains, in the course of which, at times in company with some scientific friend, more often alone, he traversed on foot the greater part of the Highlands. In 1856 he acquired a beautiful cottage near Pitlochrie in Perthshire, where the succeeding summers were chiefly spent. From 1835 to 1851 Forbes usually passed some months on the Continent, travelling, as he expressed it, not as an amusement, but as a serious occupation, with De Saussure before him as a model. And it may be almost doubted whether science did not profit as much by his summer travels as by his winter work.

His first tour was devoted to the geology of the Pyrenees and of the Vivarais—the latter of which he afterwards revisited. In 1837, after a short sojourn at Bonn, for the purpose of study, he travelled throughout Germany and Austria, making frequent experiments on terrestrial magnetism and other subjects. In 1839, among the crags and glaciers of Monte Viso, of the Pelvoux range, and of the Alps of Cogne, he learned to be an active and intrepid mountaineer; and during the intervals of his glacier investigations he did good service in opening up Alpine districts before scarcely known to Englishmen, by a series of excursions extending over the whole of the Pennine chain.

But of all his journeys and discoveries, those made by him among the mountains of Savoy are most popularly known; and their results have associated his name for ever with the glaciers of the Alps. In 1840, while presiding over the physical section of the British Association at Glasgow, he met M. Agassiz of Neuchâtel—who, after spending several years in the study of glacial phenomena, had just published his *Études sur les Glaciers*,—and agreed to visit Switzerland with him the following year. Accordingly, at the close of the session of 1840-41, Forbes joined Agassiz and his party at the well-known "Hôtel des Neuchâtelois," a small hut on the moraine of the Lauter Aar Gletscher. After a fortnight spent in exploration and observation, in the course of which Forbes called attention for the first time to the veined structure of glacier ice, they ended the campaign by the passage of the Ober Aar Joch, and the ascent of the Jungfrau. This was Forbes's apprenticeship in glacier observation,—a field of inquiry then jointly occupied by two rival theories, the gravitation or sliding theory of De Saussure, and the dilatation theory of Charpentier. After a close analysis of these Forbes not only showed conclusive physical reasons for rejecting both, but pointed out the impossibility of forming a sound theory of glaciers until the internal structure of these anomalous bodies had been investigated, and the character and velocity of thei motions ascertained.

These important data Forbes resolved to obtain for himself, and the summer of 1841 found him at Chamounix, engaged in a close examination of the Mer de Glace. He attacked the problem for the first time as a question of pure physics, executed accurate measurements with instruments of precision, and at once established the fact that the motion of a glacier averages roughly a foot in 24 hours, and that such motion is continuous. As his observations went on, he successively discovered that the centre of the glacier moves faster than the sides, and the surface than the ice vertically below it, that its velocity increases directly with the steepness of its bed, and that the motion of a portion of the glacier when embayed behind a rock is greatly diminished, and the whole mass distorted, without any solution of continuity taking place. Convinced by these discoveries that the resemblance between a glacier and a river, already noticed by Captain Hall, Msgr. Rendu, and others, was more than a mere analogy, he deduced from the above mentioned data the following theory of glacier motion: — *A glacier is an imperfect fluid or a viscous body, which is urged down slopes of a certain inclination by the mutual pressure of its parts.* In reply to the strongly urged objection that ice is by its nature a brittle solid, and not sensibly possessed of any viscous quality, he asserted that ice is only hard and crystalline at a temperature of 30° F. or lower, and that at 32° it is a plastic solid possessing a slight but perfectly sensible genuine molecular plasticity. When the urgency of the forces to which it is subjected causes this limit to be overpowered, a general bruise takes place, producing innumerable internal fissures, with finite displacements in certain planes, and subsequent restoration of continuity by "time and cohesion;" hence the blue bands of the conchoidal veined structure. When the urgency is still greater the mass acts like a solid, and crevasses open. In the case of glacier ice an additional element of plasticity exists, for glacier ice is scarcely ever coherent. It is usually a congeries of irregular polyhedrons tightly wedged together, possessing a rude flexibility, and always traversed by an infinity of capillary fissures. Hence a glacier is really a compound of ice and water, more or less plastic according to its wetness and infiltration,—a fact proved by its more rapid motion in summer when saturated with water, and its relative retardation in winter when the surface water remains frozen. Forbes's "viscous theory" was sharply criticised, but it is now universally accepted, subject to some modifications which do not affect the groundwork of the structure, and rather elucidate than disprove his conclusions. But besides scientific criticism, he was compelled to defend himself—which he did with complete success—against insinuations not only of plagiarism, but of an endeavor to suppress the rights of others to priority of discovery.

During the winter which followed this eventful summer, Forbes was busily engaged in writing his *Travels through the Alps of Savoy*, a charming contribution to Alpine literature, in which graphic descriptions of scenery and mountaineering are happily blended with accounts of his scientific researches. Its last lines were written almost on the eve of his marriage with Alicia, eldest daughter of the late George Wauchope, Esq. They started on their marriage tour to Switzerland, but had only got so far as Bonn when Forbes was attacked by a dangerous illness, and it was not until August that they reached the Alps. He was then so far restored as to be able to resume his observations on the glaciers of Chamounix and Grindelwald, but as the winter approached he was pronounced unequal to the work of the following session at Edinburgh. His request for permission to appoint a substitute was readily granted, and he set out with Mrs. Forbes for Italy. Naples and Rome were their headquarters until the end of May, and the summer months were passed at the Italian lakes and in Switzerland. Forbes returned to Edinburgh in the autumn of 1844, and carried on his work during the winter months, but his health had suffered a rude shock, from the effects of which he never entirely recovered. The succeeding summer was spent with his family in the Highlands of Scotland; but the vacation of 1846 found him again on the Mer de Glace, engaged in observations on the ablation of the surface of the glaciers, and the difference of movement between the surface and the underlying ice. His next and last visit to the Alps in 1850 was entirely occupied in putting the finishing touches to his survey of the Mer de Glace, which was for some years after its publication the only correct Alpine map in existence. At the close of the session of 1850–51 he started for Norway with the double purpose of observing a total eclipse of the sun visible at Bergen, and of comparing the phenomena of the Arctic glaciers with those of the Alps. These objects were not attained without great fatigue and exposure. Forbes returned from Norway with health much impaired, and had scarcely recommenced his work when he was attacked by hæmorrhage, the precursor of a long and dangerous illness. All through December he lay between life and death, but in January he was able to be removed to Clifton, which he made his headquarters for two years. During this enforced leisure he was constantly engaged in writing a very able "Dissertation on the Progress of Mathematical and Physical Science" for the pages of the *Encyclopædia Britannica*, and in preparing for the press a work on *Norway and its Glaciers*, similar in character to his *Glaciers of the Alps*, and scarcely yielding to it in picturesqueness of narrative or careful observation. In the summer of 1853 he was called from Clifton to Oxford to receive the honorary degree of D.C.L. During the three sessions of Forbes's absence his class work had been conducted by Professor Kelland, but the session of 1854–1855 found him again at his post, and he worked with but little interruption from illness until 1859, assisted latterly by Dr. Balfour Stewart. In that year the current of his life was turned into another channel. Owing to the translation of Sir David Brewster to the principalship of the Edinburgh university, the principalship of the United College of St. Andrews became vacant; Forbes offered himself as a candidate, and was successful. His commission bears date December 2, 1859, but he did not resign his professorship until the following April. The degree of LL.D. was then conferred on him by the university which his own labors had so greatly benefited and adorned.

His new post, although it relieved him of the fatigue of constant lecturing, was no sinecure. The Scottish University Commission were then in full session, and in their investigations of the affairs, financial and other, of his own college and of the university, the responsibility of supplying information and suggesting reforms fell largely on him. A zealous reformer he always was, and he had not left behind him at Edinburgh that dauntless spirit of "Thorough" which saw only one straight road to a right principle, and pursued it, not without collisions, and often painful ones. The duties of his office were performed with scrupulous industry. His own college is indebted to him for a laborious examination and classification of its ancient charters. He found the collegiate church of St. Salvator in a condition of tasteless neglect; he left it partially restored and greatly beautified. He occasionally lectured on glaciers, climate, heat, and others of his favorite subjects, and even strained his failing powers to complete his researches on the thermal conductivity of iron. For the latter, shortly before his death, the Keith medal was awarded to him.

In the spring of 1867 Forbes's health gradually declined, and towards the end of September he set out with his wife and three daughters to Cannes, and afterwards went on to Hyères. His health now continued to improve until the middle of January, when he was again attacked by hæmorrhage brought on by fatigue. He never sat up again, and while in that painful state the presidency of the Royal Society of Edinburgh was offered to him and declined. It was evident that a summer at Hyères was impossible, so he was conveyed, together with one of his daughters who was almost in the same sad condition as himself, to Clifton, where he lingered for eight months, awaiting his end with patient calmness, sustained by the deep and fervent religious faith which had characterized his boyhood, and which a life of active scientific research had strengthened rather than impaired. He died on the 31st of December, 1868.

Forbes received the honorary degree of D.C.L. from Oxford, and that of LL.D. from the university of Edinburgh. The Royal Society of London awarded him their Rumford medal for his discovery of the polarization of heat, and their Royal medal for a paper on the influence of the atmosphere on the sun's rays. By the Royal Society of Edinburgh the Keith medal was thrice presented to him, and he filled the post of secretary to that body from 1840 till the failure of his health obliged him to resign it. In 1845 a pension of £200 a year was granted to him for his services rendered to science. He was fellow of the Royal Societies of London and Edinburgh, and of the Geological Society, corresponding member of the Imperial Institute of France, and associate or honorary member of the Bavarian Academy of Sciences, of the Academy of Palermo, of the Dutch Society of Sciences (Haarlem), of the Helvetic Society, of the Pontifical Society of the Pontifical Academy of "Nuovi Lincei" at Rome, and of the Natural History Societies of Heidelberg, Geneva, and Vaud, and honorary member of the Royal Medical Society of Edinburgh, of the Cambridge, Yorkshire, St. Andrews, and Isle of Wight Philosophical Societies, and of the Plymouth and Bristol Institutions.

A list of his scientific writings is to be found in the Royal Society *Catalogue*, but the following books may be mentioned as bearing more particularly on his glacier researches:—*Travels through the Alps of Savoy*, Black, Edin., 1843, 1845; *Norway and its Glaciers*, Black, Edin., 1853; *Occasional Papers on the Theory of Glaciers*, Black, Edin., 1859. See also *Théorie des Glaciers de la Savoie*, par M. le Chanoine Rendu (translated by Alfred Wills, edited by Professor George Forbes), Macmillan, Lond., 1874.

Forbes's Life and Letters, by Principal Shairp of St. Andrews, Prof. P. G. Tait, and A. Adams-Reilly, was published by Macmillan, London, 1873. (A. A. R.)

FORBES, Sir John (1787–1861), M.D., was born at Cuttlebrae, Banffshire. He attended the Grammar School at Aberdeen, and afterwards entered Marischal College. Having for nine years been assistant-surgeon and surgeon in the navy, he in 1817 graduated at Edinburgh, and then commenced practice in Penzance, whence he removed to Chichester. He took up his residence in London in 1840, and was the same year appointed Physician to the Prince Consort, and in 1841 physician to the Queen's household. He was a fellow of the Royal Society, and D.C.L. of Oxford; and in 1853 he received the honor of knighthood. He died November 13, 1861, at Whitchurch in Berkshire.

Sir John Forbes was better known as an author and editor than as a practical physician. His works include the following:—*Original Cases . . . illustrating the Use of the Stethoscope and Percussion in the Diagnosis of Diseases of the Chest*, 1824; *Illustrations of Modern Mesmerism*, 1845; *A Physician's Holiday*, 1st ed. 1849; *Memorandums made in Ireland in the Autumn of 1852*, 2 vols., 1853; *Sight-seeing in Germany and the Tyrol in the Autumn of 1855*, 1856. He was joint editor with Drs. Tweedie and Conolly of *The Cyclopædia of Practical Medicine*, 4 vols., 1833–35; and in 1836 he founded the *British and Foreign Medical Review*, which, after a period of prosperity, involved its editor in pecuniary loss, and ceased to exist, in consequence of the advocacy in its later numbers of doctrines obnoxious to the profession.

FORBIN, Claude de (1656–1733), French naval commander, was born in Provence, of a family of high standing, in 1656. High-spirited and ungovernable in his boyhood, he ran away from his home, and through the influence of an uncle entered the navy, serving his first campaign in 1675. For a short time he quitted the navy and entered the army, but soon returned to his first choice. He made under D'Estrées the American campaign, and under Duquesne that of Algiers in 1683, on all occasions distinguishing himself by his impetuous courage. The most remarkable episode of his life was his mission to Siam. During the administration of the Greek adventurer Faulcon in that country, the project was formed of introducing the Christian religion and European civilization, and the king sent an embassy to Louis XIV. In response a French embassy was sent out, Forbin accompanying the Chevalier de Chaumont with the rank of major. When Chaumont returned to France, Forbin was induced to remain in the service of the Siamese king, and accepted, though with much reluctance, the posts of grand admiral, general of all the king's armies, and governor of Bankok. His position, however, was soon made untenable by the jealousy and intrigues of the minister Faulcon; and at the end of two years he left Siam, reaching France in 1688. He was afterwards fully engaged in active service, first with Jean Bart in the war with England, when they were both captured and taken to Plymouth. They succeeded in making their escape, and were soon serving their country again. Forbin was wounded at the battle of La Hogue, and greatly distinguished himself at the battle of Lagos. He served under D'Estrées at the taking of Barcelona, was sent ambassador to Algiers, and in 1702 took a brilliant part in the Mediterranean in the war of the Spanish succession. In 1706 he took command of a squadron at Dunkirk, and captured many valuable prizes from the Dutch and the English. In 1708 he was entrusted with the command of the squadron which was to convey the Pretender to Scotland; but so effectually were the coasts guarded by Byng that the expedition failed and returned to Dunkirk. Forbin was now beginning to be weighed down with the infirmities of age and the toils of service, and in 1710 he retired to a country house near Marseilles. There he spent part of his time in writing his memoirs, published in 1730, which are full of interest and are written in a graphic and attractive style. Forbin died March 4, 1733.

FORCELLINI, Egidio (1688–1768), an Italian philologist, was born at Fener in the district of Treviso, and belonged to a very poor family. He went to the seminary at Padua in 1704, studied under Facciolati, and in due course attained to the priesthood. From 1724 to 1731 he held the office of rector of the seminary at Ceneda, and from 1731 to 1765 that of father confessor in the seminary of Padua. The remaining years of his life were mainly spent in his native village. He died at Padua in 1768 before the completion of the great work by which his name is preserved. This is a vast *Latin Lexicon*, usually referred to as Facciolati's, which has formed the basis of all similar works that have since been published. He was engaged with his Herculean task for nearly 35 years, and the transcription of the manuscript by Luigi Violato occupied eight years more. It was ultimately published at the expense of Cardinal Priole, under the title of *Totius Latinitatis Lexicon, consilio et cura Jacobi Facciolati, opera et studiis Ægidii Forcellini, Seminarii Patavini Alumni, lucubratum*, 4 vols., Padua, 1771.

FORCHHAMMER, Johan Georg, a Danish mineralogist and geologist, was born at Husum on July 26, 1794, and died at Copenhagen on December 14, 1865. After studying at Kiel and Copenhagen from 1815 to 1818, he joined Oersted and Esmarch in their mineralogical exploration of Bornholm, and took a considerable share in the labors of the expedition. In 1820 he obtained his doctor's degree by a chemical treatise *De Mangano*, and immediately after set out on a journey through England, Scotland, and the Faroe Islands. In 1823 he was named university lecturer on chemistry and mineralogy; in 1829 he obtained a similar post in the newly established polytechnic school; and in 1831 he was appointed professor of mineralogy in the university, and as such became curator of the geological museum. On the death of Oersted in 1851, he succeeded him as director of the polytechnic school and secretary of the academy of sciences. As a public instructor Forchhammer held a high place and contributed potently to the progress of his favorite studies in his native country. He delighted in the popularization of science, and frequently brought his knowledge and influence to bear on such practical questions as the introduction of gas into Copenhagen, the establishment of the fire-brigade at Rosenberg, or the boring of artesian wells.

Among his more important works are—*Lærebog i de enkelte Radicalers Chemi*, 1842; *Danmarks geognostiske Forhold*, 1835; *Om de Bornholmske Kulformationer*, 1836; *Dit nyere Kridt i Danmark*, 1847; *Bidrag til Skildringen af Danmarks geographiske Forhold*, 1858. A list of his contributions to scientific periodicals, Danish, English, and German, will be found in the *Catalogue of Scientific Papers* published by the Royal Society of London. One of the most interesting and most recent is "On the constitution of sea water at different depths and in different latitudes," in the *Proceedings of the Roy. Soc.*, xii., 1862–1863.

FORCHHEIM, a fortified town of Bavaria, circle of Upper Franconia, is situated near the junction of the Wiesent with the Regnitz, 16 miles S.S.E. of Bamberg. It has a castle, a collegiate and two other churches, a synagogue, a monastery, and a hospital. Its industries include brewing, tanning, soap-boiling, and glass manufacture. Forchheim is of very early origin. Charlemagne transplanted thither in 804 a number of Saxons from the Elbe, and made it an important commercial entrepôt. In the 9th and 10th centuries many assemblies, both of the princes and the kingdom were held at Forchheim, and in 890 a council of the church. In 1007 it was presented by the emperor Henry II. to the newly founded bishopric of Bemberg, but in 1040 Henry III. united it again to the kingdom. Henry IV., however, again presented it to the bishopric of Bemberg, with which it remained till 1802, when it came into the possession of Bavaria. In 1552 it was captured by the Margrave Albert of Brandenburg, and in 1634 besieged by Bernhard of Weimar. Its fortifications were restored in 1791. On the 6th and 7th August, 1796, a battle took place near it between the French and Austrians, when the French held possession of the field. Forchheim ceased to occupy the position of a fortified town after 1838. The population in 1875 numbered 3847.

FORD, John (1586–*c.* 1640), one of the most noteworthy writers of the English old drama in the period of its first decline, was born in 1586 at Ilsington in North Devon. He came of a good family; his father was in the commission of the peace, and his maternal grandfather, Sir John Popham, was successively attorney-general and lord chief justice. John Ford, like his cousin and namesake (to whom, with other members of the society of Gray's Inn, he dedicated his play of *The Lover's Melancholy*), entered the profession of the law, being admitted of the Middle Temple in 1602; but he seems never to have been called to the bar. Four years afterwards he made his first appearance as an author with an elegiac effusion called *Fame's Memorial, or the Earl of Devonshire deceased*, and dedicated to the widow of the earl (Charles Blount Lord Mountjoy, "coronized," to use Ford's expression, by King James in 1603 for his services in Ireland, which the elegy celebrates)—a lady who would have been no unfitting heroine for one of Ford's tragedies of lawless passion, the famous Penelope formerly Lady Rich. This panegyric, which is accompanied by a series of epitaphs, and is composed in a strain of fearless extravagance, was, as the author declares, written "unfee'd;" it shows Ford to have sympathized, as Shakespeare himself is supposed to have done, with the "awkward fate" of the countess's brother, the earl of Essex. Who the "flint-hearted Lycia" may be, to whom the poet seems to allude as his own disdainful mistress, is unknown; indeed, the record of Ford's private life is, like that of the lives of so many of our old dramatists, little better than a blank. To judge, however, from the dedications, prologues, and epilogues of his various plays, he seems to have enjoyed the patronage or goodwill of several men of rank—among them the excellent earl (afterwards duke) of Newcastle, "himself a muse" after a fashion, and the gallant Lord Craven, supposed to have been the husband of the ex-queen of Bohemia. Ford's tract of *Honor Triumphant, or the Peeres Challenge* (printed 1606), and the simultaneously published verses *The Monarches Meeting, or the King of Denmarkes welcome into England*, exhibit him as an occasional contributor to the festive demands of court and nobility; and a kind of moral essay by him, entitled *A Line of Life* (printed 1620), which contains a few not uninteresting references to Raleigh, ends with a climax of praise to the address of "a good man, of whom it may be verified that he is *bonorum maximus* and *magnorum optimus*"—viz., King James I. Yet it may be noted in passing that one of Ford's plays contains an implied protest against the absolute system of government which usually found ready acceptance with the dramatists of the early Stuart reigns.[1] Of our poet's relations with his brother-authors little is known; it was natural that he should exchange complimentary verses with Shirley, a more various though less intense dramatic poet of his own age and school, and that he should join in the chorus of laments with which the poets of the time mourned the decease of their acknowledged veteran chief, Ben Jonson. It is more interesting to notice an epigram in honor of the author of *Love's Sacrifice* and

---

[1] *Crot.*—"The king hath spoke his mind.
Org.— "His will he hath;
But were it lawful to hold plea against
The power of greatness, not the reason, haply
Such undershrubs as subjects sometimes might
Borrow of nature justice, to inform
That license sovereignty holds without check
Over a meek obedience."
The Broken Heart, act iii. sc. 4.

The Broken Heart by a poet of a very different kind, but in whose genius it is not paradoxical to assert that there were points of contact with Ford's—Richard Crashaw, morbidly passionate in one direction as Ford was in another. Towards the public Ford seems, by reason either of his social position or of his personal character, to have assumed an attitude of independence; but for an assailant of the theatre, such as the author of *Histriomastix*, he displays, like his friend Shirley, a dramatist's inevitable scorn.

It has been concluded, from evidence of a rather vague description, that in the latter part of his life he gratified the tendency to seclusion for which he has been thought to be ridiculed in a contemporary poem, by withdrawing from business (it had probably been legal business of one kind or another), and from literary life in London, to his native place; but nothing is known as to the date of his death. His career as a dramatist very probably began with some plays in which he assisted, or was assisted by, other authors. The titles of these (all we possess of them) are not without significance. With Dekker he wrote *The Fairy Knight* and *The Bristowe Merchant;* with Webster *A Late Murther of the Sonne upon the Mother*. A play attributed to Ford alone, and entitled *An ill Beginning has a good End*, was brought on the stage as early as 1613; and in 1615 followed *Sir Thomas Overbury's Life and untimely Death*—a subject to which the poet devoted some lines, which are preserved, of indignant regret. He also wrote, at dates unknown, *The London Merchant* and *The Royal Combat;* a tragedy by him, *Beauty in a Trance*, was entered in the Stationers' Register in 1653, but never printed. Of the plays by Ford preserved to us the dates span little more than a decade—the earliest, *The Lover's Melancholy*, having been acted in 1628 and printed in 1629, the latest, *The Lady's Trial*, acted in 1638 and printed in 1639.

When writing *The Lover's Melancholy*, it would seem that Ford had not yet become fully aware of the bent of his own dramatic genius, although he was already master of his powers of poetic expression. We may suppose him, when he first became a dramatic author, to have been attracted towards both domestic tragedy and romantic comedy—to the former by an irresistible desire to sound the depths of abnormal conflicts between passion and circumstances, to the latter by a strong though not widely varied imaginative faculty, and by a self-delusion (such as will alone account for his repeated—and nearly always unsuccessful—efforts in this direction) that he was possessed of abundant comic humor. In his next two works, undoubtedly those most characteristically expressive of his peculiar strength, viz., *'Tis Pity she's a Whore* and *The Broken Heart* (both printed 1633), he had found themes the horrible situations in which required dramatic explanation by intensely powerful motives. Ford by no means stood alone among our dramatists in his love of abnormal subjects; but few were so capable of treating them sympathetically, and at the same time without that reckless grossness or extravagance of expression which renders the morally repulsive æsthetically intolerable, or converts the horrible into the grotesque. For in Ford's genius there was an element of true refinement, except when the self-delusion referred to came into play. In a third tragedy, *Love's Sacrifice* (also printed in 1633) he again worked on similar materials; but this time he unfortunately essayed to base the interest of his plot upon an unendurably unnatural possibility—doing homage to virtue after a fashion in which to honor is almost equivalent to insulting her. He might seem by this time to have been in danger of indulging still further a morbid tendency, the corroding influence of which is fatal to any genius abandoning itself to it; yet we find him in *Perkin Warbeck* (printed 1634) choosing an historical subject, and, alone among the dramatists of his age, seeking to emulate the glory of the great series of Shakespeare's national histories. It is true that his treatment of his theme, though neither unskilful nor unworthy, could not at once compass the breadth and variety which this species of drama demands. But the effort is one of the most commendable, as it was by no means one of the least successful, in the dramatic literature of this period; and we may unhesitatingly regret that he should not have made another essay in the same field, instead of turning to romantic comedy, for which he was without the requisite buoyancy of spirit, while all but devoid of the faintest vestige of comic humor. *The Fancies Chaste and Noble* (printed 1638), though it includes scenes of real force and feeling, is dramatically a failure, of which the main idea is almost provokingly slight and feeble; and *The Lady's Trial* (acted 1638, printed 1639) is only redeemed from utter wearisomeness by an unusually even pleasingness of form. There remain two other dramatic works, of very different kinds, in which Ford co-operated with other writers, the mask of *The Sun's Darling* (acted 1624, printed 1657), which is hardly to be placed in the first rank of early compositions, and *The Witch of Edmonton* (printed 1658, but probably acted about a quarter of a century earlier), in which we see Ford as a joint writer of one of the most powerful domestic dramas of our own or any other stage.

A few notes may be added on some of the more remarkable of the plays enumerated. A wholly baseless anecdote, condensed into a stinging epigram by Endymion Porter, asserted that *The Lover's Melancholy* was stolen by Ford from Shakespeare's papers. Lesser dramatists are in the habit of borrowing from greater; and there were few among the writers of our old drama, of whatever eminence or calibre, to whom plagiarism, whether in the matter of situations and characters, or of passages and expressions, would have seemed a literary liberty requiring defence. Undoubtedly, the madness of the hero of this play of Ford's occasionally recalls Hamlet, while the heroine is one of the many, and at the same time one of the most pleasing, parallels to Viola. But neither of them is a copy, as Friar Bonaventura in Ford's second play may be said to be a copy of Friar Lawrence, whose kindly pliability he disagreeably exaggerates, or as D'Avolos in *Love's Sacrifice* is clearly modelled on Iago. The plot of *The Lover's Melancholy*, which is ineffective because it leaves no room for suspense in the mind of the reader, seems original; in the dialogue, on the other hand, a justly famous passage in Act i. (the beautiful version of the story of the nightingale's death) is translated from Strada; while the scheme of the tedious interlude exhibiting the various forms of madness is avowedly taken, together with sundry comments, from that storehouse of useless learning, Burton's *Anatomy of Melancholy*. Already in this play Ford exhibits the singular force of his pathos; the despondent misery of the aged Meleander, and the sweetness of the last scene, in which his daughter comes back to him, alike go to the heart. A situation—hazardous in spite of its comic substratum—between Thaumasta and the pretended Parthenophil is conducted, as Gifford points out, with real delicacy; but the comic scenes are merely stagey, notwithstanding, or by reason of, the effort expended on them by the author.

'Tis Pity she's a Whore has been justly recognized as a tragedy of extraordinary power; but it seems no hard matter to join in this recognition, while reserving to one's self the right, which no canon of criticism can rebut, of protesting against the abuse of art of which this play furnishes an almost unparalleled example. Mr. Swinburne, in his eloquent essay on Ford, has rightly shown what is the meaning of this tragedy, and has at the same time indicated wherein consists its poison. He dwells with great force upon the different treatment applied by Ford to the characters of the two miserable lovers—brother and sister. "The sin once committed, there is no more wavering or flinching possible to him, who has fought so hard against the demoniac possession; while she who resigned body and soul to the tempter almost at a word, remains liable to the influences of religion and remorse." This different treatment shows the feeling of the poet—the feeling for which he seeks to evoke our inmost sympathy—to oscillate between the belief that an awful crime brings with it its awful punishment (and it is sickening to observe how the argument by which the Friar persuades Annabella to forsake her evil courses mainly appeals to the physical terrors of retribution), and the notion that there is something fatal, something irresistible, and therefore in a sense self-justified, in so dominant a passion. The key-note to the conduct of Giovanni lies in his words at the close of the first scene—

"All this I'll do, to free me from the rod
Of vengeance; *else I'll swear my fate 's my god.*"

Thus there is no solution of the conflict (which in one form or the other all men have to undergo) between passion on the one side, and law, duty, and religion on the other: and passion triumphs, in the dying words of "the student struck blind and mad by passion"—

"O, I bleed fast!
Death, thou'rt a guest long looked for; I embrace
Thee and thy wounds: O, my last minute comes!
Where'er I go, let me enjoy this grace
Freely to view my Annabella's face."

It has been observed by a recent critic of mark that "English poets have given us the right key to the Italian temperament. . . . The love of Giovanni and Annabella is rightly depicted as more imaginative than sensual." It is difficult to allow the appositeness of Mr. J. A. Symonds's special illustration; on the other hand, Ford has even in this case shown his art of depicting sensual passion without grossness of expression; for the exception in Annabella's language to Soranzo seems to have a special intention, and is true to the pressure of the situation and the revulsion produced by it in a naturally weak and yielding mind. The entire atmosphere, so to speak, of the play is stifling, and is not rendered less so by the underplot with Hippolita.

Like this tragedy, *The Broken Heart* was probably founded upon some Italian or other novel of the day; but since in the latter instance there is nothing revolting in the main idea of the subject, the play commends itself as the most enjoyable, while, in respect of many excellences, an unsurpassed specimen of Ford's dramatic genius. The complicated plot is constructed with greater skill than is usual with this dramatist, and the pathos of particular situations, and of the entire character of Penthea—a woman doomed to hopeless misery, but capable of seeking to obtain for her brother a happiness which his cruelty has condemned her to forego—has an intensity and a depth which are all Ford's own. Even the lesser characters are more pleasing than usual, and some beautiful lyrics are interspersed in the play.

Of the other plays written by Ford alone, *The Chronicle Historie of Perkin Warbeck—A Strange Truth* alone appears to call for special attention. A repeated perusal of this drama suggests the judgment that it is overpraised when ranked at no great distance from Shakespeare's national dramas. Historical truth has not to be taken into consideration in the matter; and if (notwithstanding Mr. Gairdner) there are still credulous persons left to think and assert that Perkin was not an impostor, they will derive little satisfaction from Ford's play, which with really surprising skill avoids the slightest indication as to the poet's own belief on the subject. That this tragedy should have been reprinted in 1714 and acted in 1745 only shows that the public, as is often the case, had an eye to the catastrophe rather than to the development of the action. The dramatic capabilities of the subject are, however, great, and it afterwards attracted Schiller, who, however, seems to have abandoned it in favor of the similar theme of the Russian Demetrius. Had Shakespeare treated it, he would hardly have contented himself with investing the hero with the nobility given by Ford to this personage of his play,—for it is hardly possible to speak of a personage as a *character* when the clue to his conduct is intentionally withheld. Nor could Shakespeare have failed to bring out with greater variety and distinctness the dramatic features in Henry VII., whom Ford depicts with sufficient distinctness to give some degree of individuality to the figure, but still with a tenderness of touch which would have been much to the credit of the dramatist's skill had he been writing in the Tudor age. The play is, however, founded on Bacon's *Life*, of which the text is used by Ford with admirable discretion. The minor characters of the honest old Huntley, whom the Scottish king obliges to bestow his daughter's hand upon Warbeck, and of her lover the faithful "Dalyell," are most effectively drawn; even "the men of judgment," the adventurers who surround the chief adventurer, are spirited sketches, and the Irishman among them has actually some humor; while the style of the play is, as befits a "Chronicle History," so clear and straightforward as to make it easy as well as interesting to read.

The Witch of Edmonton was attributed by its publisher to William Rowley, Dekker, Ford, "etc.," but the body of the play has been generally held to be ascribable to Ford and Dekker only. Mr. Swinburne agrees with Gifford in thinking Ford the author of the whole of the first act; and he is most assuredly right in considering that "there is no more admirable exposition of a play on the English stage." Supposing Dekker to be chiefly responsible for the scenes dealing with the unfortunate old woman whom persecution as a witch actually drives to become one, and Ford for the domestic tragedy of the bigamist murderer, it cannot be denied that both divisions of the subject are effectively treated, while the more important part of the task fell to the share of Ford. Yet it may be doubted whether any such division can be safely assumed; and it may suffice to repeat that no domestic tragedy has ever taught with more effective simplicity and thrilling truthfulness the homely double lesson of the folly of selfishness and the mad rashness of crime. To us such plays as this are singularly interesting, both as pictures of the manners of the age which they depict without the effort more or less perceptible in comedy, and as illustrations of a species of the modern drama which, in its best examples, is perhaps of all the least liable to essential change.

With Dekker, Ford also wrote the mask of *The Sun's Darling*; or, as seems most probable, they founded this production upon *Phaeton*, an earlier mask, of which Dekker had been sole author. Gifford holds that Dekker's hand is perpetually traceable in the first three acts of *The Sun's Darling*, and through the whole of its comic part, but that the last two acts are mainly Ford's. If so, he is the author of the rather forced occasional tribute on the accession of King Charles I., of which the last act largely consists. This mask, which furnished abundant opportunities for the decorators, musicians, and dancers, in showing forth how the seasons and their delights are successively exhausted by a "wanton darling," Raybright the grandchild of the Sun, is said to have been very popular. It is at the same time commonplace enough in conception; but there is much that is charming in the descriptions, Jonson and Lyly being respectively laid under contribution in the course of the dialogue, and in one of the incidental lyrics.

Ford holds a position of his own among our dramatists of the second order. This he owes not to his skill as a constructor of plots, which he at times prepares better than he executes them, thus verifying the observation that the supreme skill of the dramatist lies, not in devising or finding the chief situation of his play, but in the harmonious building-up of the action and development of the characters towards it. Nor does he owe it even to the beauty of his versification, the fluency and strength of which are incontestable, notwithstanding a certain obscurity of style. His peculiar power lies in the intensity of his passion, in particular scenes and passages where the character, the author, and the reader are alike lost in the situation and in the sentiment evoked by it; and this gift is a supreme dramatic gift. But his plays—with the exception of *The Witch of Edmonton*, in which he doubtless had a prominent share—too often disturb the mind like a bad dream which ends as an unsolved dissonance; and this defect is a supreme dramatic defect. It is not the rigid or the stolid who have the most reason to complain of the insufficiency of tragic poetry such as Ford's; nor is it that morality only which, as Ithocles says in *The Broken Heart*, "is formed of books and school-traditions," which has a right to protest against the final effect of the most powerful creations of his genius. There is a morality which both

> "Keeps the soul in tune,
> At whose sweet music all our actions dance,"

and is able to physic

> "The sickness of a mind
> Broken with griefs."

Of that morality—or of that deference to the binding power within man and the ruling power above him—tragedy is the truest expounder, even when it illustrates by contrasts; but the tragic poet who merely places the problem before us, and bids us stand aghast with him at its cruelty, is not to be reckoned among the great masters of a divine art.

The best edition of Ford is that by Gifford, with notes and introduction, revised with additions to both text and notes by the late Mr. Dyce (3 vols. 1869). Mr. Swinburne's "Essay on Ford," to which reference has been made in this article, is reprinted among his *Essays and Studies* (1875). (A. W. W.)

FORD, RICHARD (1796–1858), author of one of the earliest and best of travellers' *Handbooks*, was the eldest son of Sir Richard Ford, who in 1789 was member of parliament for East Grinstead, and for many years afterwards chief police magistrate of London. His mother was the daughter and heiress of Benjamin Booth, who was a distinguished connoisseur in art, and from whom his grandson seemed to have inherited the artistic skill and taste which he developed to so high a pitch of excellence in his writings, his sketches, and his collections from Continental countries, particularly Spain. He was educated at Winchester, graduated at Trinity College, Oxford, and was called to the bar in Lincoln's Inn. Ford, however, never practised the profession of a lawyer, and in 1830 he landed for the first time in Spain, where he travelled for three years, spending much of his time in the Alhambra, and at Seville. On his return to England in 1833, he settled in Devonshire at Heavitree, near Exeter, where, writes his friend, the late Sir William Stirling Maxwell, "he built himself a charming residence, and surrounded it with gardens and terraces, which he adorned with graceful Moorish buildings, and planted with pines and cypresses from historic groves by the Xenil and Guadalquiver." From 1837 to 1857 he contributed to the *Quarterly Review*, his first contribution to that periodical being a paper on the apparently uninviting subject of Devonshire cob walls, and his last a review of *Tom Brown's School Days*. His first work was the pamphlet, *An Historical Inquiry into the Unchangeable Character of a War in Spain* (Murray, 1837), in reply to one called the *Policy of England towards Spain*, and issued under the patronage of Lord Palmerston. He spent the winter of 1839–40 in Italy, where he added largely to his collection of majolica; and soon after his return he began, at Mr. Murray's invitation, to write his *Handbook for Travellers in Spain*, the literary work with which his name is chiefly associated. In consequence of the failure of his health, he was obliged to resign his seat on a royal commission that had been appointed, in the winter of 1856–57, to report on the best site for the National Gallery, and he died on the 31st August, 1858.

FORD, THOMAS, an English musician, of whose life little more is known than that he was attached to the court of Prince Henry, son of James I. His works also are few, but they are sufficient to show the high stage of efficiency and musical knowledge which the English school had attained at the beginning of the 17th century. They consist of canons and other concerted pieces of vocal music, mostly with lute accompaniment. The chief collection of his works is entitled *Musike of Sundrie Kinds set forth in Two Books*, etc., 1607, and the histories of music by Burney and Hawkins give specimens of his art. Together with Dowland, immortalized in one of Shakespeare's sonnets, Ford is the chief representative of the school which preceded Henry Lawes, the great master of declamatory music, who, according to Milton,

> "First taught our English music how to span
> Words with just note and accent."

In this art, however, Ford is by no means deficient, his songs showing great care in the exact rendering of the words, with regard to both accent and meaning.

FORDUN, JOHN OF. Little is known with any certainty of this chronicler, and the so-called lives of him are mainly a collection of conjectures more or less probable. The credulity of our early writers is pardonable; the nonsense of some later ones is without excuse. A notice inserted in the *New Statistical Account* of the parish of Fordoun in Kincardineshire begins thus:—"John of Fordun, the historian, was either a native of the parish or resident in it, when he wrote his history of Scotland. He is called by Bede 'venerabilis vir Dominus Joannes Fordun, Presbyter.'" The writer's notions of chronology must have been somewhat peculiar. The statement generally made that the chronicler was born at Fordoun has apparently no better foundation than his name. It is certain that he was a secular priest, and that he composed his history in the latter part of the 14th century; and it is probable that he was a chaplain in the cathedral of Aberdeen. The work of Fordun is the earliest attempt to write a continuous history of Scotland; nothing existed previously except brief chronicles and genealogical memoranda. It is divided into five books. The first three are almost entirely fabulous, and form the groundwork on which Boece and Buchanan afterwards raised the huge structure of historical and political fiction, which was first exposed by Thomas Innes in his *Critical Essay*. The 4th and 5th books, though still mixed with fable, contain much valuable information, and become more authentic the more nearly they approach the author's own time. The 5th book concludes with the death of King David I. in 1153. Besides these five books, Fordun wrote part of another book, and collected materials for bringing down the history to a later period. These materials were used by a continuator who wrote in the middle of the 15th century, and who is commonly, and no doubt correctly, identified with Walter Bower, abbot of the monastery of Inchcolm. The additions of Bower form eleven books, and bring down the narrative to the death of King James I. in 1437. According to the custom of the time, the continuator did not hesitate to interpolate Fordun's portion of the work with additions of his own, and the whole history thus compiled is known as the *Scotichronicon*. The first printed edition of Fordun's work was that of Thomas Gale in his *Scriptores Quindecim*, which was published in 1691. This was followed by Thomas Hearne's edition in 1722. The whole work, including Bower's continuation, was published by Walter Goodall at Edinburgh in 1759. In 1871 and 1872 Fordun's chronicle, in the original Latin and also in an English translation, was edited by Mr. William F. Skene in the series of *The Historians of Scotland*. Mr. Skene's preface to this valuable edition contains full information both in regard to the author, the manuscripts of his work, and the printed editions. Reference may also be made to Thomas Innes's *Critical Essay*, vol. i. pp. 201–214; to the biographical notice of Fordun in the second volume of *Tytler's Lives of Scottish Worthies*; and to Mr. Felix G. H. Skene's preface to the "Liber Pluscardensis," in the series of *The Historians of Scotland*.

FORESTS, FOREST ADMINISTRATION. A forest is a tract of country covered with trees, of one or several species, or with trees and underwood. Forests are of the greatest importance in the general economy of the globe influencing the humidity of the air and the soil, mitigating the extremes of heat and cold, affording shelter to man and beast, and enriching the soil on which they grow. Trees supply timber and fuel to man, and furnish him with a vast variety of economical products, such as gums, drugs, dyes, and articles of food. The management of large areas of natural or planted wood-lands is called Forestry or Sylviculture. For the culture and uses of individual trees, see the separate articles, such as BIRCH, ELM, FIR, OAK, etc.; and for ornamental belts, avenues, etc., the reader is referred to ARBORICULTURE.

Historical records give us reason to believe that the habitable earth was generally covered with forest growth before it became the abode of man, and additional proof of this is found in the extensive remains of ancient trees. The geological record may also be referred to, as evidencing by its coal-fields the extensive breadths once covered by the richest vegetation.

The arboreous vegetation of the earth is remarkable for its great variety; many countries are rich in pines, others in oaks; Australia in Eucalyptus or gum trees, India in teak, California in Wellingtonia or Sequoia, and Brazil in palms. Trees, like other plants, require different degrees of heat, light, moisture, and elevation above the sea for their vigorous development, and hence various countries have their characteristic forests. The birches and pines of the North make way in the temperate zone for oaks and beeches, and in the tropics for palms and other heat-loving trees. The same trees seem to require similar climates, but the same climates do not always produce the same plants. The mountains of South India and Ceylon closely resemble the regions where the cinchona forests occur, but the genus is wanting in Asia. Again the teak is unknown in America, although parts of Brazil resemble its home in Malabar. These anomalies are explained perhaps mainly by the primitive distribution of the plants (see DISTRIBUTION). It is also remarkable that some forests consist solely of one particular tree (on the Continent technically called "pure forest," in contradistinction to mixed forests), such as the birch in Lapland, the deodar in the Himalaya, the *Abies canadensis* and *Pinus Strobus* in North America. The European forests, on the contrary, are generally composed of coniferous trees mingled with oak, elm, ash, beech, poplar, willow, alder, birch, and lime, interspersed with hornbeam, and various species of *Pyrus* and *Prunus*, the underwood being hazel, elder, buckthorn, viburnum, roses, etc. The American forests contain a still greater variety of species, a fact strikingly illustrated by Sir J. D. Hooker, in speaking of a patch of native forest a few miles from St. Louis on the Missouri:—"In little more than half an hour, and less than a mile's walk, I saw forty kinds of timber trees, including eleven of oak, two of maple, two of elm, three of ash, two of walnut, six of hickory, three of willow, and one each of plane, lime, hornbeam, hop-hornbeam, laurus, diospyros, poplar, birch, mulberry, and horse-chestnut, together with about half that number of shrubs."

Natural forests may be divided into several classes, and in Kurz's forest flora of British Burmah the classification adopted is as follows:—

Evergreen Forests.

1. Littoral Forests.
2. Swamp Forests.
3. Tropical Forests.
4. Hill Forests.

Deciduous or Leaf-Shedding Forests.

5. Open Forests.
6. Dry Forests.
7. Mixed Forests.
8. Dune Forests.

The following table, calculated by Rentzsch (*Der Wald*), from statistics obtained prior to 1862, shows the proportion of woodland in different European countries, as estimated at that date:—

Norway	66·00 per cent.	Sardinia	12·29 per cent.
Sweden	60·00 "	Neapolitan States	9·43 "
Russia	30·90 "	Holland	7·10 "
Germany	26 58 "	Spain	5·52 "
Belgium	18·52 "	Denmark	5·50 "
France	16·79 "	Great Britain	5·00 "
Switzerland	15·00 "	Portugal	4·40 ".

Siemoni gave in 1872 the proportion in Turkey at 24 per cent., and in United Italy 8·70 per cent.

For comparison, we quote from the most recent official abstract the Population, Area, and Acreage under Wood in the United Kingdom and various foreign countries, according to returns furnished by the agricultural and statistical departments of the respective countries.

	Population.	Area (in English Acres).	Woods and Forests (in Acres).	Proportion of Woodland.
Great Britain (1877).......	26,072,284	55,802,360[1]	2,187,078	3·92
Ireland (1877)..............	5,412,377	20,327,196[1]	328,413	1·62
United Kingdom, including Isle of Man and Channel Islands (1877).............	31,629,299	76,323,203[1]	2,515,491	3·29
Russia in Europe (1872).	71,730,980	1,244,367,351[2]	527,426,510	42·38
Sweden (1875)	4.383,291	100,514.956[1]	40,636,883	40·43
Norway (1870)...............	1,742,000	77,527,766[1]	17,290,000	22·30
Denmark (1876)	1,784,741	8,572,929[1]	364,474	4·25
Prussia (1876)	24,643,623	85,834.703[1]	20,047,014	23·35
Baden (1876)..................	1,507,179	3,726,080[3]	1,337,767	35·90
Würtemberg (1876)........	1.881,503	4,786,114[1]	1,494,147	31·22
Holland (1875)................	3.865,456	7,761.528[1]	486,229	6·27

Norway..............	22·30	"			

The discrepancies observable in these tables are in some cases apparent; thus the latest returns from Russia, Sweden, Norway, etc., are exclusive of sheets of water, whereas in the same returns the area of France, Italy, and Switzerland includes the lakes and rivers. Great Britain also now includes the Isle of Man and Channel Islands. In other cases the discrepancies are real, arising from the greater accuracy of information which has been collected through Government organizations, which did not exist when the estimate of Rentzsch was made. An entire comparison is unattainable, but it will be observed that the largest proportion of woodland is in Russia, Sweden, Germany, and Austria. The lowest occurs in Britain, Denmark, Holland, Spain, and Portugal.

The physical history of every country proves incontestably that a moderate extent of forest promotes in a high degree both its agricultural and its manufacturing interests, as well as the productive resources of the country at large; and the beneficial influence of forests in a physical, economical, and hygienic aspect is now receiving more of the attention its importance deserves. The countries bordering the Mediterranean—Spain, France, Italy, and Turkey—have all suffered in a marked degree from the reckless and wholesale destruction of the woods which covered the mountain slopes, and many springs which formerly existed under the shelter of the forest have now wholly disappeared. Though the insular position and moist climate of the British Isles save them from suffering from the want of forest in an equal degree with Continental nations, the Anglo-Saxon race has been slow to apprehend the value of the forests with which nature has so liberally clothed the earth, and the history of North America, South Africa, Australia, and New Zealand bears testimony to the same improvidence and need of consideration. There can be no doubt that one of the causes of the terrible famines in India and China is the unwise denudation of mountain slopes, where the forests formerly absorbed a large portion of the rainfall which now quickly runs off to the sea (see CLIMATE). No point has been more clearly established than the salubrious and fertilizing effect of forest clothing in the climate of India. It has been the subject of much inquiry, and has been affirmed and demonstrated in reports from many districts.

We propose in this article to indicate briefly the principal wooded tracts of the earth, so far as known, and to describe the systems of conservancy adopted or the preliminary measures taken for the better management of state forests. Timber trees and forest produce will be briefly enumerated, but for the distinctive flora the reader is referred to the separate article on each country.

Forest science constitutes a separate branch of education in various countries of Europe. The first technical instruction was given in the Hartz forest, and Germany has taken the lead in developing a wise forest administration. France, Italy, Sweden, and Russia have successively established forest academies, and now the conservation of woodland occupies the legislature of almost all civilized lands.

The general systems of forest management in Britain and on the Continent are essentially different. Beautiful enclosures and plantations are seen in almost every part of England and Scotland. With the exception, however, of coppice wood and a limited extent of natural forest in the Highlands of Scotland, the system generally followed is to cut down the mature crop and to plant again. But on the Continent natural reproduction is the rule, not of wood coppice only, but also of high forest. In France the term of maturity for cutting a forest is determined with great care by a committee of skilled officers, and is usually divided into periods of so many years each; the term for an oak forest, for example, say 150 years, is divided into five periods of thirty years. Each series of years represents so many blocks or portions of forest, and the yearly cuttings are arranged so as to cover a certain extent of ground, and when one block has been felled another reaches maturity. France has a state department for the administration of the forests, and a very detailed code of forest laws (*Code Forestier*). The relation of woods to the regular drainage of the soil, and especially to the permanence of the configuration of the terrestrial surface, has been thoroughly investigated. The methods of resisting the encroachment of sands or dunes have also received special attention. In Germany forestry is eagerly followed as a profession, and forest academies are numerous and well organized. The examination of candidates is very strict, and the result of the system has been most beneficial. In forest science Germany is far advanced, and the literature is specially rich. Every tract is carefully surveyed and treated on a working plan made with great exactness as to actual details and expected growth; care is always taken that in high forest there is a good stock of self-sown trees before the old crop is entirely removed. Systematic observation and experiments are made as to the rate of growth, and the best soil for each description of tree.

In Italy, where the French and German systems have been tested, the principles of sylviculture adopted by Hartig, Cotta, etc., are not always applicable in the drier climate of the south. On the arid slopes of the Apennines pasture is more profitable, and there is as yet little sympathy with skilled conservation of woods.

EUROPE.

Great Britain and Ireland.—The British Isles were formerly much more extensively wooded than at present. The rapid increase of population has led to the disafforesting of woodland; the climate requires the maintenance of household fires during a great part of the year, and there has been an increasing demand for arable land; these along with the extension of manufacturing industries have been the chief causes of the diminution of wood. The proportion of forest is now very small, and yields but a fraction of the required annual supply of timber, which is imported with facility from America, northern Europe, and the numerous British colonies.

Owing to the nature of the climate of the British Islands, with its abundance of atmospheric moisture and freedom from such extremes of heat and cold as are prevalent in continental Europe, a great variety of trees are successfully cultivated. In England and Ireland oak and beech are on the whole the most plentiful trees in the low and fertile parts; in the south of Scotland the beech and ash are perhaps most common, while the Scotch fir and birch are characteristic of the arboreous vegetation in the Highlands. Although few extensive forests now exist, woods of small area, belts of planting, clumps of trees, coppice, and hedgerows are generally distributed over the country, constituting a mass of wood of considerable importance, giving a clothed appearance in many parts, and affording illustrations of skilled arboriculture not to be found in any other country.

The principal state forests in England are Windsor Park, 14,000 acres, the New Forest, etc., in Hampshire, 76,000 acres, and the Dean Forest in Gloucestershire, 22,500 acres. The total extent of crown forests is about 125,000 acres, and the timber growing upon them is valued at between two and three millions of pounds. A large proportion of the crown forests, having been formed with the object of supplying timber for the navy, consists of fine oak. These wooded tracts are under careful management. The total receipts from the royal forests exclusive of Windsor amounted in 1876–77 to £33,129. The largest forests in Scotland are in Perthshire, Inverness-shire, and Aberdeenshire. Of these the most notable are the earl of Mansfield's near Scone (8000 acres), the duke of Atholl's larch plantations near Dunkeld (10,000 acres), and in Strathspey a large extent of Scotch fir, partly native, partly planted, belonging to the earl of Seafield. The last-named forest has been regularly planted in such a gradation as to cut 1000 acres annually on a rotation of sixty years. In the forests of Mar and Invercauld, the native pine attains a very great size, and there are also large tracts of indigenous birch in various districts. The total area under wood in Scotland is less than it was in 1812 by 200,000 acres. Ireland was at one time richly clothed with wood; this is proved by the abundant remains of fallen trees in the bogs which still occupy a large surface of the island. In addition to the causes above alluded to as tending to disafforest England, the long unsettled state of the country also conduced to the diminishing of the woodlands. At present indigenous timber is exceedingly scarce, the proportion of woodland being only 1·62. The abundance of peat compensates in some measure for the want of wood as fuel.

The following acreages of land and woodland in the United Kingdom are taken from the agricultural returns of 1877:—

	Total Area, including Water.	Woods, Coppices, and Plantations.
England	32,597,398	1,325,765
Wales	4,721,823	126,823
Scotland	19,496,132	734,490
Ireland	20,819,829	325,173
	77,635,182	2,512,251

In England, the woods, except the crown forests, being generally on a small scale and private property, there has been no legislative interference with their management. No uniform system of education has been adopted, and a school of forestry is much required. Meanwhile the Highland and Agricultural Society of Scotland grants certificates for proficiency in the theory and practice of forestry tested by examination. Excellent instruction in surveying, botany, chemistry, geology, and collateral subjects is given in Edinburgh, at the Royal Agricultural College, Cirencester, at Glasnevin, Dublin, and in other places.

Norway and Sweden.—The peninsula formed by the kingdoms of Norway and Sweden is abundantly wooded. The principal trees are Scotch fir (*Pinus sylvestris*), spruce fir (*Abies excelsa*), and birch (*Betula alba*). These grow to a large size, and the birch extends almost as far as the North Cape, only giving place at high altitudes to low bushy willows. In the southern districts only is there any variety of hard wood. The forests are principally situated in the east of Norway. The western parts have been denuded, and the wants of the sea-coast are supplied from the inland districts.

Of the vast area of waste land returned as forest in Norway, about one-ninth belongs to the state or to various state institutions. In the greater part of the forests the population have a long established right for grazing, timber, and firewood; and even in tracts in which landowners or the state have a part ownership, the rights of the population, if they have any, take precedence of all other claims. Communal forests are managed by men chosen from among those who jointly own them. From the 16th century various laws attempted to regulate the private forests, but these were found vexatious, and were repealed in 1836. The forest department for the control of state forests consists of 27 officers, with a very large staff of men employed in felling and timber transport. The export of timber from Norway is chiefly from the Skeen Fiord, and the various ports between Cape Lindesnaes and the Swedish border. The annual export amounts to about 80,000,000 cubic feet, more than half being sent to Great Britain and Ireland, while the average annual value is estimated at £2,400,000. Some idea of the great timber resources of Norway may also be gathered from the fact that in the census of 1865 there were 4937 men entered as working in the forests, and 17,549 described themselves as employed in woodwork, saw-mills, tar-preparing, etc. In a Norwegian administration report it is stated that "the present destruction of forests has reached the limit of the permissible, probably even exceeded it."

Of the 100,500,000 acres in the kingdom of Sweden, 88,800,000 were officially reported in 1875 as forest waste land, 12 millions being public, and 76 millions private property. Only about half of this, however, is really covered with wood, including plantations formed in recent years. Of the public forests only 4 million acres are under direct state management; about an equal area remains to be demarcated, while the rest belongs to other public institutions, is attached to state residences, or is temporarily alienated. The trees in Sweden are the same as those of Norway, but oak, elm, lime, alder, and beech grow more extensively in the south. Birch-wood is chiefly used as fuel, and the wood of the aspen is largely employed in the manufacture of matches.

Forest management in Sweden is in course of progressive development, and the administration is conducted with energy. The department consists of a director and 700 men of different administrative and executive grades. Much labor is required to bring the timber to market from remote forests in the western part of the kingdom; in winter sledges on ice and snow are used for transport, and in floating down the rivers logs often take four and five years to reach the timber dépôt. Besides the control of the state and other public forests, the department is entrusted with the surveillance of private forests.

In 1875 the total revenue of the state forests was £56,807. The actual expenditure was £35,787. The profits were therefore £21,020. The shipments of timber are annually increasing, and were in 1874 325,061 loads, and 704,741 standards. A Government forest school at Stockholm, which in 1875 had 13 students, supplies recruits for the higher grades of forest service, while there are six provincial schools for training men for the subordinate posts. Besides these, there is a private forest school receiving a grant in aid from Government.

Denmark is one of the most poorly wooded countries in Europe, the percentage of woodland being now only 4·25 of the whole area. This small proportion is caused chiefly by the nakedness of the western part of Jutland, where the west winds have seconded the action of man in destroying the forests. Much of the wood which at one time covered nearly the whole of Denmark having been cut down, to make way for agriculture, and to supply fuel and timber, a vast area thus bared has become a sandy heathy desert. The chief indigenous trees of Denmark are the spruce and Scotch fir, birch, and aspen. The oak also forms valuable forests on the islands of Falster and Lolland. Beech, which was later introduced, has flourished so well as almost to monopolize the forest ground, and special protection is afforded to the oak, while a variety of conifers are being introduced as rivals to the beech; in a few places only, such as Normandy and the Carpathian mountains, are beech forests so luxuriant as in Denmark. Although laws to check the destruction of forests were enacted in the 15th, 16th, and 17th centuries, they were treated as a dead letter; it is only since 1805 that effective measures have been taken to preserve the remains of Danish woodland and to create new plantations. A State forest department permits only small portions of old forests to be cleared at a time, and insists on the simultaneous planting of an equal area. The department also exercises a controlling supervision on private forests, forming plantations where necessary on private estates at the expense of the owner. About one-fifth of the entire area of Denmark may be described as lying waste; some of this is unfit for the growth of trees, but already extensive plantations have been formed, on the heaths and dunes of West Jutland, of hardy trees such as *Pinus montana*, *Abies alba*, *A. excelsa*, and *A. pectinata*. In some instances, the State purchases tracts of heath on which to form plantations, and in others grants aid to private enterprise.

The Danish forest school is at Copenhagen, and forms a branch of an agricultural college. Admittance is obtained after passing an examination similar to that required for matriculation at the university. The forest education requires four examinations, and the subjects comprised are—(1) mathematics, geology, natural philosophy, chemistry, zoology, botany, and drawing; (2) practical work, to acquire a knowledge of which the student generally arranges to serve for a year or two under a forest officer; (3) an oral examination in the principles of forestry, surveying, geology, hydrology, forest zoology, and botany; and (4) these principles applied practically, a tract of forest above 200 acres to be surveyed, and levels found for a line of 3000 or 4000 feet. The course of study extends from four to six years; the student then becomes a "forest candidate," and may look for Government employment.

Holland, on account of its formation and climate, possesses no indigenous forests. The country is so intersected by water that it is extremely subject to fogs, and being little above the sea level it is greatly exposed to winds, those from the north-west especially being prejudicial to tree growth, while the marshy ground prevents the roots from penetrating far into the soil. There is, however, along the roads and embankments, a considerable amount of timber, consisting of beech, poplar, willow, and ash, which attain a large size, and in the management of such avenues the Dutch excel. Elms also thrive on the embankments. The extensive dunes, amounting to 140,000 acres, are planted chiefly with hardy conifers (Marsh).

Belgium.—The physical features of Belgium are, except in the northern part, very different from those of Holland. The chief forests are in the districts of Brabant and Flanders, and the old forest of Ardennes still extends along the south-eastern frontier. According to Siemoni, in 1872 Belgium had 18 per cent. of her soil covered with wood. Recent returns give the area of state forest in Belgium as nearly 75,000 acres, and of communal forests 300,000 acres, all being under Government control.

Germany is in general well wooded, the forests of Prussia being estimated to cover 23·35 per cent. of the whole surface; while Würtemberg has 31·22, and Baden 35·90. This wealth is partly due to the abundant natural supply, and partly to the methodical way of treating forests adopted by all the states of the empire. The winters being long and severe, an abundant supply of fuel is almost as essential as a sufficient supply of food. This necessity has led, in the absence of coal, and along with a passion for the chase, to the preservation of forests, and to the establishment of an admirable system of forest cultivation, almost as carefully conducted as field tillage. We need only enumerate a few of the principal wooded tracts bordering on the Rhine and the Elbe. The Black Forest stretches the whole length of the grand-duchy of Baden and part of the kingdom of Würtemberg, from the Neckar to Basel and the lake of Constance. The vegetation resembles that of the Vosges; forests of spruce, Scotch, and silver firs, mingled with birches, beech, and oak, are the chief woods met with. The forest of Rippoldsau, on the head waters of the Kinzig, is one of the best forests, and is managed with great care. In the grand-duchy of Hesse, the Odenwald range of mountains, stretching between the Maine and the Neckar, contains the chief supply of timber. These two large tracts of forest are favorably situated with respect to water carriage, and from them the supply of timber for exportation is mainly drawn; it is now, however, so much diminished in passing down the Rhine through populous districts, that it no longer suffices for the demands of the Dutch shipbuilders. The largest spars are called "Holländer." The floating operations down the several tributaries of the Rhine in the Black Forest are very instructive, and the timber trade may there be studied with advantage. In the duchy of Nassau there are the large wooded tracts of the Westerwald and the Taunus mountain ranges, and the forests cover a large area extending between Neuwied and Bieberich. In Rhenish Prussia the valuable forests nearly equal the arable land in extent. These lie partly in the Ardennes, on the borders of Belgium, and on the mountains overhanging the Upper Moselle, but they do not furnish such stately trees as the Schwarzwald or Black Forest and the Odenwald. The Vosges forests were ceded to Germany in 1872, after the Franco-Prussian war. The Spessartwald, near Aschaffenburg-on-the-Maine in Bavaria, is one of the most extensive forests of middle Germany, containing large masses of fine oak with extensive plantations of coniferous trees, spruce, Scotch fir, and larch. Bavaria possesses other fine forest tracts, such as the Baierischewald on the Bohemian frontier, the Kranzberg near Munich, and the Frankewald in the north of the kingdom. North Germany has extensive forests on the Hartz and Thuringian mountains, while in East Prussia large tracts of flat ground are covered with *Pinus sylvestris*, *Abies excelsa*, and juniper.

Prussia, including Hanover, contains about 20 million acres of forest land. About half of this is private property, and of the other half, managed by the state, part is communal or ecclesiastical forest. Of the state forests, equalling 6,200,000 acres, a small proportion is moorland yet to be planted. The yield of the state woodland in 1871, a large portion of which bears Scotch fir, was 204,796,260 cubic feet, or 34·5 cubic feet per acre of the area devoted to the produce of timber. The total income for the year for timber and other forest products amounted to £2,100,000, or about six shillings an acre, little more than half of which went to working expenses, the cost of the forest academies, commutation of servitudes, and road taxes.

Much has been done in Germany to preserve and develop the forest resources by establishing training schools, with the result that sylviculture has been most accurately studied, and the economical management of woodland most successfully carried out in that country. The following eight academies existed prior to the unification of the empire. Each large state had one school. They are now being remodelled with a central office at Berlin.

Eisenach in Thuringia, Saxe Weimar.
Tharant near Dresden, Saxony.
Neustadt Eberswald, near Berlin.
Münden in Hanover.
Giessen in Hesse.
Carlsruhe in Baden.
Hohenheim, near Stuttgart, in Würtemberg.
Aschaffenburg in Bavaria.

The academies at Neustadt Eberswald and Aschaffenburg are for the study of forestry alone, while in the others the pursuit of agricultural or engineering knowledge is combined with it. In Germany the forest service is a state department, filled by youths of good position, who are specially trained for the purpose. The period of training extends over five years, and its course is thus described by Campbell Walker.[1]

> "Nothing struck me as more remarkable than the extent and varied nature of the studies required from forest candidates or probationers in Prussia, and the number of years they are content to spend, first in studying and then in waiting for an appointment. The would-be *oberförster* must, after passing certain terms at a Government school of the first class, spend a year with an oberförster in a 'revier,' and then pass an examination as forest pupil, after which there is a two years' course at a forest academy, and an examination in scientific forestry, land surveying, etc., on passing which the pupil becomes a *forst-kandidat;* then other two years' practical study, during at least nine months of which he must actually perform the duties of a forester, after which comes the final Government examination, on passing which he enters the grade of *oberförster-kandidat*. The difference betwixt the two examinations is that the first tests the candidate's knowledge of theoretical forestry and cognate sciences, whilst the latter tests his ability to apply what he has learnt and capability for employment as oberförster and in the higher grades. After passing the final examination the *oberförster-kandidat* is employed as an assistant in the academies and control offices, in making forest surveys and working plans, and sometimes acting in charge of a revier, receiving certain daily or weekly allowances whilst so employed. After five or six years of this probation he may look forward to being permanently appointed. Thus we have at least five years spent in study and other five in probation,—the former without any pay, and the latter only with meagre allowances, whilst actually employed, before the would-be forest officer is installed; and the time is generally much longer. Yet so great is the desire for Government service, and particularly forest service, in Prussia, and indeed in Germany generally, that there is no lack of competitors.
>
> "The forests form part of the revenue department, and are presided over by an *oberland-forstmeister* and *ministerial direktor*, aided by a revenue councillor and joint *ministerial direktor* and a numerous council, with suitable establishments and secretaries for the various branches. . . . The *oberland-forstmeister* is governor of the academies, and at the head of each is an *ober-forstmeister*, aided by a numerous staff of professors and assistants. . . . There is a control office of account at Potsdam, where all the forest accounts of the several provinces are finally audited before going to the ministry of finance. . . . The 12 provinces of Prussia are divided into 30 circles (*Regierungsbezirk*), and to each of these an *ober-forstmeister* is appointed to represent the forest department in the council of local administration (*Regierung*), and aided by councillors and by the *forst-*

---

[1] *Reports on Forest Management*, London, 1872.

meisters, as a board, to represent forest interests in the Government, and administer the department to the best advantage. Next in order come the *forstmeisters*, numbering 108, in charge of divisions with an average area of 25,000 hectares, and then the executive officers, 706 *oberförsters*, with charges averaging about 3000 hectares, to each of which is attached a *forstrendant*, or collector of forest revenue, and 3646 *försters* (or overseers), with ranges of from 500 to 1000 hectares. The forests have all been surveyed, valued, and divided into blocks, and there are accurate maps representing the extent and situation of each forest district, and the description and age of the timber growing in each block. Whatever be the size of the woods every tree is recorded, and a working plan is drawn out and followed,—certain species being destined to longer or shorter growth, according to their promise of vitality or liability to decay. It may be remarked that such maps form the starting point of every true system of forestry."

At Aschaffenburg, which may be taken as an example of German forest schools, candidates for Government forest service must first pass the standard of the higher school or gymnasium, which includes classics, mathematics, natural history, and chemistry. They are usually seventeen to nineteen years of age, and they first become apprentices for one year, assisting in the practical work of a forest district. The forest curriculum extends over two and a half years. Besides the director, there are four professors, who teach the following subjects:

I. *Forestry*. General management, planting operations, valuation surveys, rotation and details of working plan, transport and sale of timber and other forest produce.

II. *Natural Sciences*, with special reference to forest requirements: meteorological phenomena, organic chemistry, nutrition of plants, systematic botany and zoology, entomology.

III. *Mechanics*. *Surveying* and *Engineering*, with *Road-making*.

IV. *Forest Legislation* and *Police*.

Practical instruction is given in the laboratory, and excursions are made in the forest. The students who pass the final examination, after five years' training, are qualified for appointments in the forest service. Careful observations are made at Aschaffenburg regarding the influence of forests on the air and soil, their hygienic importance and effect on climate.

Austria.—Austria, including Hungary and Bohemia, possesses a vast amount of timber, about one-third of the productive area being returned as woodland, and covering 66,000 square miles, situated more in the east than in the west. There are 2,330,000 acres of forest belonging to the state, chiefly in Croatia, Slavonia, Transylvania, and the Alpine regions throughout the empire. Dalmatia and Istria alone have a deficient supply of timber, owing to previous devastations; but the Government is here making great efforts to restore the forests. The prevailing trees in the higher altitudes are *Abies excelsa* and *pectinata* and *Pinus montana* and *Laricio*. The larch mingles largely with the pines. In the low-lying tracts of the Alps and Carpathian mountains the beech is the principal tree; in the north-west several species of oak; in the south the elm, poplar, chestnut, and walnut. In Dalmatia and southern Tyrol the olive, mulberry, and fig trees abound. Austria produces annually about 67 million cubic feet of timber; and of other forest products the following are principal items:—

500,000 cwts. gall-nuts.	250,000 cwts. turpentine and resin.
100,000 " potash.	4,000,000 " tanning bark.

The total income in 1872 from the Austrian state forests was 4,148,000 gulden, the expenditure 3,049,000 gulden, leaving a net profit of about £90,000. The Austrian Government are wisely desirous to conserve and utilize their valuable forest property, and there is a state forest department with a staff of 1170 persons, 22 of whom are skilled officers of high position. In parts of Bohemia and Hungary entire forests have been destroyed, rendering useless much soil that is unfit for agriculture. Encouragement is given by the state to persons who make successful efforts to plant denuded ground.

Scientific forestry is not so advanced as in Germany, but increasing attention is being given to the subject. The principal forest academies are at Marien-brunn near Vienna, with a large staff of professors, a laboratory and museum, and at Schemnitz in Hungary. The courses last three years after passing the gymnasium examination, as at Aschaffenburg. Other academies for training more exclusively in the practice of forestry have a shorter course.

Russia.—The inequality of the distribution of wood in the Russian empire is very remarkable. The north of Great Russia, the government of Perm, and Finland have a large proportion of forest land, and the export of timber from Archangel, St. Petersburg, and Riga is very great. In central Russia there are also large and valuable forests, but in the south they become scanty. It was recently reported at the annual meeting of the geographical society of Vienna by Councillor Wex, that the Volga is decreasing in volume owing to the destruction of wood in its valley, so as to affect materially the level of the Caspian Sea and Sea of Aral. With the exception of Bessarabia and the Caucasus, including the region south-west of the Caspian, the southern districts of Russia bordering the Black and Caspian Seas are extremely bare of wood, and for household fuel the people use a compost of straw, leaves, etc. The Government has attempted the planting of portions of the vast steppes, and near Odessa there are fine plantations of *Ailanthus glandulosa*, which give promise of success to further plantings (Marsh). The following statistics of the proportion of woodland in Russia are given in the *Journal of Forestry*, 1877:—

"There are in European Russia alone 172,418,000 dessiatins (about 400,500,000 acres) of forests, or 43·3 per cent. of the entire territory. Such an extent of forests is not to be found in any other country of Europe. Two-thirds, or 66 per cent., of the mass of forests extend over the north-eastern districts; then follow the north-western governments, where the relative proportion to the general area is 30 to 50 per cent. In the middle Volga, the Baltic, and western and central provinces the proportion is 27·2 per cent., in the south-western it is 2·5 per cent., in the Little Russia and Steppe governments, including the Crimea, it is only 0·7 per cent. Finland and the Caucasus are not included, which contain splendid timber in great variety, nor the Polish governments, where the forests occupy a very extensive area."

In the Paris Exhibition Report, 1867, the area of forest in Finland is given at 2,500,000 acres, but in the most accessible parts wasteful and serious denudation has taken place.

The Scotch fir, the spruce, and the Siberian larch are the most common coniferous trees in Russia. The spruce penetrates furthest north, the Scotch fir grows well in the Crimea and the Caucasus, while the larch is chiefly found in the district drained by the Petchora river, and throughout Siberia. These three form the staple of the Russian timber export trade. Birch is also a tree of the northern latitudes, and extends eastwards as far as Kamchatka. In the central and over a large part of the southern portions of European Russia there are good forests of oak, and the beech, boxwood, ash, lime, maple, and walnut all grow in more or less profusion. The oak does not cross the Urals. The ridges of the Crimea are clothed with Corsican pine (*Pinus Laricio*), while the Scotch fir and beech form fine forests in the Caucasus.

The annual consumption of wood within the Russian empire is enormous, the estimated value being 260 millions of roubles, the railways requiring for fuel alone 7 million roubles' worth. In the absence of stone nearly all the buildings are made of wood. Every year upwards of 100,000 vessels of different descriptions descend the Russian rivers, most of which on reaching their destination are broken up for building or fuel. Scotch fir and spruce are usually employed for this purpose. The collection of resin and tar in the northern provinces is very great, about 7000 tons of tar being annually exported. A new industry has sprung up of late years, viz., making pulp for paper from the wood of the aspen, a tree which readily reproduces itself. The lime furnishes material for rope, cordage, and matting.

In 1858, Baron von Berg, a distinguished forest officer of Saxony, was requested to report on the forests and forest management of Finland, and subsequently also of Poland. The establishment of two schools of forestry resulted from his visit. At the school of Nova Alexandria in Poland, established in 1858, the teaching of agriculture is combined with that of forestry. The passing of a gymnasium examination is necessary before admission. The course of study covers three years, when, after the final examination, the students receive a diploma entitling them to employment in the service of Government. At Evois in Finland, where the school was founded in 1859, the instruction is in forestry only. Though at the commencement the education and quarters were given free, the school had to be closed for lack of pupils; but in 1874 it was reorganized, and now it seems to be in a flourishing condition. The course extends to two years, and the instruction includes forest law and economy, surveying, book-keeping, engineering, mathematics, and kindred subjects. A forest school also exists at Peteroffsky near Moscow, and another at Berdiansk on the Sea of Azoff, and many young Russians have been sent to the French and German schools to acquire a knowledge of forest science.

Roumania.—It is computed that there are in Roumania 2 million acres of forest land, though not wholly covered with wood. In the plains species of oak predominate, and according to elevation, walnut, beech, yew, silver fir, and spruce. But the coniferous trees have mostly disappeared, and the forests have been greatly damaged, while, owing to grazing rights, no young trees have been allowed to spring up. A small forest staff has now been appointed, and plans are being formed for the establishment of a school for training forest assistants.

France.—The principal timber tree of France is the oak, and various species are much cultivated. The cork oak is grown extensively in the south and in Corsica. The beech, ash, elm, maple, birch, walnut, and poplar are all important trees, while the silver fir and spruce form magnificent forests in the Vosges and Jura Mountains, and the Aleppo and maritime pines are cultivated in the south and south-west. About one-seventh of the entire territory is still covered with wood.

Forest legislation took its rise in France about the middle of the 16th century, and the great minister Sully urged the enforcement of restrictive forest laws. In 1669 a fixed treatment of state forests was enacted, and in 1750 Mirabeau estimated the woodlands in France at 70 millions hectares. Duhamel in 1755 published his famous work on forest trees. Reckless destruction of the forests, however, was in progress, and the Revolution of 1789 gave a fresh stimulus to the work of devastation. The usual results have followed in the frequency and destructiveness of floods, which have washed away the soil from the hill sides and valleys of many districts, especially in the south, and the frequent inundations of the last fifty years are no doubt caused by the deforesting of the sources of the Rhone and Saone. Laws were passed in 1860 and 1864, providing for the reforesting, "reboisement," of the slopes of mountains, and these laws take effect on private as well as state property. Beneficial results have already ensued. Thousands of acres are annually planted in the departments of Hautes and Basses Alps; and during the summer of 1875, when much injury was done by floods in the south of France, the Durance, formerly the most dangerous in this respect of French rivers, gave little cause for anxiety, and it is round the head waters of this river that the chief plantations have been formed. While tracts formerly covered with wood have been replanted, plantations have been formed on the white shifting sands or dunes along the coast of Gascony. A forest of *Pinus Pinaster*, 150 miles in length and from 2 to 6 broad, now stretches from Bayonne to the mouth of the Gironde, raised by means of sowing steadily continued since 1789; and the cultivation of the same pine in the department of Landes has, along with draining, transformed low marshy grounds into productive soil. With the provinces of Alsace and Lorraine, a large extent of forest was ceded to Germany in 1871.

An official report, dated 1872, gives the following forest areas:—

State forests	900,000	hectares.
Communal forests	2,000,000	"
Private forests	6,000,000	"
Total	8,900,000	hectares.

In 1877 the French state forests contained 985,086 hectares, and the communal 1,919,622 hectares. The revenue in 1827 amounted to 27,000,000 francs, three-fourths of which was from the sale of timber, and one-fourth from other forest produce. The estimated revenue for 1877 was 38,500,000 francs, 29,500,000 of which was to come from the regular fellings, and the remainder from extraordinary cuttings and minor forest produce. The annual expenses of the forest department average 13,000,000 francs. For 1877 the actual figures were 13,325,732 francs, of which about 5,000,000 is for the pay of the establishment, two and a half millions for roads, two for plantations, and the balance for conservancy and management.

The department is administered by the director general, who has his headquarters at Paris, assisted by a board of administration, who meet twice a week, and are charged with the working of the forests, questions of rights and law, finance, and plantation works. The establishment consists of 36 conservators, 174 inspectors, 310 sub-inspectors, and about 420 *gardes généraux*, the number being regulated by the exigences of the service.

The department is supplied with officers from the forest school at Nancy. This institution was founded in 1824, when M. Lorentz, who had studied forestry in Germany, was appointed its first director. Any French youth from eighteen to twenty years of age may compete for admission to the school on producing certain certificates and filing a bond guaranteeing the payment of 1500 francs a year, and 600 francs from the date of his joining the establishment till he is promoted *garde général* on full pay. The entrance examination comprises arithmetic, algebra, geometry, trigonometry, physical sciences, chemistry, plan-drawing, mechanics, German, history, geography, and free-hand drawing. The pupils pass two years in the school, and during a third attend lectures, while taking practical charge of portions of forest near Nancy. The school is under a director, a sub-director, and eight professors, besides two officers for military instruction. In the winter session eight hours daily are spent in the school, and the summer term is chiefly passed in forest tours, the pupils accompanying the professors, who apply the teaching of the school to objects found in the forest. There are usually 45 to 50 French pupils. The French Government has kindly extended the benefits of this well-equipped institution to candidates for employment in the state forests of British India.

Switzerland.—Forests in Switzerland cover about 18 per cent., or one-sixth of the whole area, but in some of the cantons excessive deforesting has taken place. On the precipitous mountain sides the forest is found to have a powerful influence in preventing the formation and descent of avalanches, and in the Alps the woods are preserved, though insufficiently, by law. A distinguishing feature of Swiss forests is the prevalence of the silver fir, *Abies pectinata*, which covers large tracts on the mountains up to 4000 feet; the larch is sometimes mixed with beech to 3000 feet, more rarely with oak and walnut to 1800 feet, and chestnut to 750 feet. Each canton regulates the management of forests within its own limits; but efforts repeatedly made in the Federal Council for the introduction of a uniform system of forest legislation throughout the republic have not yet been successful.

Vigorous attempts to preserve and restore wooded land are made in some of the cantons, and difficulties in the transport of timber from inaccessible points have been skilfully overcome by the ingenious adaptation of wooden tramways and iron rope slips.

Italy.—The kingdom of Italy comprises such different climates that within its limits we find the birch and pines of northern Europe, and the olive, fig, manna-ash, and palm of more southern latitudes. The ascertained extent of wood in 1872, including the wooded island of Sardinia, was, according to Siemoni, 5,025,893 hectares, or about 17·63 per cent. of the entire kingdom, a proportion which might with advantage be greatly increased, but in the latest return it has fallen to 12·34. By the republic of Venice and the duchy of Genoa forestal legislation was attempted at various periods from the 15th century downwards. These efforts were not successful, as the Governments were lax in enforcing the laws. In 1789 Pius VI. issued regulations prohibiting felling without license, and later orders were published by his successors in the Pontifical States. In Lombardy the woods, which fifty years ago reached nearly down to Milan, have almost disappeared. The province of Como contains only a remnant of the primitive forests, and the same may also be said of the southern slopes of Tyrol. At Ravenna there is still a large forest of stone pine, *Pinus Pinea*, though it has been reduced to a third of its former extent. The plains of Tuscany are adorned with planted trees, the olive, mulberry, fig, and almond. Sardinia is rich in woods, which cover one fifth of the area, and contain a large amount of oak, *Quercus Suber*, *Robur*, and *Cerris*. In Sicily the forests have been long felled save the zone at the base of Mount Etna.

The destruction of woods has been gradual but persistent; in the end of the 17th century the effects of denudation were first felt in the destructive force given to mountain torrents by the deforesting of the Apennines, and up to the present time the work of demolition continues. According to the statistics published by the Italian Government in 1870, there were 215,801 hectares of state forest, including woods attached to royal residences; but by the sale, alienation, or destruction of the greater part, the area has since been very greatly reduced. Of communal and private forests the extent is, according to Government statistics,

	1870.	1877.
Communal forests	2,169,914 hectares	1,580,000 hectares.
Private forests	2,662,178 "	2,040,401 "

Only about 1,500,000 hectares are really covered with timber, as these figures include land with mere coppice or brushwood.

In 1867 the monastic property of Vallombrosa, Tuscany, 30 miles from Florence, was purchased by Government for the purposes of a forest academy, which was opened in 1869, and energetic measures were initiated throughout the kingdom for the preservation of the remaining woods. It is to be regretted that, by a change of policy, the area of forest has now greatly decreased. The administrative staff consists of 3 inspectors general, 35 forest inspectors, and about 300 subordinate officials. The royal forest school at Vallombrosa is surrounded by a splendid forest of silver fir, and a large extent of broad-leaved chestnut, beech, and other trees is also attached to it. *Pinus halepensis* and *Pinea* and larch are the other prevailing conifers. The number of pupils is about 60, and the course of study resembles that at Nancy. A forest periodical is regularly published at Florence. Director di Berenger, who has superintended the school from its foundation, is a man of great learning, and author of several important works on forestry.

Spain and Portugal are very deficient in woodland. The Peninsula is not unsuited to the growth of timber, as evinced by the noble forests which existed in the times of the Moors, especially in the southern provinces. There was a code of forest laws in Spain in the reign of Philip II., but it seems never to have been carried out, and the fine forests have long since disappeared. The evils of denudation are perhaps nowhere more signally exemplified than in Spain, and "Rentzsch even goes so far as to ascribe the political decadence of Spain wholly to the destruction of the forests" (Marsh, p. 306). Although her physical conditions render a large extent of forest almost indispensable to industrial progress, Spain may be said to be the only European country, with perhaps the exception of Great Britain, in which there has been no provision for the protection of woods.

The evergreen oak (*Quercus Ilex*), and its congener the cork oak (*Quercus Suber*), are found associated with *Pinus Pinaster*. "The Sierra de las Albujarras, southward of the city of Granada, is clothed with fir woods up to the peaks on certain places, so that the existing forests would appear to be the remnants of a destroyed girdle of coniferous trees, formerly covering all these chains. In the fluviatile valleys of the Sierra Nevada isolated groups of trees present themselves, the wrecks of larger woods" (Henfrey, p. 295). In central Spain and on the slopes of the Pyrenees there are still considerable tracts covered with *Pinus Laricio*, *P. pyrenaica*, and *P. halepensis*, while on the northern coast *Pinus Pinaster* abounds. The sweet chestnut, indigenous in Spain, forms forests more or less cultivated for the sake of its fruit, which is an important article of food.

A forest school has been lately established in the Escorial, and good results from the training there may be hoped for.

The proportion of woodland in Portugal is nearly the same as that of Spain; but a system of management is in operation under an administrator-general of forests. There are three forest zones characterized by the pine, the evergreen oak, and the deciduous oak. *Pinus Pinaster* abounds on the coast, giving place south of Lisbon to *P. Pinea*, the stone pine. The largest forest is that of Leiria, composed chiefly of the maritime pine, *Pinus Pinaster*; and adjoining the forest are establishments for the preparation of tar and resin, and the impregnation of wood.

ASIA.[1]

India.—The forests of British India are of great extent and value. Under the rule of Hindu and Mahometan princes, as well as in the earlier years of British domination, the forests were recklessly injured by felling, or by the recurrence of destructive fires, thereby deteriorating the climate and impoverishing the people. But conservancy has been introduced in time to preserve many of the advantages they are calculated to afford, to make them a considerable source of revenue to the state, and to provide for the needs of future generations. The change from uncontrolled waste to careful state supervision is necessarily slow: immemorial usages have to be overcome, and many obstructions to be removed, before the department is in good working order; great progress has, however, been made. The forest department is now a branch of the public service, for which candidates are annually selected by the Secretary of State for India.

Attention was first directed to conservation in India by the appointment of a committee by the British Association in Edinburgh in 1850, to consider the "probable effects, in an economical and physical point of view, of the destruction of tropical forests;" and a report was printed in 1851, showing the importance of preserving every influence which tends to maintain an equilibrium of temperature and humidity, of preventing the waste of valuable material, and the special application to their various uses of the indigenous timbers of the country. Indian botanists, to their credit, had long urged on the Government the necessity of stopping the waste of valuable timber. Advancing civilization, the progress of agriculture, and the rapid extension of railways soon rendered it imperative that means should be taken to organize a general system of forest administration, to control the clearing of indigenous forests, and to economize public property for the public good. About 1855 the first attempts at organization were made, the executive arrangements being left to the local administrations. In Bombay, Burmah, and Madras, conservators were appointed who started as it were single-handed and without skilled assistance, depending on such help as could be found in the local services. After the mutiny of 1857 a staff of five or six assistants was sanctioned in each of these provinces, the more valuable forests were mapped out, and exact information was obtained regarding their resources. In 1862 the Government of India organized a departmental system of conservancy for the whole empire, and the office of inspector general of forests was created. A Forest Act, No. 4 of 1864, gave power to local administrations to demarcate the limits of state forests, and to reserve certain trees for state purposes, and notified the mode of procedure in cases of damage, conflagration, etc.; and in October, 1877, the report of a select committee on a bill to amend the law relating to the preservation of state forests was under the consideration of the Indian Government. Many of the forest officers first appointed were chosen because of local knowledge and love for natural history rather than their knowledge of practical forestry, but with these extended operations the want of trained assistants soon became apparent. It was therefore determined to train young men specially for the work, and as forestry is in France a branch of Government service, advantage is taken of the forest school at Nancy in France, and five or six youths, after having passed through the usual course of study there, both theoretical and practical, are annually sent to India. In 1876 the officers of the higher grades had increased to 147,—1 inspector general, 10 conservators of provinces, 136 deputies and assistants. The post of inspector general is held by Dr. Dietrich Brandis, to whose energy and experience is in great measure due the success which has attended the progress of the department.

Many large and valuable tracts of forest are in the territories of native chiefs; and to prevent these being wholly destroyed, the British Government leases them for a long term of years, paying an annual rent, or a seigniorage on each tree felled. Throughout the empire the forest lands are burdened with grazing and other village rights, and it has required much tact to effect the formation of forest reserves to their present extent. As opportunity offers, unreserved forests are added to the reserves. The following figures embrace all the provinces under the Government of India (excluding Madras and Bombay). In 1875–6 the area of reserved and leased forests was 15,089 square miles, being an increase of 3000 square miles during the year. The aggregate area of plantations is about 26,000 acres, and the trees cultivated in the different provinces are as follows:—

Bengal	Toon and Teak.
North-West Provinces	Deodar, Walnut and Horse-chestnut.
Punjab	Deodar, Sissu, Kikar, Ber, and Mulberry.
Burmah	Teak.
Assam	Caoutchouc.
Madras	Teak, Red Sanderswood, Casuarina, Eucalyptus.
Coorg and Mysore	Teak and Sandalwood.
Berar	Teak and Babool.
Oudh	Sal.

The most important articles of export are teak, sandalwood, cutch, caoutchouc, and lac, the last chiefly from the Central Provinces. In 1875–6 the following amounts were exported from India:—

	Tons.	Prices per Ton.
Caoutchouc	763	1282 rupees.
Shell-lac	4,032	1613 "
Lac-Dye	533	500 "
Sandalwood	500	500 "
Cutch (Catechu)	9,762	173 "
Myrobalans	14,317	74 "
Teak (50 cubic feet)	60,656	73 "

---

[1] A very comprehensive view of the geographic botany of the Asiatic continent and the distribution of its flora will be found in the article ASIA.

The export of teak commenced about 1829, after the annexation of Tenasserim, and at first it was only from British territory. In 1835 teak began to come from beyond the frontier in largely increasing quantities. After the annexation of Pegu forest operations in British territory were regulated, and the average export to Indian and foreign ports from 1856 to 1862 was 20,000 tons, four times that amount coming from beyond the frontier. Nearly two-thirds of the teak goes to Calcutta, Madras, and Bombay, and the rest to Britain. The finest teak plantation is the Conolly plantation in Malabar on the Beypur River (Madras Presidency), where the rainfall is 150 inches annually. It now covers about 4000 acres, and 100 acres are added every year. The result has been most satisfactory, in the provision of an immense stock of valuable material, and the outlay incurred is being gradually recouped.

Cutch, the extract of the heartwood of *Acacia Catechu*, comes chiefly from Burmah, partly from Mysore and Malabar. It is used for tanning and dyeing. Lac is chiefly produced in Central India; the collection is expensive, but the quantity may be still further increased. *Butea frondosa* and *Schleichera trijuga* are the chief lac-yielding trees. Caoutchouc, the produce of *Ficus elastica*, is collected in Assam and Sikkim, and latterly also in Burmah, where, however, the tree is not indigenous. Most of the sandalwood of commerce (*Santalum album*) is from Mysore and Coorg, and is exported from Bombay. In Mysore more than half of the forest revenue is derived from this tree.

The surplus forest revenue from the different provinces for 1875–6 was as follows:—

The Presidency of Bengal	22,86,840	rupees.
Madras.....(deficiency	3,724)	"
Bombay	4,70,195	"
	27,53,311	rupees.
Native States Administered.		
Mysore	15,257	rupees.
Berar	1,41,943	"
Total	29,10,511	rupees, or £291,051.

Much expenditure is needful for improving the roads through the forests, and for the blasting of rocks in rivers, which, both in the plains and in the Himalaya, are much used for floating logs. Fuel plantations on a large scale, especially in Madras and the Punjab, have been formed for the supply of railways and steamboats; the demarcation of forests is steadily carried on, the reserves are mapped, and laws are in force for the exclusion of cattle from the reserves and for the prevention of fires; waste has been prohibited, and in many ways a gradual improvement is taking place. New species of trees of rapid growth are being acclimatized. "From Australia several kinds of *Eucalyptus* and *Acacia* were introduced about twenty-five years ago, and they have made such progress that the station of Ootacamund is now almost surrounded by a forest of these trees. Their rate of growth is wonderfully fast, much faster than that of the indigenous trees. Young forests of the quinine-yielding *Cinchonas* are coming up in many places. The management of these cinchona woods will probably be similar to the treatment of oak coppice in England; for though oak bark has not one-twentieth the value of Jesuit's bark, it is the bark in both cases for which these woods are mainly cultivated. There will, however, be the difference that while oak coppice in Europe, after having been cut over, requires from fourteen to twenty years to yield another crop of bark, cinchonas grow so rapidly that they may probably be cut over every eighth or tenth year." It has been decided to establish a forest school in North India for training candidates for the executive branches of service, and to attach to it a large area of reserved forest.

The teak, *Tectona grandis*, may be called the king of Indian timber trees; it is prized for shipbuilding beyond any other wood, and is specially valuable for works in contact with iron. It is indigenous in Hindustan as well as in Burmah and the neighboring states, generally growing in company with bamboos and other trees in dry deciduous woods. It grows to perfection in Malabar and West Burmah, where the rainfall is heaviest. The northern limit is about 25° N. lat. The sal, *Shorea robusta*, another most important tree, forms extensive pure forests along the base of the Himalaya, from Assam to the Sutlej, and in the eastern part of Central India. It yields a heavy durable timber, in great demand for building, gun carriages, and railway sleepers. The deodar, *Cedrus Deodara*, is to North India what teak is to Madras, Bombay, and Burmah, and what sal is to Bengal and the great Ganges Doab. It is indigenous in the north-west Himalaya and the mountains of Afghanistan, and forms extensive forests in the basins of the Indus, Tonse, Jumna, and Bhagirati rivers. Black wood (*Dalbergia latifolia*) and sissu (*Dalbergia Sissu*), toon (*Cedrela Toona*), satin wood (*Chloroxylon Swietenia*), sandalwood (*Santalum album*), red sanderswood (*Pterocarpus santalinus*), and the various kinds of ebony (*Diospyros*) are amongst the most important of the many valuable woods of India.

Official Reports on Forest Conservancy (4 vols. folio), showing the progress of departmental administration in India from 1862 to 1871, issued among parliamentary papers, contain much statistical and practical information. The advance of forest management in India has led to the publication of three useful handbooks:—(1) *The Flora Sylvatica of South India*, by Col. R. H. Beddome, Madras, 1873; (2) the admirable *Forest Flora of North-West and Central India*, by Dr. Brandis, London, 1874; and (3) *The Forest Flora of British Burmah*, by the late Sulpiz Kurz, Calcutta, 1877. The systematic working of the forests has also been facilitated by the publication of a code for the transaction of forest business. There is an annual conference of forest officers, when questions of principle and practice are discussed; and a quarterly magazine of forestry—*The Indian Forester*—published in Calcutta, has been established for the record of observations and experiments. For a classified list of trees with vernacular names and local uses, see the works cited, and the jury reports of the Madras and Punjab Exhibitions; Cleghorn's *Forests and Gardens of South India*, 1861; Drury's *Useful Plants of India*, 1873; Dalzell's *Bombay Flora*, 1861; and Stewart's *Punjab Plants*, 1869.

Ceylon.—The coast of Ceylon is fringed with the cocoa palm; the betel palm, talipat, and palmyra also abound, the last in the north of the island, while the interior is richly wooded, having ebony, calamander, satinwood, and 30 or 40 varieties of timber valued for construction and shipbuilding, but no teak. Forest reserves are being formed. (See *Enumeratio Plantarum Zeylaniæ*, Thwaites, 1864.)

Siam.—The forests of Siam contain a large amount of teak, some of which has been exported. Other principal trees are gamboge (*Garcinia*), gutta-percha (*Isonandra*), eagle wood (*Aquilaria Agallocha*), ratans, durian, mangosteen (*Garcinia Mangostana*), and several valuable palms, as the sago (*Sagus farinifera*).

Borneo is remarkable for its luxuriant vegetation, and the extensive forests produce ironwood, gutta-percha, ebony, sandalwood, ratans, sapanwood, gambir, dragon-blood, sago palm, and the mast (*Calophyllum*) and camphor trees (*Dryabalonops*).

China.—The forest area of the great empire of China is little known, especially in the northern half, which resembles Japan. In the west there are large forests containing ebony, sandalwood, camphor tree, tallow tree (*Stillingia sebifera*), mulberry, paper-mulberry (*Broussonetia papyrifera*), varnish tree, funeral cypress. The mountain regions of the islands of Formosa and Hainau are well wooded. From Formosa we obtain most of our supply of the camphor of commerce. (See Fortune's *China*, and Bentham's *Flora Hong-kongensis*.)

Japan is well wooded, and the arboreal flora presents a remarkable combination of sub-tropical and temperate forms,—the tree-fern, bamboo, banana, and palm growing with the pine, the oak, the beech, and Coniferæ in great variety. The evergreen oaks and the maples are the finest of all Japan trees, whilst the *Rhus vernicifera* or lacquer tree, *R. succedanea* or vegetable-wax tree, *Laurus camphora* or camphor tree, and paper-mulberry are among the remarkable or characteristic trees of the country. (Siebold and Zuccarini's *Flora Japonica*.)

Siberia possesses immense tracts of forest, particularly in the neighborhood of Tobolsk, Tomsk, and Ekaterinburg. Pines, larch, cedar, and birch are the principal trees on the mountains north of the great steppes and marshy plains. The northern limit of the pine is about 70°. Willows, alders, and poplars are used for fuel on the plains. Elms and wild apricots are mentioned by travellers, but the oak is not indigenous. It is estimated that Siberia contains 2,000,000 acres of forest in the districts above named. The vast plateau of Tartary and Tibet is of great sterility, dry, and almost treeless, and the climate is very unpropitious. In Manchuria there are extensive coniferous forests, and on the east coast there is said to be oak on the mountains, while on the low land the maple, willow, apricot, and mulberry are found.

AMERICA.

America is of all quarters of the world the most thickly wooded with primeval forest. The territory on the north-west coast and islands is well stocked with pine timber.

Canada.—The forests of British North America are of the first importance for the comfort and welfare of its people, as no coal is found in the centre of the Canadian Dominion. Canada contained immense forests, which are still extensive, chiefly of black and white spruce, the Weymouth (*Pinus Strobus*) and other pines, which grow to a great height and do not admit of undergrowth. The dark and sombre forests are also rich in other commercial woods, such as oaks, ash, maple, hickory, and walnut. The export of timber is very great, and Great Britain draws more from Canada than from any other country. *Pinus Strobus* yields the largest amount, and is the most valuable of Canadian woods. It is now chiefly obtained from the head waters of tributaries of the St. Lawrence. The extensive lumber trade is causing rapid denudation. Tracts of land are let to "Lumber Companies," whose object is to get as large a return as possible, and annually thousands of acres are destroyed by fire. An Act has recently been passed regarding the public lands of the Dominion, which provides for the care of young trees; and in Quebec it is no longer permitted to cut pine trees less than 1 foot diameter at the stump. It has also been proposed to establish a school of forestry.

United States.—The primitive forests of America were of immense extent, and contained a remarkable diversity of species, covering in the 17th century, with insignificant exceptions, all that portion of the North American continent which has been occupied by British colonists, and apparently adequate to the exigences of advancing settlements to an indefinite future; but now, it is "doubtful if any American State, except perhaps Oregon, has more woodland than it ought permanently to preserve" (Marsh, p. 326). About 40 species of oak are indigenous in America, 16 conifers, several maples, birch, ash, beech, elm, hornbeam, hickory, poplar, magnolia, walnut, butternut, etc. The eastern and midland States were at one time dense forests; now, Pennsylvania alone excepted, these are denuded of the pines and other commercial woods, and are compelled to draw much of their supply from Canada and the West. Even the forests in Pennsylvania, which once yielded the finest pines in America, are now greatly reduced in extent and value. The earliest restrictive measure of Government was adopted in 1817, when oak and red cedar were reserved; and a law was passed in 1831 to arrest spoliation. The enormous supplies of timber still brought to market may be judged of from the fact that the number of saw-mills in 1870 was 25,817—an increase of over 6000 in ten years. Fortunately public opinion has been aroused, and a Forestry Association has been formed, to show the vast annual decrease of forests, and the urgent necessity of planting to a large extent. In Massachusetts valuable prizes are offered for planting white ash and white pine, spruce and larch, with a view to the raising of useful timber, and affording the needed shelter to the crops. In 1858 a premium of 1000 dollars was offered for the best plantation of forest trees planted in 1860, payable in 1870. The States of Illinois, Missouri, and Iowa have also encouraged tree-planting by State laws. Further west, in the prairie regions, energetic measures are being adopted to create woodlands on hitherto treeless plains. In Nebraska ash, walnut, and elm are largely planted, and along the Central Pacific Railway belts of Australian gum and other trees are being formed to protect the line from snow drifts, and for a future supply of timber. In the State of California a forester has been appointed, and legal provision made to render the discharge of his duties effectual. By a law of California, dated 30th March, 1868, the board of supervisors in each county are empowered to authorize owners of lands to plant and cultivate, along the public highways, shade and fruit trees, specifying the species to be planted, at what age, at what distance from each other and from the road bed, and making the necessary rules for their protection, etc. Four years after the planting, upon receiving a duly certified statement of the number then in a good condition, the board are directed to pay to the cultivator one dollar for each such tree. California still possesses her magnificent Sequoias, *S. gigantea*, which attain when full grown an average height of 275 feet, and a girth of 70 feet at 6 feet from the ground. Sir J. D. Hooker tells of a forest forty miles long, and 3 to 10 broad, in the Sierra Nevada, where alone the tree is indigenous. Wood-cutters and saw-mills are, however, busy at work, converting the valuable Sequoias into marketable timber, and sheep grazing and fires kindled by the lumbermen are effectually destroying the saplings. Hooker writes in 1878—"The devastation of the Californian forest is proceeding at a rate which is utterly incredible, except to an eye-witness. It is true that a few of the most insignificant groves of the big trees at the northern extreme of its range are protected by the State legislature, and a law has been enacted forbidding the felling of trees over 15 feet in diameter; but there is no law to prevent the cutting or burning of the saplings, on which the perpetuation of the grove depends, or to prevent the burning of the old trees, which, if they do escape the fire, will succumb to the drought which the sweeping away of the environing forest will occasion." In Texas, where there is a very inadequate supply of timber, the growth of trees on the prairies is being attempted, but the frequency and destructiveness of prairie fires are great obstacles to success.

Central America.—Mexico and the various states of the isthmus uniting North and South America, as well as the West Indian Islands, possess abundant forests, which are as yet, however, imperfectly known. But they contain many fine timbers in large quantities, the chief of which, mahogany, *Swietenia Mahagoni*, deserves special notice. The mahogany tree is found on the mainland and in the West Indian Islands between 11° and 20° N. lat. It grows to a large size, with a perfectly straight stem, and is exported from the different states and islands where it grows. That which comes from British Honduras is esteemed the best, but the supply from there has declined of late years. Mahogany was first imported into England about 1640. It has been introduced into Bengal and Malabar. In the neighborhood of Panama 2000 persons are employed in drawing off the juice of *Castilloa elastica*, the Central American caoutchouc tree, and in Nicaragua 600 to 800 persons find similar employment. (See *Nature*, 1875.)

Cuba.—For variety and value the woods of Cuba rival those of the mainland, but the Government forests have been neglected and left to chance and plunder. There has been no attempt to control the misuse, waste, and wanton destruction of forest. Valuable timber is felled for making enclosures, and much is burnt. Almost all the remaining woods belong to private persons. Mahogany, cedar, and fustic wood, with many others, are produced freely. During last century forty-two ships of war were built in the Royal Arsenal of Havana, and with proper management much timber for naval purposes might be obtained.

South America.—The richness and luxuriance of the tropical vegetation in South America are proverbial, and the whole chain of the Andes is clothed with wood, varying according to elevation, latitude, and aspect. Owing to the scarcity and high price of labor, with the few facilities of transport to the sea-coast, the timber trade of South America has not as yet reached great dimensions; but with the increase of population and the opening up of the country this commerce will be vastly developed. No data as to the extent of forest area are available, but with great variety of climate in the vast continent there is great diversity also in the vegetation. Each state has its own special forest-products to export, of which, however, we can only name a few of the more valuable.

British Guiana furnishes two of the most valuable timbers known for shipbuilding, greenheart (*Nectandra Rodiæi*) and mora (*Mora excelsa*); both of these grow to a large size, and are said to be very abundant, but owing to the great demand, and the want of legal restriction to prevent the cutting of saplings, it is becoming difficult to obtain good greenheart. It is to be hoped that the British colonies in the western hemisphere will follow the example of the East Indian empire, and introduce, ere it be too late, measures of conservancy and reproduction. Sir J. Hooker has urged this in strong terms. (*Kew Report*, 1877.)

French Guiana contains valuable forests, and produces "angelique" (*Dicorynia paraensis*), a timber much employed in naval dockyards.

Venezuela.—Humboldt mentions in his travels that the waters of the Lake Valencia had greatly decreased owing to the clearings of forest in the Aragua valley, near the northern coast of Venezuela. The Orinoco, the great water highway of Venezuela, is fringed in its lower course with magnificent evergreen forests. The most important trees of this republic are lignum vitæ (*Zygophyllum arboreum*), found chiefly on the coast, and "guayacan," used for cabinet work. Brazil wood is so common as to be generally used for fences. Cedar and ebony are also among the products. Venezuela is the home of the cow tree (*Galactodendron utile*), which yields large quantities of nutritious thick milky juice. The cocoa plant (*Theobroma Cacao*) is also a native of the north of South America, thriving vigorously with a maximum of humidity and a high temperature.

Ecuador contains great forests east of the Andes, where the climate is excessively humid. The export trade in 1874 amounted to £676,635, upwards of £500,000 being for cocoa, india-rubber, and cinchona bark. The bark of *Cinchona Calisaya* is no longer procurable; that of *C. succirubra* is exported.

Brazil.—The great empire of Brazil has forests covering an area half the size of Europe. For 2000 miles the river Amazon flows through Brazilian territory, and forms with its tributaries the only interruption in a rich level tract measuring 1200 miles from E. to W. and 800 from N. to S. covered with virgin forest. R. Spruce graphically describes the wonderful luxuriance of a forest on the Amazon.

> "As we ran along shore and gradually lessened our distance, I endeavored to trace out the species composing the forest, but, with the exception of the palms, of the trees with bipinnate foliage, and of a few with remarkable dome-shaped crowns, there was such an intermingling of forms that I in vain attempted to separate them; nor was there, among exogenous trees, any contour so striking as the twisted pyramid of our northern pines. When I entered the forest the confusion was still greater; for so much were the branches of adjacent trees interwoven, and so densely veiled in many cases with twiners and epiphytes, that only an indistinct view could be obtained of any individual tree, and it was only when sailing along the banks of the rivers that I saw so much of the trees in the inundated forest as to give me a clear idea of the outlines and general aspect of many of them."—*Jour. Linn. Soc.*, v. 3.

The productiveness of the Brazilian forests may be inferred from the fact that in the Paris Exhibition of 1873 were 300 different kinds of timber, many of them of great value both for naval and civil construction and for ornamental work. No plantations have yet been formed of these valuable woods, and fustic and Brazil wood are to be met with only at a distance from the coast. The most important woods of construction are —jacaranda (*Dalbergia nigra*), Brazil wood (*Cæsalpinia echinata*), ironwood (*Cæsalpinia ferrea*), cedar (*Cedrela brasiliensis*). But the Brazilian forests though rich in timber are richer still in gums, resins, drugs, dyes, and produce valuable for trade and manufacturing purposes. The great development of commerce in forest produce is illustrated by the export returns for 1871–72, viz.:—

	Tons.	£.
Caoutchouc	4723	750,000
Maté (Paraguay Tea)	9357	227,581
Cocoa	3125	150,929
Rosewood	...	105,100
Manioc flour	6960	35,813

Of dye stuffs the best are Brazil wood, fustic (*Maclura tinctoria*), red mangrove (*Rhizophora*), arnotto (*Bixa Orellana*); of drugs, sarsaparilla (*Smilax* sp.), ipecacuanha (*Cephaelis Ipecacuanha*), guarana (*Paullinia sorbilis*), jalap (*Exogonium Purga*), etc. Europe draws from Brazil its largest supply of caoutchouc. It is obtained from *Siphonia elastica* and *Hancornia speciosa*, trees growing in abundance in the provinces of Amazonas and Para, and so large has been the export that in some districts the supply begins to fail. *Copernicia cerifera*, the wax palm, is a most valuable tree,—the estimated annual production in wax and fibre is nearly £250,000 (official return). Brazil wood and Brazil nuts (*Bertholletia excelsa*) are among the largest exports.

Peru.—In the Montana region of Peru (that is, the extensive area stretching eastward from the Andes to the confines of Brazil) are vast forests, yielding in spontaneous abundance Peruvian bark, india-rubber, vanilla, copaiba, cinnamon, sarsaparilla, ipecacuanha, vegetable wax, etc., but the collection of produce and its transport through the sierra and coast regions to the ports are attended with much difficulty and expense. The region of cinchona trees lies between 19° S. and 10° N. lat., and between 2500 and 9000 feet elevation above the sea. In South America the miserable Governments of the cinchona districts have almost destroyed the inestimable boon with which a bountiful Providence has endowed them. Happily, in this case, the energy of such men as Markham, Spruce, and others has in great measure prevented a loss which would have been incalculable; for the cinchona plantations established in India, in Java, and in various other colonies give promise that Europeans will not in the future suffer from the thoughtless greed of the semi-civilized Governments of the Andine States.

Chili.—In the inner valleys of the Cordilleras there are estimated to be from 250,000 to 500,000 acres of virgin forest, containing trees of great dimensions.

Uruguay.—The "montes" of South and Central Uruguay form narrow fringes to the larger streams, and rarely exceed a few hundred yards in width. Seen from distant higher ground they resemble rivers of verdure meandering through the bare campos, from which they are sharply defined—the reason being that the wood only grows where it is liable to inundation. N. and E. Uruguay are little known, but the same description is applicable to them. In the montes of the Rio Negro, Dr. David Christison reports having seen twenty species of trees and shrubs, including a palm which extends southwards to the Santa Lucia. The montes of Uruguay are of no commercial value, and their extent must be trifling, but they suffice for the wants of the present scanty population. The beautiful ombu (*Pircunia* or *Phytolacca dioica*) is the only tree which is possibly native on the campos. The softness of its spongy tissue renders it useless for burning and for timber. On the eastern side of South America, continued in the whole stretch of 1500 miles south of the Rio de la Plata to the straits of Magellan, wood seems to be extremely rare, except a few thorny acacias in the plains of Patagonia, some willows on the banks of one or two of the rivers, and the antarctic beech and the Winter's bark tree—a great contrast to some of the islands of Tierra del Fuego, which, from the descriptions of Darwin, we know to be completely covered with forest.

AUSTRALIA.

The large continent of Australia, so far as it has been colonized, is emphatically a pastoral country, and no survey has yet been made of its surface bearing wood. There are vast tracts in the interior covered with *scrub*, but the total area of forest producing timber seems to be comparatively small. The growth of trees is more vigorous in the east than on the north and north-west coasts. The foliage is usually evergreen, and the leaves of many trees hang vertically. The chief forests occupy the flat margins of the rivers, and are composed of species of *Acacia* and *Eucalyptus* mingled with *Callitris* and *Casuarina*, *Banksia*, *Melaleuca*, *Xanthorrhæa*, and *Exocarpus*. The *Eucalyptus* and *Acacia* are said to compose four-fifths of the forests of Australia and Tasmania. These trees, formerly despised and thought of little value, are now introduced into many countries where artificial planting has been found necessary, and are extensively grown in India, Mauritius, Algeria, and Italy. The Eucalypti in particular possess many excellent qualities: their timber is of great durability, strength, and toughness; they are rapid in growth; and *E. Globulus*, or blue gum, is reputed to purify the surrounding air from malaria, and is frequently found 300–350 feet high, while *E. diversicolor* attains still larger dimensions. These, along with *E. resinifera*, iron bark tree, and *E. marginata*, Australian mahogany, "jarrah," are reported to be abundant in many parts of Australia. Other principal trees, chiefly in the east, are *Cedrela Toona*, or red cedar, *Gmelina Leichardti*, *Araucaria Cunninghamii*, or the Moreton Bay pine, and *Castanospermum australe*, or Moreton Bay chestnut. In Western Australia, amongst other forest trees of note, are the raspberry-scented acacia (*A. acuminata*) and sandalwood (*Fusanus spicatus*). A simpler system of forest management than the elaborate organizations of France, Germany, or Scandinavia is applicable to thinly peopled colonies. In the province of Victoria a State Forest Board was appointed in 1867, and maps have been prepared showing the distribution of the principal trees within its bounds, the proposed reserves, and the forest ranges. A Planting Encouragement Act was passed in 1872. By the formation of the board, with an inspector of forests to aid by advice, provision has been made for the preservation of existing woods and young plantations. The first annual report appeared in 1875, from which we find that the total area of reserves is 1805 square miles, estimated to contain 400,000 trees, yielding an average of 700 superficial feet. There is a large state nursery, and there has been great success in planting exotic trees, *Abies Douglasii*, *Cedrus Deodara*, *Sequoia gigantea*, *Cupressus torulosa*, etc. These measures have been introduced mainly by the energy of Baron von Müller, the Government botanist in Victoria. Attention is directed to the subject in other Australian colonies, where there is an equal call for action, and a beginning towards conservation has already been made in Queensland. Even firewood in some places is now scarce; and the demands for mining and various industrial pursuits render it needful to import timber from other countries.

South Australia.—Dr. R. Schomburgk reports in 1878 that three valuable forest trees have been successfully introduced, and are recommended to the forest board:—(1) the American ash, *Fraxinus Americana*, which has been largely grown in the forest reserves; (2) English elm, *Ulmus campestris*; and (3) the plane tree, *Platanus orientalis*. With regard to replanting the country with roadside trees and clumps, the individual enterprise of farmers, agriculturists, and landowners must be looked to.

In *Tasmania* the arboreous forms are similar to those of Australia. Eucalypti are even more abundant, and the acaciæ begin to disappear. It is remarkable that these two genera should be wholly absent in New Zealand. The vast forests of Western Tasmania are extensively utilized for timber. (See Bentham and Müller's *Flora of Australia* and Hooker's *Flora of Tasmania*.)

New Zealand.—One of the richest portions of the globe as regards arboreous vegetation is the colony of New Zealand. It enjoys a climate similar to that of the south of Europe; the vegetation is most luxuriant, and many tropical plants flourish, while conifers, characteristic of colder regions, also abound. In Britain the number of indigenous timber trees is only 35 out of a flora of 1400 species, while New Zealand has 113 timber trees in a flora of only about 1000 species. The most valuable tree of New Zealand is the kauri (*Dammara australis*), which grows only in the northern island. It attains the height of 120–160 feet and is 5–12 feet in diameter, is unrivalled for masts, and has long been exported to British dockyards for that purpose. The value for 7 years ending December, 1873, from Auckland of kauri alone amounted to £144,000, against £19,739 of all other timber. Besides timber, kauri resin, obtained in great masses, is exported. In ten years the value amounted to £1,171,949; the price varies from £33 to £39 per ton. Other valuable trees are totara (*Podocarpus totara*) and matai (*P. spicata*), both found throughout the colony, and, like the kauri, yielding timber of great durability and strength, and *Vitex littoralis*, or New Zealand teak, esteemed more lasting than any other native wood. There are several species of *Fagus*, forming beech forest, and many other trees yield valuable wood, as *Leptospermum ericoides*, the tea-tree, and *Santalum Cunninghamii*, sandalwood. The forest area in New Zealand was calculated to have been 20,370,000 acres in 1830, and 12,130,000 acres in 1873, by Dr. Hector. The public were permitted to fell in the forests on payment of a small license fee, and reckless unchecked felling has been the consequence. Such rapid deforesting of these densely wooded islands has naturally created an alarm in the legislature, and the Government in 1872 passed a Forest Planting Encouragement Act, offering a bonus for land cropped with trees. Several large plantations have been formed, and the Government has shown itself awake to the importance of the subject. In 1876 Captain Campbell Walker, an experienced officer of the Indian forest service, was requested to examine the resources of the New Zealand forests, and to propose a scheme of working them. His report was presented to both Houses of Assembly in 1877, and deserves the earnest attention of the New Zealand Government. In this richly wooded country clearings have been made with rapidity, and the great work now must be to preserve and propagate the valuable indigenous trees. An idea of the vastness of forest operations in New Zealand is derived from the fact that there are 125 steam or water-power saw-mills at work, turning out 103,039,037 superficial feet in 1876, and from each of these mills a tramway is laid down penetrating into the forests; the rails are generally of wood, and the haulage is by horses. It is understood that large forest tracts are to be demarcated and placed under the control of Government officers. In this way only can a regular system of forest management be carried out, and the temptation to obtain quick returns by sale of valuable forest avoided.

Africa.

A large extent of the continent of Africa is arid and treeless; the drought in the desert is so great that no tree can resist it. But many parts are now ascertained to be rich in wood, and recent discoveries by Baker, Livingstone, Cameron, and Stanley have opened up vast regions where much beautiful timber abounds. The Atlas Mountains are covered with magnificent forests, containing eight species of oak, *Pistacia*, *Acacia arabica*, *Cedrus atlantica*, closely allied to if not the same species as *C. Libani* and *Deodara*, and many other trees. To the south of the Atlas, on the borders of the great Sahara, are large tracts covered with date palms. The Sudan region has few trees; among these are the baobab (*Adansonia*), tamarind, sycamore, fig, the doom and oil palms, with a few thorny acacias.

Algeria.—The forests consist mainly of the Aleppo pine (*Pinus halepensis*), the cork oak (*Quercus Suber*), *Q. Ilex*, the Atlas cedar (*Cedrus atlantica*), and the Atlas cypress (*Callitris quadrivalvis*); associated with these are the *Quercus castaneæfolia*, *Q. ballota*, *Pinus Pinaster*, and other species. The forest area is thus distributed:—state forests, 4,657,567 acres; communal forests, 191,487; total, 4,849,054 acres. About two-thirds of this area is under the management of the forest service, the rest having been granted on long leases for cork production or olive culture. Cork is one of the most valuable of Algerian products, each tree yielding six to eight francs' worth at a stripping. A large amount of bark for tanning and 50,000 tons of alpha grass are exported from the province. Conservancy has not yet proved remunerative, but with the extension of railroads an increase of revenue is expected (Major Seaton). The consul-general for Algeria alludes in the following terms to the evils which have attended the deforesting of Tunis:—

> "Nothing is more certain than that forests and tracts of brushwood not only prevent the evaporation of moisture by protecting the surface of the earth from the sun's rays, but they serve to retain the light clouds which otherwise would be dissipated, until they attain sufficient consistence to descend in rain or refreshing mists. A hill side deprived of the forest whose foliage acted as a huge parasol to the ground, and whose roots served to retain the vegetable soil which was formed by its decay, very soon loses the power of generating vegetable life at all. The rich mould gets washed by winter rains into the valleys; in the summer months the sand is blown down on the top of this; succeeding rains carry down stones and gravel, till very soon all the most fertile portions of the soil disappear, leaving a residuum which is only capable of supporting vegetation when it becomes fertilized by an exceptional amount of moisture, which, as time progresses, must become rarer and rarer, like the efforts of the spendthrift to live off income, and spending every year a portion of his capital."—Colonel R. L. Playfair, *Travels in the Footsteps of Bruce in Algeria and Tunis* (1877, p. 155).

Tunis.—The African traveller Bruce 110 years ago alluded to the forests through which he passed, where not a tree is now to be seen. Dr. Shaw and Desfontaines the botanist mention the Aleppo pine and the making of pitch, but the wide plain over which they journeyed is now treeless, and the forest described by the latter in 1784 has quite disappeared.

Egypt, though possessing no forests, has a considerable amount of wood in acacia, lebbek, tamarisks, tamarinds, zizyphus, etc., and has also a rich property in its date palms, which grow in great abundance.

Abyssinia has extensive woods in the mountains, whence the coffee plant has spread over the world.

The tropical vegetation of Africa under the equatorial belt of rain is very luxuriant, and differs much on the two coasts. In the interior of Central Africa, Livingstone, Cameron, and Stanley tell us of vast tracts of primeval forest in the Manyuema country between Tanganyika and the coast, and also in Urungu south of Tanganyika, but as yet little is known of them in detail. The explorations of Nachtigal have shed much light on the regions adjoining Bornu, and Rohlfs describes gigantic tamarind, acacia, and komova trees. Stanley writes in glowing terms of the dense growth of lofty forests through which he had to cut his way, and specially refers to *Bassia Parkii*, or shea butter, which attains a large size, *Oldfieldia africana*, or African teak, kola nut (*Sterculia*), cashew nut, and gigantic tamarinds.

The western coast states—Congo, Sierra Leone, Senegambia—are all rich in wood, but comparatively little is known of the amount or of the value of the timbers, though some of these already find their way into European markets, in small quantities, viz., barwood or camwood (*Baphia nitida*), African mahogany (*Swietenia Senegalensis*), and African teak (*Oldfieldia africana*). The low-lying portions are malarious, where the mangroves and other swamp-loving trees abound. The baobab (*Adansonia digitata*), which grows also on the east coast and in Nubia, attains a large size, with a huge rapidly tapering trunk, and yields a strong fibre from the bark. From the compact green appearance of the foliage of a mass of baobab Cape de Verd is said to have received its name. The Guinea palm (*Elais guinensis*) abounds on the western coast, and England imports annually from Africa 10,000 tons of the palm oil. Valuable gums, as copal, etc., are also obtained from both the east and west coasts; and with the prospective opening up of Central Africa many valuable forest products will certainly come into commerce.

Ashantee may almost be described as one continuous forest, "composed of tall and massive trees, with creepers extending like cordage from one to another, and so matting the foliage together overhead that a green roof is formed almost impenetrable to the sun. Here and there are chinks and skylights through which the sun shoots in and falls upon the tree trunks and ground in gleams and splashes of crystal light. There is not much undergrowth, for that kind of vegetation cannot exist without sunshine, and in the virgin forest is always a kind of twilight" (Winwood Reade).

Lower Guinea.—Welwitsch describes forests extending 700 miles along the coast from the Congo to the Cunene River. These consist of *Diospyros*, *Cæsalpinieæ*, *Combretaceæ*, and *Celastrineæ*, the higher mountains behind being covered with extensive forests of the same families, with *Sterculiæ*, *Cynomatiæ*, and *Copaifera Mopane*, Benth. He saw ten miles exclusively covered with *Hyphæne cucifera*, Pers., and adds: "I conclude that these palm forests covered in past ages a great portion of the coast districts of Angola, where at present they only appear as dwarf bushes without stems, and never blossom." The only tree which braves the general dwindling is the *Adansonia*, which is seen in full splendor throughout the district. The export of gum copal from Benguela is about 1,600,000 lb. per annum. (*Jour. Linn. Soc.*, ix. 288.)

South Africa has suffered much from denudation, and according to the Colonial Botanists' reports many of its evil effects have followed, such as the frequent occurrence of sudden and destructive floods, and occasional droughts of extreme severity. But South Africa possesses a great variety of forest trees, yielding timber of great strength and beauty; they are, however, only found in mountain gorges and over a limited area. (Harvey and Sonder's *Flora Capensis.*)

Mauritius, with its insular position and humid climate, possessed a most luxuriant indigenous vegetation, reaching to the water's edge; but the aboriginal forests have disappeared, and the scarcity of wood for building and fuel has necessitated an annual outlay of £20,000 for imported timber. To supply the wants of the people, to provide shelter, and to improve the sanitary condition of the island, the local Government adopted measures some years ago for forming plantations on the higher elevations. The Australian eucalypti flourish well, and the planting around Port Louis has been attended with marked advantage to the town. (*Flora of Mauritius*, Baker.) Through the agency of fire and goats, supplemented by the rapid spread of introduced plants, the rich primitive forests of Rodriguez and St. Helena have likewise become extinct. (Hooker's *Insular Floras.*)

Madagascar has been celebrated for its luxuriant vegetation, and in the north and east, where the climate is moist, magnificent forests clothe the hills. Elsewhere vegetation forms a narrow belt along the shore. The Ravenala, or traveller's tree, is characteristic of the island. (Rev. W. Ellis, Rev. Dr. Mullens.)

From this sketch of the principal forest lands of the world it appears that, although the progress of civilization and the increase of population have greatly diminished the area of forests in many countries, they still cover a large portion of the earth's surface, and the necessity of maintaining them is now generally recognized. It is beyond doubt that these vast wooded tracts affect most powerfully the economy of the globe. The direct influences may be summarized from the results arrived at by Humboldt and others:—(1) By screening the soil from the heat of the sun's rays; (2) by the immense surface these leaves offer to the cooling process of radiation; and (3) by the copious evaporation of moisture from the leaves. Some of the indirect benefits which thus accrue from the presence of forests may be mentioned, such as the maintenance of equable temperature and humidity, the affording of protection and shelter, the control of the regular flow of rivers, and the supply of perennial springs which fertilize and beautify the country. It is the climatic and physical importance of a due proportion of wooded land, independent of the utility of forest products in innumerable arts which now contribute to our comfort and progress, that has at length awakened most of the civilized Governments to the necessity of protecting forests from ruthless spoliation. The following general conclusions adopted in 1851 by the British Association committee already referred to contain principles which, although limited in the first instance to British India, have been found more or less applicable to all countries:—

1. That over large portions of the globe there is still an almost uncontrolled destruction of the indigenous forests in progress, from the wasteful habits of the population.

2. That where conservancy has been introduced, considerable improvement has already taken place.

3. That these improvements may be extended by a rigid enforcement of the present regulations, and the enactment of additional provisions of the following character, viz.,—careful maintenance of the forest by valuation surveys and working plans, and by the preservation or plantation of seedlings in place of mature trees removed,—nurseries being established; prohibition of cutting until trees are well grown, with rare and special exceptions for peculiar purposes; and provision, in the case of trees yielding gums, resins, or other valuable products, that greater care be taken in tapping or notching the trees, most serious damage in some countries resulting from neglect in this operation.

4. That especial attention should be given to the preservation and maintenance of the forests occupying tracts unsuited for other culture, whether by reason of altitude or peculiarities of physical structure.

5. That in a country to which the maintenance of its water supplies is of extreme importance, the indiscriminate clearing of forests around the localities whence those supplies are derived is greatly to be deprecated.

6. That it is a duty to prevent the excessive waste of wood, the timbers useful for building and manufactures being reserved and husbanded.

7. That as much local ignorance prevails as to the number and nature of valuable forest products, measures should be taken to supply through the officers in charge information calculated to diminish such ignorance.

Necessity has caused the adoption of these principles in many lands of both the New and the Old World, and forestry will henceforth be studied as a science as well as practised as an art. It is manifestly of the greatest importance that, in the progressive development of great countries, just and enlightened principles should influence the views and actions of those who are charged with the duty of advising Government in regard to the material resources committed to their care for behoof of present and future generations.

For greater detail and more exhaustive treatment of the subject, the reader is referred to the following works in addition to those already alluded to:—GREAT BRITAIN. Forest Law.

One of the most cherished prerogatives of the king of England, at the time when his power was at the highest, was that of converting any portion of the country into a forest in which he might enjoy the pleasures of the chase. The earliest struggles between the king and the people testify to the extent to which this prerogative became a public grievance, and the charter by which its exercise was bounded (Charta de Foresta) was in substance part of the great constitutional code imposed by his barons upon King John. At common law it appears to have been the right of the king to make a forest where he pleased, provided that certain legal formalities were observed. The king having a continual care for the preservation of the realm, and for the peace and quiet of his subjects, he had therefore amongst many privileges this prerogative, viz., to have his place of recreation wheresoever he would appoint.[1] Land once afforested became subject to a peculiar system of laws, which, as well as the formalities required to constitute a valid afforestment, have been carefully ascertained by the Anglo-Norman lawyers. "A forest," says Manwood, "is a certain territory of woody grounds and fruitful pastures, privileged for wild beasts and fowls of forest, chase, and warren to rest, and abide there in the safe protection of the king, for his delight and pleasure; which territory of ground so privileged is mered and bounded with unremovable marks, meres, and boundaries, either known by matter of record or by prescription; and also replenished with wild beasts of venery or chase, and with great coverts of vert, for the succor of the said beasts there to abide: for the preservation and continuance of which said place, together with the vert and venison there are particular officers, laws, and privileges belonging to the same, requisite for that purpose, and proper only to a forest and to no other place."[2] And the same author distinguishes a forest as "the highest franchise of princely pleasure," from the inferior franchises of chase, park, and warren—named in the order of their importance. The forest embraces all these, and it is distinguished by having laws and courts of its own, according to which offenders are justiceable. An offender in a chase is to be punished by the common law; an offender in a forest by the forest law. A chase is much the same as a park, only the latter is enclosed, and all of them are distinguished according to the class of wild beasts to which the privilege extended. Thus, beasts of forest (the "five wild beasts of venery") were the hart, the hind, the hare, the boar, and the wolf. The beasts of chase were also five, viz., the buck, the doe, the fox, the marten, and the roe. The beasts and fowls of warren were the hare, the coney, the pheasant, and the partridge. (See GAME LAWS.)

The courts of the forest were three in number viz., the court of attachments, swanimote, and justice-seat. The court of attachments (called also the wood-mote) is held for the foresters to bring in their attachments concerning any hurt done to vert or venison (*in viridi et venatione*) in the forest, and for the verderers to receive and mark the same, but no conviction takes place. The swanimote is the court to which all the freeholders within the forest owe suit and service, and of which the verderers are the judges. In this court all offences against the forest laws may be tried, but no judgment or punishment follows. This is reserved for the justice-seat, to which the rolls of offences presented at the court of attachment, and tried at the swanimote, are presented by verderers. The justice-seat is the court of the chief justice in eyre, who, says Coke, "is commonly a man of greater dignity than knowledge of the laws of the forests; and, therefore, where justice-seats are to be held, some other persons whom the king shall appoint are associated with him, who together are to determine *omnia placita forestæ*." There were two chief justices for the forests *intra* and *ultra Trentam* respectively. The necessary officers of a forest are a steward, verderers, foresters, regarders, agisters, and woodwards. The verderer was a judicial officer chosen in full county by the freeholders in the same manner as the coroner. His office was to view and receive the attachments of the foresters, and to mark them on his rolls. A forester was "an officer sworn to preserve the vert and venison in the forest, and to attend upon the wild beasts within his bailwick." The regarders were of the nature of visitors: their duty was to make a regard (*visitatio nemorum*) every third year, to inquire of all offences, and of the concealment of such offences by any officer of the forest. The business of the agister was to look after the pasturage of the forest, and to receive the payments for the same by persons entitled to pasture their cattle in the forests. Both the pasturage and the payment were called "agistment."

The legal conception of a forest was thus that of a definite territory within which the code of the forest law prevailed to the exclusion of the common law. The ownership of the soil might be in any one, but the rights of the proprietor were limited by the laws made for the protection of the king's wild beasts. These laws, enforced by fines often arbitrary and excessive, were a great grievance to the unfortunate owners of land within or in the neighborhood of the forest. The offence of "purpresture" may be cited as an example. This was an encroachment on the forest rights, by building a house within the forest, and it made no difference whether the land belonged to the builder or not. In either case it was an offence punishable by fines at discretion. And if a man converted woodlands within the forest into arable land, he was guilty of the offence known as "assarting," whether the covert belonged to himself or not.

[2] Manwood's *Treatise of the Forest Laws*, 4th edition, 1717.

The hardships of the forest laws under the Norman kings, and their extension to private estates by the process of afforestment, were among the grievances which united the barons and people against the king in the reign of John. The Great Charter of King John contains clauses relating to the forest laws, but no separate charter of the forest. The first charter of the forest is that of Henry III., issued in 1217. "As an important piece of legislation," says Professor Stubbs,[1] "it must be compared with the forest assize of 1184, and with 44th, 47th, and 48th clauses of the charter of John. It is observable that most of the abuses which are remedied by it are regarded as having sprung up since the accession of Henry II.; but the most offensive afforestations have been made under Richard and John. These latter are at once disafforested; but those of Henry II. only so far as they had been carried out to the injury of the landowners and outside of the royal demesne." Land which had thus been once forest land and was afterwards disafforested was known as *purlieu*—derived by Manwood from the French *pur* and *lieu*, *i.e.*, "a place exempt from the forest." The forest laws still applied in a modified manner to the purlieu. The benefit of the disafforestment existed only for the owner of the lands; as to all other persons the land was forest still, and the king's wild beasts were to "have free recourse therein and safe return to the forest, without any hurt or destruction other than by the owners of the lands in the purlieu where they shall be found, and that only to hunt and chase them back again towards the forest without any forestalling" (Manwood, *On the Forest Laws*—article "Purlieu").

The revival of the forest laws was one of the means resorted to by Charles I. for raising a revenue independently of parliament, and the royal forests in Essex were so enlarged that they were hyperbolically said to include the whole county. The earl of Southampton was nearly ruined by a decision that stripped him of his estate near the New Forest. The boundaries of Rockingham Forest were increased from six miles to sixty, and enormous fines imposed on the trespassers,—Lord Salisbury being assessed in £20,000, Lord Westmoreland in £19,000, Sir Christopher Hatton in £12,000 (Hallam's *Constitutional History of England*, c. viii.). By the statute 16 Charles I. c. 16 the royal forests were determined for ever according to their boundaries in the twentieth year of James, all subsequent enlargements being annulled. (E. R.)

FORFAR, or ANGUS, a maritime county of Scotland, is situated between 56° 27′ and 56° 59′ N. lat., and between 2° 26′ and 3° 24′ W. long. It is bounded on the N. by the shires of Aberdeen and Kincardine, on the E. by the German Ocean, on the S. by the Firth of Tay, which separates it from Fife, and on the W. by Perthshire. Its greatest length from north to south is about 37 miles, and its greatest breadth from east to west 27 miles; its average length is about 35 miles, and its average breadth about 25 miles. The area comprises 890 square miles or 569,840 imperial acres.

Forfar presents great variety of surface. The northern division, comprising nearly half the county, is occupied by the Binchinnin hills or "Braes of Angus," which form part of the Grampian mountain range, and join the "Braes of Mar" in Aberdeenshire. At the head of Glen Clova they rise boldly and abruptly, and are clothed in summer by a green covering of grass; but for the most part they are rounded and rather tame, and covered with a thin coat of moorish soil bearing stunted heath. The highest summit is Glas Meal, 3502 feet, and a large number are over 3000 feet. The range is intersected by several wooded and fruitful valleys, the principal of which are Glen Isla, Glen Prosen, Glen Clova, Glen Lethnot, and Glen Esk. These are watered by streams that rise in the west and north, and commonly flow south-east, receiving the mountain torrents in their progress. Some miles south from the Grampians, and parallel to them, there is another and lower mountain range called the Sidlaw hills, the higher eminences generally covered with moor and heath, but the lower ridges cultivated or wooded. Their highest summits are Auchterhouse hill (1399 feet), and Gallow hill (1242); and a considerable number are above 1100 feet. The breadth of this range is from 3 to 6 miles. Between these two mountain districts lies Strathmore or the Great Valley, as the name means in Gaelic, or, as it is commonly called, the "Howe of Angus," forming a continuation of the "Howe of the Mearns," and having a breadth of from 6 to 8 miles,—a district beautifully diversified by gentle eminences, fertile fields, plantations, villages, and gentlemen's seats, very little of it being 200 feet above sea-level. From the Sidlaw Hills to the German Ocean on the east and the Firth of Tay on the south there extents a tract of low and level ground, varying in breadth from 3 to 8 miles, and comprehending about a fourth part of the whole county. The southern shore is level and sandy, but from Arbroath to Lunan Bay the coast line is formed of sandstone cliffs, in some parts very steep and precipitous, and containing a number of caves, most of which are only accessible from the sea.

The principal rivers are the Isla, the South Esk, and the North Esk. The Isla rises in the Grampians in the north-west of the county, and flows from north to south through the glen which bears its name, until at Ruthven it bends to the westward and joins the Tay in Perthshire. Below the Bridge of Craigs it has cut a chasm, in some places more than 100 feet in depth, through a barrier of porphyry and gravel stone rocks, where it forms cascades of singular beauty. The South Esk has its source in the Grampians a few miles east of the Isla, and flows south-east till it reaches the valley of Strathmore, after which it takes an eastward course, and passing Brechin discharges itself into the basin of Montrose. The North Esk issues from Loch Lee, and, flowing first eastward and then south-east, forms for about 10 miles of its course the boundary between this county and that of Kincardine, and falls into the sea about 3 miles north-east of Montrose. Among the smaller streams are the Dean, a tributary of the Isla; the Prosen, which falls into the South Esk; the Mark, the Westwater, and the Cruick, which join the North Esk; the Dighty, which flows south-eastwards into the Firth of Tay at Broughty Ferry; and the Lunan, which empties itself into the German Ocean at Lunan Bay. There are a number of small lochs, the principal being Loch Lee, Lintrathen Loch, and the lochs of Forfar, of Rescobie, and of Balgavies.

Geology and Minerals.—In the northern portion of the Forfarshire Grampians the prevailing rock is granite, some of it very beautiful, and containing in its cavities topazes and rock crystals called "cairngorms," from the mountain of that name in Aberdeenshire. Other portions of the Grampians are composed of micaceous schist and porphyry, dykes of the latter in some places intersecting the former. Laminated mica is found in veins in mica slate, and rock crystals are found in the beds of torrents. Lead was at one time wrought at Gilfianan, above the old castle of Invermark, in the upper part of the parish of Lochlee; and according to Edward, in his *Description of Angus* published in 1678, it yielded one sixty-fourth part of silver. It has also been wrought at Ardoch near Milden on the Esk. Limestone occurs in various parts of the Grampians, and jasper is frequently embedded in the micaceous schist. In the lower portions of the Grampians pudding-stone prevails, and afterwards sandstone. Clay marl is found both in Strathmore and the Sidlaw hills. Shell marl abounds in the beds of the various lochs, some of which have been partly or wholly drained to render it easy of access. The Sidlaw hills are chiefly composed of sandstone of various colors. Sandstone flags are quarried in large quantities on the hill of Balmashanner, in the moor to the south of Forfar, in the parish of Carmylie, and along the southern declivity of the Sidlaw hills. In this sandstone district lies the famous *Forfarshire fishbed*, containing the earliest known vestiges of vertebrate life.[2] In the maritime district there are numerous beds of red sandstone, which, however, are frequently intersected by whinstone and porphyry. The principal limeworks are in this division,—at Hedderwick near Montrose, and at Boddin in the parish of Craig.

Climate and Agriculture.—The climate differs considerably in various parts of the county; but is on the whole salubrious and favorable for agricultural pursuits. According to observations taken by Alexander Brown, LL.D., at Arbroath, for ten years, from March, 1868, to March, 1878, the mean of the barometer, reduced to sea-level and a temperature of 32° F., was 29·83 inches. The mean temperature was in spring 46°·1 F., summer 58°·3, autumn 47°·7, winter 39°·0. The mean annual rainfall was 29·8 inches. The average annual number of days whereon the wind was from the N. was 29, N.E. 15, E. 26, S.E. 28, S. 69, S.W. 36, W. 78, and N.W. 38, while 46 were calm. In

Strathmore, owing to the proximity of the Grampians, the rainfall is considerably greater than in the maritime district. In these two districts the harvests are nearly as early as in any other district of Scotland, but in many of the uplands they are often very late. The total area of arable ground in 1878 was 252,902 imperial acres, of which 95,448 were under corn crops, 51,396 under green crops, 81,415 under rotation grasses, 24,295 permanent pasture, and 348 fallow. There were 31,857 acres under wood. The principal wheat district is the valley of Strathmore and the neighborhood of Dundee and Montrose; and the yield is excelled by few districts in Scotland. Its acreage (9416 in 1878) has, however, as elsewhere in Scotland, been decreasing, while there has been a gradual increase in that of barley (31,593 acres in 1878). Oats, for which the soil generally is well adapted, are the principal crop, the acreage (1878) being 52,802. Potatoes are chiefly grown in the upland and maritime districts; the acreage was 16,479. As a large number of sheep and cattle are kept, turnips are very largely grown, their acreage being 33,953. The acreage under beans was only 1060. The system of rotation varies according to soil and situation. The five years' shift, at one time the most common, has of late been largely superseded by a seven-shift. The number of cattle in 1878 was 44,405, or an average of nearly 17·8 to every 100 acres under cultivation as compared with 23·6 for Scotland. Of these the number of cows and heifers in milk or in calf was only 11,452, and except in the vicinity of the towns there are no dairy farms. The polled Angus cattle are not so much bred in this their native district as in the neighboring county of Aberdeen. Shorthorns are now being largely introduced. A large number of Irish cattle are imported for winter feeding. Forfar has suffered more from contagious diseases than any other Scotch county. Their prevalence is thought by some to be partly due to the practice of letting grass and turnips to be consumed by the cattle of dealers and middlemen. The number of horses was 10,164 or an average of nearly 4 to every 100 acres under cultivation, just the average for Scotland. The most common breed is the Clydesdale, the small native *garrons* being now little used. The number of sheep was 122,798, an average of 50·1 to every 100 acres under cultivation, as compared with 149·3 for Scotland. The black-faced breed are the most common in the mountain districts, but their number has been much diminished of late years, owing to the large extent of country that has been converted into deer forests. Cross-bred lambs are bought in considerable numbers for winter-feeding in the lowland districts, and cross-bred ewes are kept on many farms for breeding. There are also a few flocks of pure-bred Border Leicesters, and some Shropshire downs and other varieties. The number of pigs was 5900, or an average of 2·3 to every 100 acres, as compared with 3·3 for Scotland.

In Forfar the holdings called crofts, of 10 acres and under, and those from 100 to 300 acres are the most common. A large number are between 10 and 100 acres, a considerable number between 300 and 500, and a few above 500. The general color of the soils in the lower districts is red, in other parts often inclining to dark-brown or black. The soil in the Grampians is generally moorish over white retentive clay, but loose, friable, and productive in the glens. Over the pudding-stone, in the lower grounds, it is sometimes thin, mossy, and encumbered with stones, and over the sandstone a tenacious clay often occurs, which, however, when properly cultivated, is very productive. The soil above whinstone is fertile though sometimes shallow. Along the coast there are large stretches of barren sand, but the soil of the district where cultivated is quick and very fertile. There is no great extent of peat; but nearly the whole of the northern division of the county is either waste land or occupied as sheep walks or deer forests. Farm management, except in the case of the crofts, is fully abreast of the times. Steam-cultivation is gradually increasing, and reaping machines are universally in use. Most farms possess excellent farm-houses and steadings, and covered courts for cattle are generally in use. Considerable progress has been made in the erection of suitable cottages for the farm servants, but bothies for unmarried servants are much too common in the county, and in these the accommodation provided is often of the rudest kind.

According to the owners and heritages return of 1872–73, the land, exclusive of Dundee, was divided between 4898 proprietors, holding land the gross annual value of which was £795,581, 7s. Of the owners 80 per cent. possessed less than one acre, and the average value all over was £1, 8s. 8¾ d. There were no fewer than 20 proprietors holding upwards of 5000 acres, viz., Earl of Dalhousie (Brechin Castle), 136,602; Earl of Airlie (Cortachy Castle), 65,059; Earl of Southesk (Kinnaird Castle), 22,525; Donald Ogilvie of Clova (Balnaboth), 21,893; Glamis Trustees (Glamis), 17,034; James Small (Brewlands), 10,300; Fotheringham Trustees (Fotheringham House), 8826; Helen C. Arbuthnott (Balnamoon), 8066; James T. Mackenzie, 7129; Hon. Mrs. E. Maule of Fearn, 6992; Lord Wharncliffe (Belmont Castle), 6926; Major W. Lyon, 6888; Earl of Camperdown (Camperdown House), 6770; Col. Ogilvy of Ruthven, 6336; Trustees of Charles Lyell, 5728; Sir Thomas Munro, Bart. (Lindertis), 5702; J. L. D. Stewart (Glenogil), 5524; Countess of Home, 5209; Lord John F. G. Hallyburton (Hallyburton House), 5199; Trustees of Robert Smith (Baharry), 5097.

There are extensive grouse and blackcock shootings on the moors; the roe deer is met with on the mountains, and the stag is also occasionally seen; the alpine hare is plentiful on the uplands; eagles tenant the cliffs of the Grampians; there are numerous waterfowl in the lochs; and otters and seals inhabit the eastern coast. Particulars regarding the botany of the county will be found in William Gardner's *Botany of Forfarshire.*

Manufactures and Trade.—The staple industry of Forfarshire is the manufacture of flax and jute, Dundee being the principal seat of the linen trade in Britain. Besides employing a large portion of the population of the burghs, linen in various forms is also manufactured at Kirriemuir, Coupar Angus, Carnoustie, Friockheim, Edzell, Lochee, Letham, Monifieth, and Newtyle. In some villages hand-loom weaving exists to a considerable extent. According to the census returns for 1871, the number of persons engaged in the different branches of the linen manufacture was 45,633, 15,418 males and 30,215 females. There are breweries, tanneries, and bleach-works in most of the towns. The herring, white fish, and salmon fisheries are pretty extensive. The number of herring boats connected with the Montrose district is upwards of 900, with a total estimated value of nearly £50,000.

The number of royal burghs, all of which are also parliamentary, is five, viz., Dundee, Arbroath, Brechin, Forfar, and Montrose. The other towns and the principal villages on the coast are—Broughty Ferry (5817), a watering place and suburb of Dundee; the manufacturing village of Monifieth (919); Carnoustie (3012), a watering place, but possessing also manufactures and fisheries; and the fishing villages of Auchmithie (412) and Ferryden (1395). Inland there are Coupar Angus (the larger part of which is, however, in Perthshire), Kirriemuir (4145), Friockheim (1129), Letham (953), Newtyle (542), and Edzell (415), all chiefly engaged in the linen manufacture. The total population of the county in 1871 was 237,567, of whom 106,324 were males and 131,243 females; the population in 1861 was 204,425. In the towns the population in 1871 was 186,185, in the villages 8203, and in the rural districts 43,179, as compared with 149,309, 6602, and 48,514 respectively in 1861.

One member of parliament is returned by the county, two by the burgh of Dundee, and the other burghs unite with Inverbervie in Kincardineshire in returning a third.

History and Antiquities.—Forfar belongs to that portion of Scotland inhabited in the time of the Romans by the Picts. The county is supposed by some to have received the name Angus from being granted to a son of one of the Scottish kings who bore that name; but others trace the origin of the title to a Gaelic designation for a particular kind of hill, and connect its use with the hill of Angus, to the east of the church of Aberlemno. It is only a few centuries ago that the name Forfar, borrowed from the county town, was applied to the whole county. In ancient times the county was governed by hereditary earls, and it was made an hereditary sheriffdom by David II. The principal historical events, not connected immediately with the burghs are the supposed Roman battle of the Grampians; the battle of Egfrid, king of Northumbria, and Bridei, king of the Picts, near Dunnichen, in 685, in which the former was slain; battles with the Danes at Aberlemno and other places; the defeat of Elpin, king of the Scots, by Ængus, in the parish of Liff, in 730; a battle between the Picts and Scots near Restinoth, about the year 835; and the defeat of Lord Montfort near Panmure by the earls of Fife and March about the year 1336.

In various parts of the county pretty entire remains of the "weems," or old subterranean dwellings of the Celts, are found; traces of Roman camps are very common; there are a large number of stone forts, and there are vitrified forts at Finhaven, at Dumsturdy Muir, and on the hill of Laws, near Monifieth. Spear heads, battle-axes, sepulchral deposits, Scandinavian bronze pins, gold bullets (used for coin), and other antiquarian remains are frequently met with. There are sculptured stone pillars at Aberlemno, Auldbar, Glammis, Kirriemuir, St. Vigeans, and other places. The principal ecclesiastical antiquities are connected with the burghs. Among the old castles may be mentioned the roofless square tower of Redcastle, at the mouth of the Lunan; the old tower of the modern castle of Guthrie; the tower of the castle of Auchinleck; the stronghold of Inverarity, near Kirriemuir; the large square keep of Broughty castle; the ruins of the castle of Finhaven; the two towers of the old Edzell castle; the ruins of Melgund castle, which are in a pretty entire condition; the ancient part of the splendid castle of Glammis; the small castle of Newtyle; the old square tower and gateway of the castle of Craig; and the remains of the old castle of Airlie, whose burning by the earl of Argyll in 1640 gave rise to the ballad of "The bonnie house of Airlie." The number of fine modern residences is too great to admit of their being here particularized.

The principal works on Forfarshire are Edward's *Description of Angus*, published in 1678, and reprinted in 1791; *Forfarshire Illustrated*, 1843; Gardner's *Botany of Forfarshire;* and *Memorials of Angus and the Mearns*, by Andrew Jervise, 1861.

FORFAR, a royal and parliamentary burgh of Scotland, and capital of the county of the same name, is situated in the valley of Strathmore near the railway from Aberdeen to Perth. The principal buildings are the court-house, the town-hall, the county buildings and the infirmary. The staple industry is the linen manufacture, but there are also breweries and tanneries. Forfar is of considerable antiquity, having been constituted a burgh before 1300. It was at one time the residence of royalty; and in the accounts of the chamberlain of the royal household, in the reign of Alexander III., and of some preceding monarchs, a charge is entered for the king's gardeners at Forfar. The town was protected by a castle which stood on a mound on the north side. Its origin is uncertain, but it is believed to have been the place where, in 1057, the first parliament of Malcolm Canmore assembled after the defeat of Macbeth. It was occupied and strongly garrisoned by the English in the beginning of the 14th century; but in 1307 Bruce, on his way through Angus, captured and destroyed it, putting the English to the sword. Its site is now marked by the town cross. It appears that the weekly market-day previous to the reign of James VI. was Sunday, when it was changed by Act of Parliament to Friday. In 1661 a special commission was appointed by the crown to try several parties accused of witchcraft, some of whom were condemned to be burnt. The bridle which was put into their mouths in leading them out for execution is still preserved in the burgh. Further, it is recorded that John Ford, for his services as a "witch ricker," was on the same occasion admitted a burgess along with Lord Kinghorn. Previous to the middle of last century, the town possessed very few houses of two stories; and notwithstanding its proximity to good gray slate quarries, the houses were almost all thatched. This burgh unites with Montrose, Arbroath, Brechin, and Inverbervie in sending one member to parliament. The population of the burgh (royal and parliamentary) in 1861 was 9258, and in 1871, 11,031.

FORGE, a fire urged by a blast for the purposes of the smith. Of late years many improvements have been made in its construction. Formerly the forge was almost made entirely of bricks, and many so constructed exist still. From the attention of engineers having been called to the special requirements and increasing wants of the day, the old forge has undergone many changes. Undoubtedly these changes are for the better. The modern forge leaves little to be desired. It is only in cases where the metal is of small dimensions, and the work of rare occurrence, that the old method of building them in brick is still resorted to. The forge seen in country smithies and in small shops is made entirely of bricks. It is generally built against a wall upon arches to a convenient height. The hearth, which should be made with fire-bricks, is sunk to a depth of three inches or more, according to the nature of the work for which it is constructed; so that the upper and outer course of brickwork forms a rim. About 2 feet 6 inches, more or less, above the hearth is placed the hood. This is also made of brick, and is built upon a flat iron rim. It is cone shape, and at the apex is an orifice leading into a flue for the escape of the smoke. In front of the forge is placed a water tank for quenching the work, tools, etc. The tuyere or tweer is placed at the back of the hearth, as well as a small watertank for keeping the nozzle from burning under the action of the severe heat to which it is submitted. A pair of bellows, either single or double, worked by a rocking staff or lever is placed on one side of the forge in a convenient position. The bellows are placed on each side, if the forge be provided with two fires; when this is the case it is called a double forge. Modern or the latest constructed forges are made almost entirely of cast or wrought iron. The wrought iron forges are as a rule portable for the purpose of ships, dockyards, etc. They are constructed with sheet iron of a suitable gauge, the pieces being riveted together, and generally have the bellows placed underneath the hearth so that it may be out of the way. This particularly applies to portable forges of any description. Cast iron forges (either single or double) are cast in one or two pieces, and are of superior thickness, so as to give strength and solidity. They are used as fixed hearths in shops. They are bricked up when the work is of a very heavy nature so as to support the weight. The hoods of these forges are also made of cast iron, and are bolted on to the main casting. They vary in shapes and sizes. Messrs. Handyside of Derby have designed some which have found much favor in the English Government and other works. Some of the smaller forges are now fitted with a fan blast—to be worked by hand. These are very powerful, and give a very uniform current of air. They also have the advantage of being made entirely of metal, which adds considerably to their strength and lightness. The exertion in blowing is much less with them than with the ordinary bellows, from the motion being circular and the fan running between centres. At the Paris Exhibition (1878) there were several forges constructed upon an improved method. The blast was obtained by a pump, a reservoir being attached for maintaining the current—which was very easy to keep up.

In large smithies the hearths are all placed in a row or scattered about the shops in convenient situations, each having a flue passing through the roof. They are worked by a powerful air blast situated at one end of the building. The air is conveyed by a series of main pipes sunk to the depth of a few feet under the ground. Smaller tubes are employed to convey the blast to the hearths. Under these circumstances the smith has but to turn a small lever, in order to open or close the air-valve which is placed in a small standard at the side of each hearth. By this means the workman is saved much labor and consequenty much time. Steam has also been adopted as a means of forcing air into the forge. With special apparatus for drying the steam it is very successful. It is, however, more adapted to large blast furnaces than those of the smithy. Another description of the forge is the battery forge. This is used in military service. It is constructed somewhat like a caisson. The bellows are situated in the place usually occupied by the ammunition chests. A box to contain coal, a set of tools, horse shoes, iron, and steel is attached to the body of the carriage, which is mounted on a pair of wheels.

The forge gives its name to "Forging," one of the most important arts connected with engineering work. The strength and durability of engines and other machinery in general depends to a very great extent upon the art and care bestowed upon those parts which have to sustain great weight, much strain, and an amount of wear and tear. Thus the smith holds in engineering shops a very important place. He has to depend upon his eye and judgment in many cases where the fitter and turner is assisted by drawings setting forth every detail. The smith, however, of the present day is not such an adept as his predecessor. The introduction of the steam hammer, stamps, etc., have to a great extent rendered his work nothing more than mechanical. To meet the urgent requirements of the present day, he has to study the engine and machine; that he has succeeded is evident, and the manufacturer can produce more work in less time than he could formerly. But though this is undoubtedly a gain, it has unfortunately been the means of rendering skilled manual labor in many branches of our industries almost superfluous. This being the case, the skill on which the older workmen so much prided themselves is slowly disappearing, and indeed has become almost extinct.

One great change in the history of forging was the introduction of the steam hammer in 1833 by Mr. Nasmyth. By the means of that machine, the welding and forging of pieces of metal of any size have become comparatively easy. Mr. Nasmyth's steam hammer has been improved upon by himself from that time, and is now to be seen in almost all engineering shops throughout the world. The tilt hammer is still in use, and for various purposes may be said to be of great utility. But the smaller sizes of steam hammer are more convenient and manageable, and as a natural consequence are rapidly taking its place. To the steam hammer we are indebted for the Y anvil, which is used in the forging of rods and bar iron. Rolling mills are, however, much quicker, and are used in preference.

A forging machine, invented by Mr. Ryder many years back, and still in full operation, possesses many qualities unattainable by any other known means. It consists of a series of small anvils of various sizes. These are held by set screws passing through the frame of the machine, which allow of the anvils being raised or lowered, so that a perfect adjustment might be obtained. The hammers are placed over the anvils, and work up and down in bearings, moved by an eccentric. This is worked by a cradle upon the head; the hammer is raised by a strong spiral spring. The strokes made by this machine vary from 600 to 1200 per minute. According to Mr. Platt (of Platt Brothers, Oldham), one of the original makers of the machine, it is rather a squeeze than a blow which does the work. Many improvements have been added to it by Mr. Platt's firm; and the Bolton blacksmith, as it is commonly called, is now being extensively used in the Government workshops for the manufacture of bayonets, etc. The tools used are wedge-shaped, and the surface of the iron after forging, or rather squeezing, is said to be anything but hard or difficult to file up. The spindles of mules (cotton-spinning machines) are now forged by this tool, and indeed every description of small work. The contour produced by it is such that the work is almost as true as though it had been surfaced in the lathe. There have been several other machines upon Ryder's principle brought out, but none appear to answer so well as that designed by the original inventor.

Another invention, the steam stamp, is now most extensively used. This is similar to a steam hammer; in place of the anvil and hammer head is placed a pair of dies, in which is cut the form of work necessary. The iron is placed over the die, the stroke is delivered, and the iron is forced into the shape of the die. Machinery and separate tools are now often forged in this hammer.

The quality of the coals used in forging is of the utmost importance; the coal preferred by smiths is that which makes plenty of coke, and which leaves after being burnt a quantity of white ashes.

The art of forging is by no means easy to acquire. Great practice is necessary to arrive at excellence in this important branch of our great industries.

See *The Forge* (published by the Society for the Propagation of Christian Knowledge), W. Harrison's *Light of the Forge*, and *The Smith's and Metal Worker's Director*. (D. A. A.)

FORGERY, in English law, is defined as "the fraudulent making or alteration of a writing to the prejudice of another man's right," or "as the false making, or making *malo animo*, of any written instrument for the purpose of fraud or deceit." This definition, it will be seen, comprehends all fraudulent tampering with documents. "Not only the fabrication and false making of the whole of a written instrument, but a fraudulent insertion, alteration, or erasure, even of a letter, in any material part of a true instrument whereby a new operation is given to it, will amount to forgery,—and this though it be afterwards executed by another person ignorant of the deceit" (Russell on *Crimes and Misdemeanors*, vol. ii. p. 619). Changing the word Dale into Sale in a lease, so that it appears to be a lease of the manor of Sale instead of the manor of Dale, is a forgery. And when a country banker's note was made payable at the house of a banker in London who failed, it was held to be forgery to alter the name of such London banker to that of another London banker with whom the country banker had subsequently made his notes payable. As to the fraud, "an intent to defraud is presumed to exist if it appears that at the time when the false document was made there was in existence a specific person, ascertained, or unascertained, capable of being defrauded thereby; and this presumption is not rebutted by proof that the offender took or intended to take measures to prevent such person from being defrauded in fact, nor by the fact that he had or thought he had a right to the thing to be obtained by the false document" (Stephen's *Digest of the Criminal Law*, c. 43). Thus when a man makes a false acceptance to a bill of exchange, and circulates it, intending to take it up and actually taking it up before it is presented for payment, he is guilty of forgery. Even if it be proved as a matter of fact that no person could be defrauded (as when A forges a cheque in B's name on a bank from which B had withdrawn his account), the intent to defraud will be presumed. But it would appear that if A knew that B had withdrawn his account, the absence of fraudulent intention would be inferred. A general intention to cheat the public is not the kind of fraud necessary to constitute forgery. Thus if a quack forges a diploma of the college of surgeons, in order to make people believe that he is a member of that body, he is not guilty of forgery. The crime of forgery in English law has been from time to time dealt with in an enormous number of statutes. "Mr. Hammond, in the title Forgery of his *Criminal Code*, has enumerated more than 400 statutes which contain provisions against the offence" (Sir J. T. Coleridge's notes to Blackstone). Blackstone notices the increasing severity of the legislature against forgery, and says that "through the number of these general and special provisions there is now hardly a case possible to be conceived wherein forgery that tends to defraud, whether in the name of a real or fictitious person, is not made a capital crime." These Acts were consolidated by 1 Will. IV. c. 66, now repealed. The later statutes, fixing penalties from penal servitude for life downwards, were consolidated by the 24 and 25 Vict. c. 98 (the Forgery Act). It would take too much space to enumerate all the varieties of the offence with their appropriate punishments. The following condensed summary is based upon chapter xxiv. of Sir J. Stephen's *Digest of the Criminal Law*.

1. Forgeries punishable with penal servitude for life as a maximum are—

(*a*) Forgeries of the Great Seal, Privy Seal, etc.

(*b*) Forgeries of transfers of stock, India bonds, exchequer bills, bank-notes, deeds, wills, bills of exchange, etc.

(*c*) Obliterations or alterations of crossing on a cheque.

(*d*) Forgeries of registers of birth, etc., or of copies thereof and others.

2. Forgeries punishable with fourteen years' penal servitude are—

(*a*) Forgeries of debentures.

(*b*) Forgeries of documents relating to the registering of deeds, etc.

(*c*) Forgeries of instruments purporting to be made by the accountant general and other officers of the Court of Chancery, etc.

(*d*) Drawing bill of exchange, etc., on account of another, per procuration or otherwise, without authority.

(*e*) Obtaining property by means of a forged instrument, knowing it to be forged, or by probate obtained on a forged will, false oath, etc.

3. Forgeries punishable with seven years' penal servitude:—Forgeries of seals of courts, of the process of courts, of certificates, and of documents to be used in evidence, etc.

Forgery of trade marks is a misdemeanor punishable with two years' imprisonment. (E. R.)

FORGET-ME-NOT, or SCORPION GRASS (German *Vergissmeinnicht;* French, *grémillet, scorpionne*), the name popularly applied to the small annual or perennial herbs forming the genus *Myosotis* of the natural order *Boraginaceæ*, so called from *μύς*, a mouse, and *οὖς*, an ear, on account of the shape of the leaves. The genus is represented in Europe, North Asia, North America, and Australia, and is characterized by oblong or linear stem-leaves; flowers in terminal scorpioid cymes (see BOTANY, vol. iv. p. 113, fig. 169); small ebracteate blue, pink, or white flowers; a five-cleft persistent calyx; a salver or funnel-shaped corolla, having its mouth closed by five short scales; and hard, smooth, and shining nutlets. The common or true Forget-me-not, the Water Myosote, *M. palustris*, With., is a perennial plant growing to a height of 6 to 18 inches, with rootstock creeping; stem clothed with lax spreading hairs; leaves light green, and somewhat shining; buds pink, becoming blue as they expand; corolla rotate, broad, with retuse lobes, and bright blue with a yellow centre. The divisions of the calyx extend only about one-third the length of the corolla, whereas in the other British species of *Myosotis* it is deeply cleft. The forget-me-not, a favorite with poets, and the symbol of constancy, is a frequent ornament of brooks, rivers, and ditches, and, according to an old German tradition, received its name from the last words of a knight who was drowned in the attempt to procure the flower for his lady. It attains its greatest perfection under cultivation, and, as it flowers throughout the summer, is used with good effect for garden borders. A variety, *M. strigulosa*, is more hairy and erect, and its flowers are smaller. The species *M. versicolor* bears both blue and yellow flowers.

FORKEL, Johann Nikolaus (1749–1818), was a native of Coburg in Saxony. As a practical musician, especially as a pianoforte player, Forkel achieved some eminence in his profession; but his claims to a more abiding name rest chiefly upon his literary skill and deep research as a writer and historian in the department of musical science and literature. He obtained the degree of doctor in philosophy, and for some time held the appointment of director of the music at the university of Göttingen. The following is a list of his principal works:—*Ueber die Theorie der Musik*, Göttingen, 1774; *Musicalis Kritische Bibliothek*, Gotha, 1778; *Allgemeine Geschichte der Musik*, Leipsic, 1781. The last is his most important work. He also wrote a *Dictionary of Musical Literature*, which is full of valuable material.

FORLÌ, the ancient *Forum Livii*, a city of Italy, at the head of a province which was formerly a legation of the Papal States. It is situated in a fertile plain between the Montone and the Ronco, a little to the right of the railway line between Rimini and Bologna, about 50 miles S.E. of the latter city. It is a well-built and flourishing town, with broad streets and a central piazza, which was reckoned one of the finest in Italy, but has been completely modernized in 1873. The cathedral is of special interest for the chapel of the Madonna del Fuoco, so called from the long-labored masterpiece of Carlo Cignani; and the church of S. Girolamo contains frescoes said to be by Melozzo da Forlì, the Conception by Guido Reni, and a beautiful tomb erected for a Barbara Ordelaffi of the 15th century. From most of the other churches the paintings have been removed to the *pinacoteca* or picture-gallery in the convent of the Frati della Missione, where, besides Melozzo and Cignani, Palmezzano, Guercino, Guido Reni, and Zanganelli are represented. The citadel, known as Rocca di Ravaldino, was founded in 1361 by Cardinal Albornoz; it is in great measure destroyed, and what still remains is utilized as a prison. Besides its administrative and ecclesiastical offices, the town possesses a chamber of commerce and arts, a public library, and several institutions for higher education. A considerable trade is carried on in the varied agricultural produce of the neighborhood, and there are manufactures of silk ribbons, and twist, of oil-cloth, nitre, wax, matches, and tiles. The population in 1872 was 15,324.

Forlì is said to have been founded either by Livius Salinator or by Lucius Arminius, after the defeat of Hasdrubal on the Metaurus in 207 B. C., but its name does not appear in Strabo or Ptolemy. After the fall of the Roman empire it became a republic, and had authority, it is said, over no fewer than 5 cities and 40 towns and villages. It stood a long siege from the French in 1287, and remained independent till 1315. During the troublous times of the 14th and 15th centuries the Ordelaffi, the Orgogliosi, and other powerful families were in possession of the lordship, which finally came to Pope Julius II. in 1503. In 1521 a battle was fought in the neighborhood by the French and the Spaniards. On the occupation of the country by the republicans in 1797 the town was made the head of the department of the Rubicon. A considerable number of eminent men are natives of Forlì:—Cornelius Gallus, the Latin poet; Guido Bonate, the astrologer; Melozzo, the painter (see next article); and Morgagni, the founder of pathological anatomy, born in 1682. Cignani and Torricelli are both buried in the cathedral.

FORLÌ, Melozzo da (c. 1438–1494), an eminent painter, particularly renowned as the first who practised foreshortening with much success. He was born, as his ordinary designation indicates, at Forlì about the year 1438; he came of a wealthy family named Ambrosi. In all probability, Melozzo studied painting under Piero della Francesca, of Borgo S. Sepolcro; he seems also to have been well acquainted with Giovanni Santi, the father of Raphael. It has been said that he became a journeyman and color-grinder to some of the best masters, in order to prosecute his studies; this lacks confirmation. Only three works are now extant which can safely be assigned to Melozzo. (1) He painted in 1472 the vault of the chief chapel in the church of the Apostoli in Rome, his subject being the Ascension of Christ; the figure of Christ is so boldly and effectively foreshortened that it seemed to "burst through the vaulting;" this fresco was taken down in 1711, and the figure of Christ is now in the Quirinal Palace, not worthy of special admiration save in its perspective quality; while some of the other portions, almost Raphaelesque in merit, are in the sacristy of St. Peter's. (2) Between 1475 and 1480 he executed a fresco, now transferred to canvas, and placed in the Vatican picture-gallery, representing the appointment of Platina by Pope Sixtus IV. as librarian of the restored Vatican library,—an excellent work of dignified portraiture. (3) In the Collegio at Forlì is a fresco by Melozzo, termed the "Pestapepe," or Pepper-grinder, originally painted as a grocer's sign; it is an energetic specimen of rather coarse realism, now so damaged that one can hardly assess its merits. Melozzo also painted the cupola of the Capuchin church at Forlì, destroyed in 1651; and it has been said that he executed at Urbino some of the portraits of great men (Plato, Dante, Sixtus IV., etc.) which are now divided between the Barberini Palace and the Campana collection in Paris; this, however, appears to be more than doubtful, and it is even questionable whether Melozzo was ever at Urbino. In Rome he was one of the original members of the academy of St. Luke, founded by Sixtus IV. He returned to Forlì, probably towards 1480, and died in November, 1494. He contributed sensibly to the progress of pictorial art; and, without being remarkable as a colorist gave well-graded lights, with general care and finish, and fine dignified figures. His works bear a certain degree of resemblance to those of his contemporary Mantegna. Marco Palmezzano was his pupil; and the signature "Marcus de Melotius" on some of Palmezzano's works has, along with the general affinity of style, led to their being ascribed to Melozzo, who has himself been hence incorrectly called "Marco Melozzo."

FORLIMPOPOLI, a town of Italy, about five miles east of Forlì, with a station on the railway between Bologna and Rimini. It was once a bishop's seat, and still possesses a cathedral and an ancient castle. The name and the situation identify it with one of the three places that bore the Latin designation of Forum Popilii. Its history is marked by great vicissitudes. Destroyed by the Lombards and restored by the people of Forlì, it was again laid utterly waste in 1370 by Cardinal Egidio, and though twenty years later it was refounded and refortified by Sinbaldo Ordelaffi, it never recovered its former prosperity. Population in 1872 about 5000.

FORMAN, Simon (1552–1611), a physician and astrologer, was born in 1552 at Quidham, a small village near Wilton, Wiltshire. At the age of fourteen he became apprentice to a druggist at Salisbury, but at the end of four years he exchanged this profession for that of a schoolmaster. Shortly afterwards he entered Magdalen College, Oxford, where he studied chiefly medicine and astrology. After continuing the same studies in Holland he commenced practice as a physician in Philpot Lane, London, but as he possessed no diploma, he on this account underwent more than one term of imprisonment. Ultimately, however, he obtained a diploma from Cambridge university, and established himself as a physician and astrologer at Lambeth, where he was consulted, especially as a physician, by many persons of rank, among others by the notorious countess of Essex. He expired suddenly while crossing the Thames in a boat, September 12, 1611.

A list of Forman's works on astrology is given in Bliss's edition of the *Athenæ Oxonienses;* many of his MS. works are contained in the Bodleian Library, the British Museum, and the Plymouth Library. *A Brief Description of the Forman MSS. in the Public Library, Plymouth,* was published in 1853.

FORMEY, Johann Heinrich Samuel (1711–1797), a German author, was born of French parentage at Berlin, 31st May, 1711. He was educated for the ministry, and at the age of twenty became pastor of the French church at Brandenburg. Having in 1736 accepted the invitation of a congregation in Berlin, he was in the following year chosen professor of rhetoric in the French college of that city, and in 1739 professor of philosophy. On the organization of the academy of Berlin in 1744, he was named a member, and in 1748 became its perpetual secretary. He died at Berlin on the 7th March, 1797. His principal works are *La Belle Wolfienne*, 1741–1753, 6 vols. 8vo, a kind of novel written with the view of enforcing the precepts of the Wolfian philosophy; *Bibliothèque Critique, ou Mémoires pour servir à l'Histoire Littéraire Ancienne et Moderne*, 1746; *Le Philosophe Chrétien*, 1750; *L'Émile Chrétien*, 1764, intended as an answer to the *Émile* of Rousseau; and *Souvenirs d'un Citoyen*, Berlin, 1789. He also published an immense number of contemporary memoirs in the transactions of the Berlin Academy, and besides founding and editing several periodical publications contributed largely to others. He enjoyed a considerable reputation for ability and learning during his lifetime, but his works, which display a varied but somewhat superficial erudition, are now almost forgotten.

FORMIA (formerly *Mola Gaëta* or *Castelmola*), a town of Italy, in the province of Caserta, beautifully situated near the ancient *Via Appia*, on the innermost recess of the Gulf of Gaëta. The surrounding country is occupied with vineyards, olive plantations, and fruit gardens. Formia occupies the site of the ancient Formiæ, said to have been founded by the Tyrrhenians. At an early period it received the Roman franchise and became a municipium. Villas were built near it by many of the noble Romans; and in the grounds of the Villa Caposele there are ruins which are thought by some to have been the baths of the villa of Cicero. The villa Caposele was at one time one of the residences of the kings of Naples. The vine of the Formian hills produced excellent wine in the time of Horace. Population in 1871, 9151.

FORMOSA, in Chinese *Taiwan*, a large island in the Pacific lying between what the Chinese call Nan-hai and Tong-hai, or the Southern and the Eastern Sea, and separated from the Chinese mainland by the strait of Fokien, which has a width of about 91 miles in its narrowest part. It extends from 121° 15′ to 122° 5′ E. long.; Foki, its most northern point, lies in 25° 19′, and its most southern, Lin-hai-shan or South Cape, in 21° 54′ N. lat. Its area is estimated at 14,978 square miles, or about half the size of Ireland. It forms part of the long line of islands which, in the words of Mr. Bridge, are interposed as a protective fortification between the Asiatic coast and the broad expanse of the Pacific, and produces that happy immunity from the typhoon which is enjoyed by the ports of China from Amoy to the Yellow Sea. A chain of mountains, called simply Ta-shan or Great Mountain by the Chinese, traverses the island from N. to S. and attains in several of its summits no inconsiderable elevation. The loftiest point is usually said to be Mu Kang-shan or the "Wooded Mountain," which has been named Mount Morrison by the English, "after the captain of one of the early vessels trading to Taiwanfu," and is said to be 12,850 feet in height; but it is not improbable that this estimate is too high, and that the range really culminates elsewhere. Towards the north the English maps show a Mount Sylvia or Shan-chas-shan, 11,300 feet high, and a summit in the Middle, Western, or Dodds range, 12,800 feet. Be this as it may, Formosa, as far as its vertical relief is concerned, is divided into three regions,—the mountains proper, the broad western versant with its alluvial plains, and the narrow eastern versant terminating in a high and precipitous coast. The formation of the island appears to have been due in part at least to volcanic agency; the Chinese accounts mention a mountain called Ho-shan or Fire Mountain, said to be a small volcano about 20 miles south of Kagee; and European explorers have described the jets of steam and sulphur-springs which occur among the calcareous rocks near Tam-sui. Coal, sulphur, and petroleum are the only mineral productions of Formosa which are known to exist in quantities sufficient to make them of economical importance. The principal coal-fields are in the north of the island, near Kelung and Tam-sui; and the coal is all shipped in Kelung harbor. Till 1877 mining operations were conducted after the simple Chinese fashion; but in that year Mr. Tyzack, an English engineer, engaged by the Chinese Government, opened a pit with a regular shaft 300 feet deep, and all the necessary machinery and engines for the proper working of the mine. The bed of coal is 3 feet thick. The mineral is highly bituminous, and burns very fast, but can be used for steamers on short voyages. It is regularly employed by many foreign vessels, as well as in the Chinese men-of-war, and in the arsenal at Fuh-chow. In 1873, 45,000 tons were shipped in foreign ships; in 1874, 15,221 tons; in 1875, 27,665 tons; and in 1876, 31,593 tons. In the plains the soil is generally of sand or alluvial clay, covered in the valleys with a rich vegetable mould. As might be inferred from what has been already said, the streams that flow eastward are little better than torrents; but the western region is traversed by several rivers of moderate development—the Taiwanfu and Pakan rivers, the Black river, the Lokan, the Taika, the Heon-lang, the Tion-kan, the Tonk-shan, and the Tam-sui. Of these the Black river is the widest, but the Tam-sui or Tang-shui-khi alone is navigable, allowing sea vessels to proceed about 3 miles inland, and junks of considerable size about 10 miles farther. There is a fine lake 4 miles long by 2 broad called the Tsui-sia-hai, or Lake of the Water Savages, not far from Posia. The scenery of Formosa is frequently of majestic beauty; and to this it is indebted for its European name, happily bestowed by the early Spanish navigators. As seen from the eastern coast "the outline of the mountains is at once beautiful and fantastic; domes and peaks and wall-like precipices succeed each other in striking variety; a brilliant verdure clothes their sides, down which dash cascades that shine like silver in the tropical sunlight" (Bridge in *Fortnightly Review*, 1876). The climate, though a tropical one, is agreeable and healthy, being tempered by the influences both of the sea and the mountains. According to thermometric observations made at Kelung in 1874, the hottest months are June, July, August, and September, with an average of from 81·76° to 82·81° F. in the shade, and the coldest month is January, with an average of 57·70°. The thermometer almost reached 90° in the early part of July, and in January was frequently about 52° or 55°. For the same year the rainfall amounted to 118 inches, of which the most fell in January, February, March, and May. The vegetation of the island is characterized by tropical luxuriance,—the mountainous regions being clad with dense forest, in which various species of palms, the camphor-tree (*Laurus Camphora*), and the aloe are conspicuous. Mr. Swinhoe obtained no fewer than 65 different kinds of timber from a large yard in Taiwanfu; and his specimens are now to be seen in the museum at Kew. The tree which supplies the materials for the pith paper of the Chinese is not uncommon, and Mr. Pickering found the cassia tree in the mountains. Travellers are especially struck with the beauty of some of the wild flowers, more especially with the lilies and convolvuluses; and our European greenhouses have been enriched by several Formosan orchids and other ornamental plants. The pine-apple grows in abundance. In the lowlands of the western portion, the Chinese have introduced a large number of cultivated plants and fruit trees. Rice is grown in such quantities as to procure for Formosa the title of the "granary of China;" and the sweet potato, taro, millet, barley, wheat, and maize are also cultivated. Sugar, tea, indigo, ground pea-nuts, jute, hemp, oil, and ratans are all articles of export, and some of them produce no inconsiderable trade. The principal tea district is about Banka, but the area devoted to this valuable crop is rapidly increasing. A large part of the tea finds its way to America. In some parts of the island it is probable that coffee may be grown with advantage. The Formosan fauna has been but partially ascertained; but at least three kinds of deer, wild boars, bears, goats, monkeys (probably *Macacus speciosus*), squirrels, and flying squirrels are fairly common, and panthers and wild cats are not unfrequent. A poisonous but beautiful green snake is often mentioned by travellers. Pheasants, ducks, geese, and snipe are abundant; and Dr. Collingwood in his *Naturalist's Rambles in the China Seas* mentions *Ardea prasinosceles* and other species of herons, several species of flycatchers, kingfishers, shrikes, and larks, the black drongo, the *Cotyle sinensis*, and the *Prinia sonitans*. Dogs are kept even by the savages for hunting. The horse is hardly known, and his place is taken by the ox, which is regularly bridled and saddled and ridden with all dignity. The rivers and neighboring seas seem to be well stocked with fish, and especial mention must be made of the turtles, flying-fish, and brilliant coral-fish which swarm in the waters warmed by the *Kurosiwo* current, that gulf-stream of the Pacific. Shell-fish form an important article of diet to both the Chinese and the aborigines along the coast,—a species of Cyrena, a species of Tapes, *Cytherœa petechiana*, and *Modiola teres* being most abundant.

The inhabitants of Formosa may be divided into three classes:—the Chinese, many of whom have immigrated from the neighborhood of Amoy and speak the dialect of that district, while others are Hakkas from the vicinity of Swatow; the subjugated aborigines, now largely intermingled with the Chinese; and the uncivilized aborigines of the eastern region, who refuse to recognize the Chinese authority, and carry on raids as opportunity occurs. The semi-civilized aborigines, who have adopted the Chinese language, dress, and customs, are called Pe-pa-hwan (*Anglice* Peppo-hoans), while their wilder brethren bear the name of Che-hwan or green savages. They appear to belong to the Malay stock, and their language, according to Gabelentz's investigations in the *Zeitschrift der Morgenländ, Gesellschaft*, 1859, bears out the supposition.[1] They are broken up into almost countless tribes and clans, many of which number only a few hundred individuals, and their language consequently presents a variety of dialects, of which no classification has yet been effected: in the district of Posia alone, says Dr. Dickson, of the Presbyterian mission, there are "eight different mutually unintelligible dialects." Mr. Corner of Amoy describes the people themselves as of "middle height, broad-chested, and muscular, with remarkably large hands and feet, the eyes large, the forehead round, and not narrow or receding in many instances, the nose broad, the mouth large and disfigured with betel." The custom of tattooing is universal. In the north of the island at least, the dead are buried in a sitting posture under the bed on which they have expired. Petty wars are extremely common, not only along the Chinese frontiers, but between the neighboring clans; and the heads of the slain are carefully preserved as trophies. In some districts the young men and boys sleep in the skull-chambers, in order that they may be inspired with courage. Many of the tribes that have had least intercourse with the Chinese show a considerable amount of skill in the arts of civilization. The houses, for instance, of the village of Ka-fri-ang in the south are described by Rev. W. Campbell as "built of stone, tiled with immense slabs of a slaty kind of rock, and fitted up within with accommodation for sleeping comfortably as well as for cooking, and for storing up abundance of materials for personal and household use." Manchester prints and other European goods are in pretty general use; and the women, who make a fine native cloth from hemp, introduce colored threads from the foreign stuffs, so as to produce ornamental devices. The office of chieftain is sometimes held by women. Intermarriage between the Chinese and the natives is very common.

The Chinese portion of the island was till 1876 divided into the districts of Komalan, Tam-sui, Chang-hua, Kia-i, Tai-wan, Feng-shan, of which Komalan or Kapsiulangting was the only one on the eastern side; but the districts of Komalan and Tam-sui have been abolished, and a department of North Formosa established with three dependent magistracies. A highway runs from Bangka in the north to Pangliavu in the south. Beginning at the north we find the following places of importance:—Kelung, the ancient Pe-Kiang, a treaty port in the neighborhood of the mines; Tam-sui, or properly Howei or Hobay, also a treaty port with 100,000 inhabitants, on the harbor of the same name, which is formed by hills upwards of 2000 feet high and has a depth of 3½ fathoms and a bar of 7½ feet; Twa-tu-tia, about 13 miles up the Tam-sui river in a tea district, and possessing a population of 20,000; Mengka, Bangka, or Banca, a little higher up the river, one of the most flourishing commercial towns in the north, with 30,000 inhabitants; Teukcham or Teuxham, a walled town at the head of the Tam-sui district, with a population of 40,000 inhabitants; Heong-san and Tiong-Kang, both near the coast; Oulan and Suikang, both inland; Changhwa the capital of a district, and the second city in the island, with a population of 60,000 or 80,000; Chip-Chip, a large town inhabited solely by Chinese; Kagee, or Chin-la-san, and Ung-Kanbay; Kok-si-Kong, with a small harbor; Taiwanfu, the capital of the island, with 30,000 inhabitants (or according to another statement, 100,000), a treaty port, and the remains of the Dutch port of Zelandia; Takao or Takow, also a treaty port, in 22° 37′ N. lat., 120° 16′ E. long., to the south of Ape's Hill; Pataou or Pitau, a few miles inland, the Feng-shan-hsien of ancient documents; and Tang-Kang, a town of 20,000 inhabitants. Besides these there are many places of several thousands of a population, and the whole of the Chinese territory is dotted with villages and hamlets. The whole island is estimated to contain from one and a half to two million souls, the smaller number being probably nearer the truth. The Chinese influence is rapidly spreading, and the island is more and more attracting the attention of foreigners.

The island of Formosa must have been known from a very early date to the Chinese who were established in the Pescadores. The inhabitants are mentioned in the official works of the Yuan dynasty as Tung-fan or southern barbarians; and under the Ming dynasty the island begins to appear as Kilung. In the beginning of the 16th century it began to be known to the Portuguese and Spanish navigators, and the latter at least made some attempts at establishing settlements or missions. The Dutch were the first, however, to take footing in the island; in 1624 they built a fort, Zelandia, on the east coast, where has since risen the town of Taiwan, and the settlement was maintained for thirty-seven years. On the expulsion of the Ming dynasty in China a number of their defeated adherents came over to Formosa, and, under a leader called in European accounts Coxinga, succeeded in expelling the Dutch and taking possession of a good part of the island. In 1682 the Chinese of Formosa recognized the emperor Kanghi, and since then it has formed part of the empire. In 1714 the Jesuit mathematicians from the court visited the island. In 1782 occurred a most destructive storm, which laid the public buildings in ruins and wrecked twenty-seven of the imperial warships; and in 1788 there broke out a violent rebellion, which was put down only after the loss, it is said, of 100,000 (?) men by disease and sword, and the expenditure of 2,000,000 taels of silver. In the early part of the present century the island was principally known to Europeans on account of the wrecks which took place on its coasts, and the dangers that the crews had to run from the cannibal propensities of the aborigines, and the almost equally cruel tendencies of the Chinese. Among the most notable cases was the loss in 1842 of the British brig "Ann," with fifty-seven persons on board, of whom forty-three were executed at Taiwan. By the treaty of Tientsin (1860) Taiwan was opened to European commerce, but Mr. Swinhoe found the place quite unsuitable for a port of trade, and the harbor of Tam-sui was selected instead. Shortly afterwards a rebellion broke out, to which several of the Chinese authorities fell victims; and for some time the condition of the foreign settlers was rather precarious, while the trade of the new port was so small that it was proposed to relinquish the consulate. In 1865 Dr. Maxwell of the English Presbyterian Church established a medical mission first at Taiwan and afterwards at Takao; and the organization thus originated comprised in 1877 thirteen churches among the Chinese, and as many among the aborigines of the southern provinces, with upwards of 1000 baptized converts and 3000 attendants at worship. The northern provinces are in the hands of the Presbyterian Church of Canada, which commenced its operations in 1872, and had nine stations in 1877. A Roman Catholic mission has also been in existence in the island since 1859. In 1867 the United States consul at Amoy made a treaty with Tok-a-Tok, a chief of the aborigines of the southern part of the island, by which the safety of foreigners was secured in that district. An attack made on the Protestant and Roman Catholic missions at Feng-shan-hsien in 1868 led the British consul to authorize the occupation of Fort Zelandia and Amping by Colonel Gordon; but his action was afterwards disapproved by the home Government, and the indemnity demanded from the Chinese restored. In 1872 the crew of a Japanese vessel shipwrecked on the coast being murdered by the savages, the Japanese Government sent an expedition to punish the assassins, and a war between China and Japan would have been the consequence if Wade the English ambassador had not succeeded in bringing them to terms,—China agreeing to pay 500,000 taels as compensation to the friends of the murdered men and to purchase the houses, etc., erected by the Japanese, and the Japanese on their side withdrawing their troops and giving up all claims to occupation. According to Mr. Hewlett's report for 1872, the political state of the island is very bad; the official classes, he says, have a proverb "every three years an outbreak, every five a rebellion," and the reason of this instability is to be found in their own rapacity and glaring violations of justice. A more hopeful account is given by Mr. Morrison in 1877; under the enlightened government of Ting, formerly *futai* of Fuh-chow, roads are being constructed throughout the Chinese territory, and other measures adopted for the development of its resources. A telegraph has been laid between Taiwanfu and Takao; and the proposal to make a railway from the south to the north of the island is being seriously discussed. A fort was built at Amping (the port of Tàiwanfu) between 1874 and 1876, and two others at Takao. A scheme is in operation for the military reduction of the east coast districts, and a road is being pushed south from Sauo.

Ravenstein in the *Geographical Magazine*, Oct., 1874.

FORMOSUS, the successor of Stephen V. (or VI.), as pope, first appears in history when, as bishop of Porto, he was sent on an embassy to the Bulgarians. Having afterwards sided with the German faction against John VIII., he was excommunicated, and compelled to take an oath never to return to Rome, or again to assume his priestly functions. From this oath he was, however, absolved by Martin II., the successor of John VIII., and restored to his dignities; and on the death of Stephen V. in 891 he was chosen pope. The Italian faction had chosen Sergius, and the election of Formosus, which was in opposition to an old rule against the translation of bishops from one see to another, had to be confirmed by recourse to violence, but was rendered secure for a time by the success of the arms of Arnulf of Germany. After the withdrawal of Arnulf, Formosus was compelled to grant the imperial crown to Lambert, son of Guido of Italy, but this act did not pacify the Italian faction, and Formosus was only released from very hard straits by the arrival of Arnulf, who captured the city in the end of 895. In the following year Arnulf was crowned emperor by Formosus, but before the death of the latter in May, the excesses of Arnulf and his soldiers had begun to create a strong opposition to the German power amongst all parties in Italy. By Stephen VI. the body of Formosus was disinterred, and treated with contumely as that of a usurper of the papal throne; but Theodorus II. restored it to Christian burial, and at a council presided over by John IX. the pontificate of Formosus was declared valid and all his acts confirmed.

FORRES. See Elgin, vol. viii. p. 122.

FORSKAL, Peter (1736–1763), a celebrated Oriental traveller and naturalist, was born in Sweden in 1736. He studied at Göttingen, where he published a dissertation entitled *Dubia de Principiis Philosophiæ Recentioris*, which gained him some reputation. Thence he returned to his native country; but in 1759 he alienated the good-will of the Government by the publication of a pamphlet entitled *Pensées sur la Liberté Civile*. His acquaintaince with natural history, however, had gained him the friendship of Linnæus, who recommended him to Frederick V. of Denmark. From that sovereign he obtained the title of professor at Copenhagen, and Frederick also appointed him to accompany Carsten Niebuhr in an expedition to investigate Arabia and Egypt. He died of the plague at Jerim in Arabia, July 11, 1763. His friend and companion Niebuhr was entrusted with the care of editing his MSS., and published in 1775 *Descriptiones Animalium, Avium, Amphibiorum, Piscium, Insectorum, Vermium, quæ in itin. Orient. observavit Petrus Forskal*. In the same year appeared also an account of the plants of Arabia Felix and of Lower Egypt, under the title of *Ægyptiaco-Arabica*, which is important as containing the first discussion of the relation of vegetation to climate.

FORST, originally Forsta or Forste, a town of Brandenburg, Prussia, circle of Sorau, is situated on the Neisse, 44 miles S.E. of Frankfort-on-the-Oder. Its principal industries are tanning and the manufacture of woollen cloth; and it has also a considerable cattle trade. Near the town are the ruins of an old castle. Forst was founded in the 13th century, and was burned down by the Hussites in 1430. From 1667 it belonged to the dukes of Sachsen-Merseburg, from 1740 to the palatinate of Saxony, and from 1815 to Prussia. Population in 1875 (including Altforst, united to it in 1874), 14,148.

FORSTER, François (1790–1872), a French engraver, was born at Locle in Neufchâtel, 22d August, 1790. In 1805 he was apprenticed to an engraver in Paris, and he also studied painting and engraving simultaneously in the École des Beaux Arts. His preference was ultimately fixed on the latter art, and on his obtaining in 1814 the first "grand prix de gravure," the king of Prussia, who was then with the allies in Paris, bestowed on him a gold medal, and a pension of 1500 francs for two years. With the aid of this sum he pursued his studies in Rome, where his attention was devoted chiefly to the works of Raphael. In 1844 he succeeded Tardieu in the Academy. He died at Paris, 27th June, 1872. Forster occupied the first position among the French engravers of his time, and was equally successful in historical pieces and in portraits.

Among his works may be mentioned—The Three Graces, and *La Vierge de la légende*, after Raphael; *La Vierge au bas-relief*, after Leonardo da Vinci; Francis I. and Charles V., after Gros; St. Cecilia, after Paul Delaroche; Alfred Dürer and Henry IV., after Porbus; Wellington, after Gérard; and Queen Victoria, after Winterhalter.

FÖRSTER, Friedrich (1791–1868), a German historian, brother of Ernst Joachim Förster the painter, was born at Münchengrosserstädt on the Saale, September 24, 1791. After receiving his early education in the gymnasium at Altenburg, he studied theology at Jena, but subsequently devoted his attention for a time chiefly to archæology and the history of art. On the uprising of Prussia against France in 1813 he joined the army, where he soon attained the rank of captain. At the close of the war he was appointed professor at the school of engineering and artillery in Berlin, but on account of certain democratic writings he was dismissed from that office in 1817. He then became connected with various literary journals, and in 1830 undertook with his brother an art tour in Italy. Shortly after his return he received an appointment at the royal museum of Berlin, with the title of court councillor. Förster was the founder and secretary of the *Wissenschaftlichen Kunstverein* (scientific art union) of Berlin. He died at Berlin, 8th November, 1868.

The following are his principal works:—*Der Feldmarschall Blücher und seine Umgebungen*, Leipsic, 1821; *Friedrich's d. Gr. Jugendjahre, Bildung, und Geist*, Berlin, 1822; *Albrecht von Wallenstein*, Potsdam, 1834; *Wallenstein's Process*, Leipsic, 1844; *Geschichte Friedrich Wilhelms I., Königs von Preussen*, 3 vols., Potsdam, 1834–35; and *Die Höfe und Cabinete Europas im 18ten Jahrh.*, 3 vols., Potsdam, 1836–39. He also wrote a number of popular historical works, the principal of which are *Neuere und neuste preuss. Geschichte*, and *Geschichte der Befreiungskriege*, 1813, 1814, and 1815, both of which have reached several editions; and besides editing an edition of Hegel's works, and adapting several of Shakespeare's and other dramatists' plays for the theatre, he is the author of a number of poems, which were collected and published at Berlin 1838, and of an historical drama, *Gustav Adolf*, 1832. The beginning of an autobiography of Förster was published at Berlin in 1873, under the title *Kunst und Leben*.

FÖRSTER, Johann Georg Adam (1754–1794), an eminent German naturalist and writer on scientific subjects, was born at Nassenhuben, a small village near Dantzic, in November, 1754. His father, Johann Rheinhold Forster, a man of great scientific attainments but an intractable temper, was at that time pastor of the place; the family are said to have been of Scotch extraction. In 1765 the elder Forster was commissioned by the empress Catherine to inspect the Russian colonies in the province of Saratov, which gave his son an opportunity of acquiring the Russian language and the elements of a scientific education. After a few years the father quarrelled with the Russian Government, and suddenly embraced the resolution of proceeding to England, where he obtained a professorship of natural history and the modern languages at the famous nonconformist academy at Warrington. His violent temper soon compelled him to resign this appointment, and for two years he and his son earned a precarious livelihood by translations in London,—a practical education, however, exceedingly useful to the younger Forster, who became a thorough master of English, and acquired many of the ideas which chiefly influenced his subsequent life. At length the turning point in his career came in the shape of an invitation for him and his father to accompany Captain Cook in his third voyage round the world. Such an expedition was admirably calculated to call forth Forster's peculiar powers. He attained no remarkable distinction as an original discoverer or investigator, but his insight into nature was accurate and penetrating; he conceived of her as a living whole, and reproduces her vitality in his animated pages. His account of Cook's voyage is almost the first example of the glowing yet faithful description of natural phenomena which has since made a knowledge of them the common property of the educated world,—a prelude to Humboldt, as Humboldt to Darwin and Wallace. The publication of this great work was, however, impeded for some time by differences with the Admiralty, during which Forster proceeded to the Continent to obtain an appointment for his father as professor at Cassel, and found to his surprise that it was conferred upon himself. The elder Forster, however, was soon provided for elsewhere, being appointed professor of natural history at Halle. At Cassel Forster formed an intimate friendship with the great anatomist Soemmerring, and about the same time made the acquaintance of Jacobi, who inspired him with a mystical spirit from which he subsequently emancipated himself. These were the days of secret societies, masonic lodges, and conventions of illuminati. Forster was for a long time deeply implicated in their proceedings, the purpose of which remains obscure. The want of books and scientific apparatus at Cassel induced him to resort frequently to Göttingen, where he betrothed himself to Therese Heyne, the daughter of the illustrious philologist, a clever and cultivated but heartless woman, who became the evil genius of his life. To be able to marry he accepted (1784) a professorship at the university of Wilna, where he found himself greatly misplaced. The penury and barbarism of Polish circumstances are graphically described in his and his wife's letters of this period. After a few years' residence at Wilna he resigned his appointment to participate in a scientific expedition projected by the Russian Government, and upon the relinquishment of this undertaking became librarian to the elector of Mayence. In 1790 he published his travels in the Netherlands, with special reference to the art of the country—a work displaying the same power of exposition in æsthetic matters as he had previously shown in the description of the aspects of nature. This was his last work. The principality of Mayence was now involved in the vortex of the French Revolution, and Forster unhappily suffered himself to be drawn into a position incompatible either with fidelity to his master the elector, or allegiance to his country. With his liberal sympathies and deficiency in political insight, he might be excused for welcoming the French as deliverers, but in promoting the actual incorporation of Mayence with France, he justly incurred the execration of patriotic Germans, notwithstanding the unquestionable purity of his intentions. Domestic sorrows were added to public calamities: Forster found himself not only deserted by his wife but deprived of his children. It is difficult to determine whether his apparent resignation should be ascribed to romantic self-sacrifice or to the apathy of an exhausted spirit. The situation was nearly the same as that of George Sand's *Jacques*, and the catastrophe not very dissimilar. Forster died suddenly and opportunely, January, 1794, in Paris, whither he had gone as deputy from Mayence in the worst days of the Reign of Terror. His personal character was most amiable; he was high-minded, disinterested, ingenuous to a fault; but he was weak, impulsive, ill-starred throughout his life, and totally unequal to the difficult circumstances in which he ultimately found himself. As an author he stands very high; he is almost the first and almost the best of that valuable class of writers who have made science and art familiar by representing them in their essential spirit, unencumbered with technical details. Schlegel remarks that no other German prose writer carries his reader so far, leaving him not merely enriched with positive knowledge but animated with the passion for further progress; that the books of no other such writer convey so lively an impression of having been composed outside the study in the free air; and that no other is animated by so constant a sense of the infinite perfectibility of human nature.

Forster's writings have been frequently collected. The most important have been mentioned above, but there are numerous minor essays of great value and artistic completeness. His correspondence with his friend Soemmerring has been recently published by Hettner, and is full of interest. The biography by Moleschott is very agreeably written, but is rather a delineation of a typical naturalist than of the actual man, and its account of Forster's political career is vitiated by the writer's own deficiency in patriotic feeling. The other side of the question is presented with unnecessary asperity in Klein's *George Forster in Mayence*. There are excellent critical estimates by Schlegel and Gervinus, the latter prefixed to the seventh volume of Forster's writings. (R. G.)

FORSTER, JOHN (1812–1876), an English historian, biographer, journalist, and critic, was born April 2, 1812, at Newcastle, where his father, a member of the Unitarian Church, followed the occupation of a butcher. He was well grounded in classics and mathematics at the grammar school of his native town, and gave early promise of future distinction. After a brief residence at Cambridge he removed in 1828 to London, where he attended law classes in connection with the recently founded university, but devoted himself chiefly to literary pursuits. The earlier productions of his pen were contributed to various liberal papers, particularly to *The True Sun*, *The Morning Chronicle*, and *The Examiner*. As literary and dramatic critic for the last-named journal, he from the outset showed much conscientiousness, discrimination, and tact, and the influence of his powerful individuality soon made itself strongly felt. He had not long passed his twentieth year when the publication of his *Lives of Eminent British Statesmen* began. This work, originally undertaken for Lardner's *Cyclopædia*, and published separately in 1840 under the title of *The Statesmen of the Commonwealth of England, with a Treatise on the Popular Progress in English History*, was immediately recognized as a work of great interest and value, entitling its author to high literary rank. Thenceforward he was a prominent figure in that distinguished circle of literary men which included such names as Bulwer, Talfourd, Fonblanque, Landor, Carlyle, Dickens. In 1843 he was called to the bar by the benchers of the Inner Temple; but while highly valuing this honorable connection with the legal profession, he never became or sought to become a practising lawyer. His energies were mainly devoted to laborious historical investigations, while relaxation was sought chiefly in lighter forms of literary activity. For some years he edited the *Foreign Quarterly Review;* in 1846, on the retirement of Charles Dickens, he took charge for almost a year of the *Daily News;* in 1847, on the resignation of Albany Fonblanque, he became editor of the *Examiner*, and this post he retained till 1856. From 1836 onwards he contributed to the *Edinburgh*, *Quarterly*, and *Foreign Quarterly Reviews* a variety of articles, some of which were republished in two volumes of *Biographical and Historical Essays* in 1858. In 1848 appeared his *Life of Oliver Goldsmith*, which, especially as revised and improved in a second edition (1854), has taken an acknowledged place as one of the most admirably executed biographies to be found in the whole range of English literature. Continuing his original researches into English history at the period of the Revolution, he published in 1860 two volumes, respectively entitled *Arrest of the Five Members by Charles I.—A Chapter of English History rewritten*, and *The Debates on the Grand Remonstrance, with an Introductory Essay on English Freedom*. These were followed by his *Biography of Sir*

John Eliot, published in 1864, an elaborate and finished picture from one of his earlier studies for the *Lives of the Statesmen*. In 1868 appeared his biography of his friend Walter Savage Landor. For several years he had been collecting materials for a life of Swift, but his studies in this direction were for a time suspended in consequence of the death of Charles Dickens, with whom he had long been on terms of intimate friendship. The first volume of Forster's *Life of Dickens* appeared in 1871, and the work was completed in 1874. Towards the close of 1875 the first volume of his *Life of Swift* was published; and he had made some progress in the preparation of the second, when he was seized with an illness of which he died on the first of February, 1876. He lies buried in Kensal-Green Cemetery, where a just and discriminative inscription tells that he was "noted in private life for the robustness of his character and the warmth of his affections; for his ceaseless industry in literature and business, and the lavish services which, in the midst of his crowded life, he rendered to his friends; for his keen appreciation of every species of excellence, and the generosity of his judgments on books and men." In 1855 Forster had been appointed secretary to the Lunacy Commission, and for some years after 1861 he held the office of a commissioner in lunacy. In 1860 he received the honorary degree of LL.D. from the university of Edinburgh. His valuable collection of manuscripts, along with his books and pictures, was bequeathed to the South Kensington Museum.

FORT DE FRANCE, formerly PORT ROYAL, the capital of the French island of Martinique, one of the smaller Antilles, is situated on the west coast of the island, on the north side of a well-sheltered bay. It is the residence of the governor, and possesses a court of justice and a chamber of commerce. The harbor, which is commanded by a fort, is good and safe, and connected with it there is a floating dock and a repairing dock. The town possesses sugar works, and its chief exports are sugar, coffee, and rum. Its trade will be considerably increased by the railway to St. Pierre. During the war with France Port Royal was for a time the headquarters of the British West Indian fleet. The population of the town is about 11,500.

FORTESCUE, SIR JOHN, an eminent English lawyer in the reign of Henry VI., was descended from an ancient family in Devonshire, and, in all probability, was born at Norris, near South Brent in Somersetshire, towards the close of the 14th century. He was educated at Exeter College, Oxford. During the reign of Henry VI. he was three times appointed one of the governors of Lincoln's Inn. In 1441 he was made a king's sergeant at law, and in the following year chief justice of the king's bench. As a judge Fortescue is highly commended for his wisdom, gravity, and uprightness; and he seems to have enjoyed great favor with the king, who is said to have given him some substantial proofs of esteem and regard. He held his office during the remainder of the reign of Henry VI., to whom he steadily adhered; and having faithfully served that unfortunate monarch in all his troubles, he was attainted of treason in the first parliament of Edward IV. When Henry subsequently fled into Scotland, he is supposed to have appointed Fortescue, who appears to have accompanied him in his flight, chancellor of England. In 1463 Fortescue accompanied Queen Margaret and her court in their exile on the Continent, and returned with them afterwards to England. During their wanderings abroad the chancellor wrote for the instruction of the young Prince Edward his celebrated work *De laudibus legum Angliæ*. On the defeat of the Lancastrian party, he made his submission to Edward IV., from whom he received a general pardon dated Westminster, October 13, 1471. He died at an advanced age, but the exact date of his death has not been ascertained.

Fortescue's masterly vindication of the laws of England, though received with great favor by the learned of the profession to whom it was communicated, did not appear in print until the reign of Henry VIII., when it was published by Whitechurch in 16mo, but without a date. In 1516 it was translated by Mulcaster, and printed by Tottel; and again in 1567, 1573, and 1575, and also by White in 1598, 1599, and 1609. It was likewise printed, with Hengham's *Summa Magna et Parva*, in 1616 and 1660, 12mo; and again with Selden's notes in 1672, in 12mo. In 1737 it appeared in folio; and, in 1775, an English translation, with the original Latin, and Selden's notes, besides a variety of remarks relative to the history, antiquities, and laws of England, was published in 8vo. Waterhouse's *Fortescue Illustratus*, which appeared in 1663, though prolix and defective in style, may be consulted with advantage. Another valuable and learned work by Fortescue, written in English, was published in 1714, under the title of *The Difference between an Absolute and Limited Monarchy, as it more particularly regards the English Constitution, and accompanied with some remarks by John Fortescue Aland, of the Inner Temple, London*; and a second edition with amendments appeared in 1719. In the Cotton Library there is a manuscript of this work, in the title of which it is said to have been addressed to Henry VI.; but many passages show plainly that it was written in favor of Edward IV. Of Fortescue's other writings, which were pretty numerous, the most important are—1. *Opusculum de Natura Legis Naturæ, et de ejus censura in successione Regnorum Supremorum*; 2. *Defensio juris Domus Lancastriæ*; 3. *Genealogy of the House of Lancaster*; 4. *Of the Title of the House of York*; 5. *Genealogiæ Regum Scotiæ*; 6. *A Dialogue between Understanding and Faith*; 7. *A Prayer Book which savors much of the Times we live in.* In 1869 his descendant, Lord Clermont, printed for private distribution *The Works of Sir John Fortescue, now first collected and arranged*, and *A History of the Family of Fortescue in all its branches* (see *Lambeth Review*, 1872).

FORTH, one of the largest rivers in Scotland. It is formed of two streams rising to the north of Ben Lomond (one of them passing through Loch Chon and Loch Ard), which unite above Aberfoyle. The river flows eastward in a direct course for above 100 miles, receiving in its progress the Goodie, the Teith, and the Allan above Stirling, and below it the Devon, the Carron, the Avon, the Almond, the Leith, the Esk, the Leven, the Tyne, and others; and it discharges itself into the German Ocean in about 56° 10′ N. lat. The windings or "links" of the Forth above and below Stirling are extremely tortuous. From its junction with the Teith to the "carse" or alluvial plain below Gartmore they extend about 28 miles, although the distance in a direct line is only about 20. From Stirling harbor to Alloa, where it widens into an estuary, the length of the river is 10½ miles, though the distance in a straight line is not more than 5. From Grangemouth to North Queensferry the depth increases in the first mile from 10 to 15 feet, in the second to 25, and in the third mile to 53 feet, while the remaining part of the distance—7 miles, including the great anchorage of St. Margaret's Hope—has a depth generally of about 60 feet at low water. At Queensferry the firth is 2 miles wide; between Dysart and Aberlady about 12; and between St. Abb's Head and Fifeness, where it joins the German Ocean, it is from 35 to 40 miles. Near Queensferry, between Inchgarvie and the North shore, it deepens to 37 fathoms. The bed of the river consists to a great extent of mud,—the depth of the deposit in some places being upwards of 200 feet; and there are extensive alluvial formations along the lower part of its course and in the upper reaches of its estuary. The tides are felt 4½ miles above Stirling, and at Stirling harbor the spring tides rise 7 feet 9 inches. At Leith and Kinghorn their average height is 17½ feet. Steamers go as far up the river as Stirling,—the only important obstructions to the navigation between that town and Alloa, the "Town Ford" and the "Abbey Ford," having been removed since 1843. The shallowness of the channel seems to have been occasioned by the practice in vogue from 1732 among the Stirlingshire proprietors of using the river to carry off the peat from their lands; Mr. Drummond of Blair-Drummond, for example, between 1783 and 1839 floated away upwards of 1000 acres of this substance. Further down in the firth the principal obstructions are the Drumsands near Cramond and the Sand-end to the east of Burntisland harbor. The anchorages in the firth are excellent; and it thus forms the most important harbor of refuge to the north of the Humber. Several of its ports carry on a large foreign trade, more especially Leith, Granton, Bo'ness, and Grangemouth. The fisheries of herring, white fish, and salmon are all of great economical importance, not only giving employment to a considerable local population, but attracting English and even foreign fishermen. The traffic between the two sides of the firth has been an object of legislation since 1467. Both the principal ferries—that between North and South Queensferry, and that between Granton and Burntisland—are now in the hands of the North British Railway Company. In connection with their system they have undertaken to construct a magnificent viaduct across the firth, the foundation stone of which was laid on the 30th of September, 1878. Thomas Bouch, the engineer entrusted with the enterprise, has practically revived a plan proposed as early as 1818 by James Anderson. The bridge is to cross a little to the east of the present line of traffic between North and South Queensferry, advantage being taken of the small island of Inchgarvie, which lies about mid channel. Its most striking features will be two spans of 1600 feet, constructed on the suspension principle at a height of 150 feet above high water of spring tides. In order to secure sufficient stability against the lateral pressure of the winds, which sometimes blow with great violence in the firth, these central portions will be split into two branches, each about 14 feet wide, which will lie 100 feet apart, but be bound together by horizontal braces. Both the great spans will be laid on a dead level, but the shoreward sections will have gradients of about one in 77 and one in 80. The total cost is estimated at £1,250,000, and it is expected that the works will be completed in 1882.

FORTIFICATION is the art of strengthening, by works of defence, positions in which it is proposed to place troops so as to render them secure from the attack of an enemy. Such positions may contain within them towns, dockyards, arsenals, and ports, or may serve merely for shelter for an army in the field; but the object to be attained is always the same, and the works of defence are so disposed round the position that, while they offer the greatest obstacles to the advance of their assailants, they afford the utmost shelter to their defenders. Fortification is, in short, the art of enabling the weak to resist the strong.

Various terms have been adopted in connection with the general term of Fortification, but none of them are of much use in considering the subject, and some may lead to error, by inducing the engineer to restrict himself under some circumstances to a very limited view of his subject. Thus, Fortification Natural and Fortification Artificial imply a useless distinction, as every engineer must avail himself of the natural advantages or obstacles of ground, as well as of the obstacles his science and genius enable him to add to them; and thus in every Fortification nature and art must act together. Fortification Regular and Fortification Irregular are defective terms, as no Fortification can possibly be regular unless it should so happen that the ground it occupies, as well as the ground surrounding it on all sides, is uniform in level and general character. Again Fortification Permanent and Fortification Field or Temporary have reference only to the immediate object of the works, or to the application of the science, and in no way affect its principles, which remain the same whether the work is a simple earthen intrenchment, or a great fortress surrounded by masonry walls. Fortification Offensive and Fortification Defensive are, however, of all terms the most objectionable, since they imply a contradiction to fact, for the perfection of defence depends as much on its active offensive operations as on the protection of its covering works, while the perfection of attack depends as much on the skill with which its passive protective works are pushed forward as on the fire of its batteries.

The principles of Fortification then should be studied unshackled by any of these distinctions, and the engineer should apply his means to his end, using without restriction the works best suited to his purpose; and it is in this way that the study of the subject will be here treated.

Elementary Fortification.

It is desirable to examine the exact meaning of technical words, in order to acquire a distinct notion of the ideas they were intended to convey, and to obtain a glimpse of the historical progress of the science in which they are used. Fortify, Fortifications, Fortress, Fort, are all derived from *fortis*, strong; and the idea the first two convey is that, by artificial arrangement, additional strength is bestowed upon one combatant over another, or upon one party of combatants over another party. A rock, the trunk of a tree, a bank of earth, or any natural object, which shelters the body of a man from the missiles of his opponent whilst it leaves him free to discharge his own, may be considered the simplest form of fortification.

A bank of earth, when reduced to the requisite thickness, and moulded into proper form, with such slopes as the particular tenacity of the earth may require to insure stability, or which the intended direction of the fire over its summit may render necessary, becomes a Parapet, so called from the Italian words *para*, a defence or guard, and *petto*, the breast, or, in English, a breastwork. If the Breastwork or Parapet be made only sufficiently high to permit the soldier to fire over it, he will be exposed after firing, and will be forced to crouch in order to obtain cover. The parapet is therefore made high enough to cover the soldier when standing up so that he can load with ease and security, and can move with safety from place to place behind it. This increased height renders it necessary to introduce a Banquette or step (accessible by an easy slope), standing upon which the soldier can fire over the parapet and from which he can retire by the interior slope to the lower ground behind it; the name Banquette is derived from *banchetta*, a little bench or step. As Parapets are usually formed artificially, the earth for their construction is derived from a ditch, which being dug immediately in front of and parallel to the parapet, forms by its depth an additional obstruction to an advancing enemy. Ordinary intrenchments are formed of a simple parapet and ditch, but in more important outworks and in fortresses the height is further augmented by elevating the parapet on another mound of earth called the Rampart (*riparo* in Italian), and as this additional height requires a greater quantity of earth, the ditch is made both wider and deeper. By these means the difficulties of attack are increased, additional cover is given to the magazines or other buildings within the fortress, and the command over the country is raised and improved in efficiency, by elevating the soldier so that he can see over the many minor obstacles which would otherwise restrict his field of view.

Some writers, regarding the presence or absence of the rampart as the main distinction between permanent and temporary works, have proposed to call the former Rampart or Town Fortification, the latter Parapet or Field Fortification; but this distinction is not of universal application, and the more ordinary divisions of Permanent and Field Fortification better indicate the nature of the works and the objects for which they are intended.

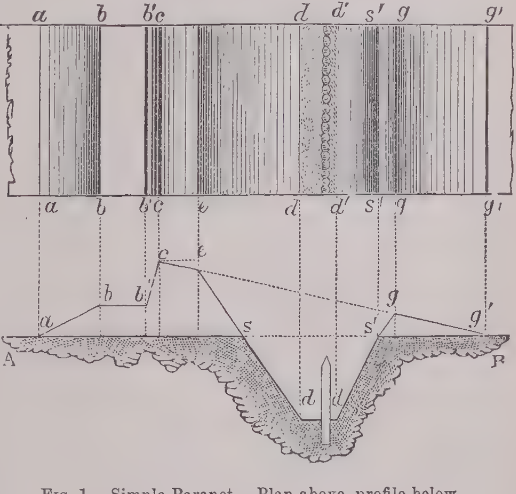

Fig. 1.—Simple Parapet. Plan above, profile below.

In order to study efficiently the combinations of these simple elements, with a view to form from them works of defence, it is necessary that we should know the manner in which such works are represented on paper. As in architecture, of which in earlier times fortification was only a military branch, this is effected by the plan, the section, and the elevation, of which the first two are the most important. The plan of a work is the orthographic projection of the lines of intersection of the planes of its slopes on the plane of construction. The elevation is a similar projection on a vertical plane. The section or profile is made on a plane perpendicular to the lines of intersection of the planes or slopes, and therefore represents the traces of these planes on the sectional plane. Fig. 1 represents a small portion of a simple parapet in plan and profile, and leads to the following explanation of terms:—

In the plan, *cc* represents the crest of the parapet or highest ridge line of the work. In delineating the outline of a work, it is this line which is always drawn; it is called the "trace." Between *cc* and *ee* is the superior slope; between *ee* and a line parallel to it through *s* is the exterior slope, prolonged in this case to the bottom of the ditch *dd*, being continuous with the escarp *sd*; *gg* is the crest of the glacis, or ridge of a slightly elevated mound of earth raised on the exterior edge of the ditch, or counterscarp, and sloping gently outward, so that the assailants passing over its surface may be in the prolongation of the superior slope of the parapet, and therefore in the line of fire from its crest; by its elevation the glacis increases the amount of descent into the ditch. Within the crest of the parapet are seen the interior slope of the parapet, bounded by *b′b′*, the banquette, between *b′b′* and *bb*, and the interior slope of the banquette, bounded by *aa*.

Relief.—This term is adopted to indicate the height of any point of the work either above the plane of construction, which is sometimes the plane of site, when it is called constructive relief, or above the bottom of the ditch, when it is called absolute relief. The absolute relief is a very important datum, as it expresses the total obstruction offered by the parapet and ditch to the ascent of the assailant, and it has a bearing on the regulation of the length of lines, which mutually defend each other. The Relief of a work is the relief of the crest of its parapet. The Command of a work is the height of the crest of its parapet, either above the plane of site if horizontal, or above any point of that plane specially referred to, or above the crest of the parapet of any other work in front of it; the difference of height, therefore, between the crest of the parapet in fig. 1 and the crest of the glacis is the command of the parapet over the glacis; in the one case the command is absolute, in the other relative.

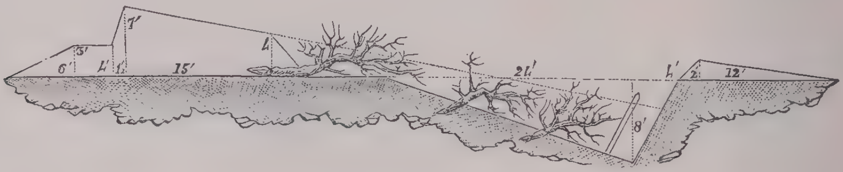

Fig. 2.—Arrangement of Abattis.

But after all a simple parapet and ditch afford only temporary protection, and it is necessary to stop an enemy as he advances to them by placing obstacles in his path which shall retain him as long as possible under the fire of the works opposed to him either in front or in flank. In the profile in fig. 1, the simplest form of such an obstacle, viz., a Palisade, is shown. When, however, in combination with direct fire only, as in the figure, palisades check an enemy but for a short time, and are principally useful as affording more time to the defenders. Indeed in any combination of defence palisades are now of much less value than formerly, as they are readily destroyed by indirect fire, and by the new explosives which are more portable and far stronger than gunpowder; they are mainly used in closing the gorges of temporary works. Many other obstacles may, however, be so arranged as to assist materially in rendering simple direct fire more effective.

Abattis are formed of trees cut down, and arranged side by side with the branches interlaced outwards, and the stems inwards; the branches should be freed from foliage, and their ends cut sharp. They may be arranged in one or more rows, so that the fire from the parapet shall sweep along their summits, their stems being firmly fastened by pickets to the ground and partly buried in it; an enemy would suffer great loss whilst attempting to remove them under fire. The best abattis are formed of good-sized growing trees. The trunks are partially cut through a little above the ground, and the trees are bent down and securely fastened to the ground and to one another by pickets and iron wire.

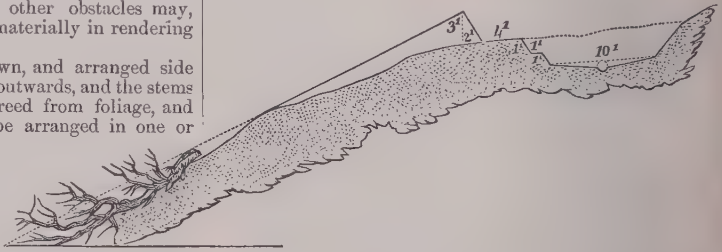

Fig. 3.—Simpler arrangement of Abattis.

Fig. 2 exhibits an arrangement of Abattis; and it will be observed that in this profile the exterior slopes of the parapet and the escarp are formed into one gentle slope, whilst the counterscarp retains its ordinary slope. By this modification the difficulty of descending into the ditch remains as before, and the sloping pickets in front of the abattis prevent the assailants from clearing it away. In simple inclosed works, such as redoubts, and in lines, the defence frequently depends on direct fire alone; and in these cases a work of the profile here figured with obstacles would be far more effective in checking an enemy than a work of ordinary profile without obstacles, and would render it impossible that a watchful garrison should be surprised; and this is a very important consideration, as a vigorous and bold enemy could scarcely be stopped if he had succeeded in arriving at the foot of the escarp unchecked.

Fig. 3 exhibits another arrangement formed only of large branches securely picketed down to the ground. In this case the form of the ground is taken advantage of, and the profile of the defensive line is modified, a trench being cut out behind it, and the banquette being formed on the surface of the ground. By simple arrangements of this kind, it will often be possible to carry defensive lines over a large extent of ground in a short period of time, and to obtain more effective defence by taking advantage of the natural facilities of the ground than by the construction, with a great expenditure of labor and time, of elevated works, not so well fitted to sweep the surface of the ground, and to act upon the obstacles placed to check the progress of the assailants.

Chevaux-de-frise.—The Cheval-de-frise (fig. 4) is a substitute for an abattis. It consists of a strong horizontal beam, 12 feet long and 9 inches square, through which are passed strong lance-like rods of wood or iron, sharp at both ends, and about 6 inches apart. Several of these may be joined together by rings and hooks with which the ends of the beams are fitted.

Chevaux-de-frise require a considerable amount of skilled labor in their construction; hence they can only be employed in limited quantities for limited objects. They are employed for temporary purposes, *e.g.*, as barriers to the entrance of a work, across a road or street, in positions where they can be easily removed when the communication is required to be used. They have the disadvantage of being removed or destroyed without much difficulty. It is, however, usual to keep as articles of store iron chevaux-de-frise, so made that the parts are separable for convenience of package and transport. If planted at the bottom of a hollow, exposed to direct fire, so that they must either be pushed uphill forward or pulled downhill backward, and

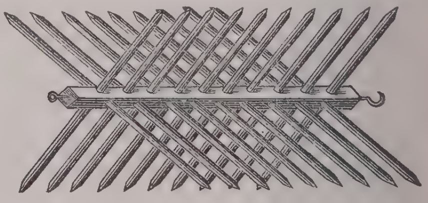

Fig. 4.—Cheval-de-frise.

securely fastened by chains to the ground or to upright posts, they form a very formidable obstacle.

Fraises are palisades placed in a horizontal or nearly horizontal position. They are of wood or iron, and are usually made about 10 feet long and 15 inches thick, bound together by two ribands, nailed above and below them and buried in the ground, without which they would be more easily torn away. They are fixed both on the counterscarp and on the escarp. When on the escarp they are inclined downwards, and the berm is cut away; when on the counterscarp, they are inclined upwards. On the counterscarp they are safe from direct fire, and retain an enemy outside the ditch.

Fig. 5 represents, in section, a row of fraises on the escarp. In this profile the ordinary banquette for musketry is represented by dotted lines below a wider terreplein, formed for artillery to fire over the parapet, or "*en barbette*," as it is usually called; but this will be more fully explained below.

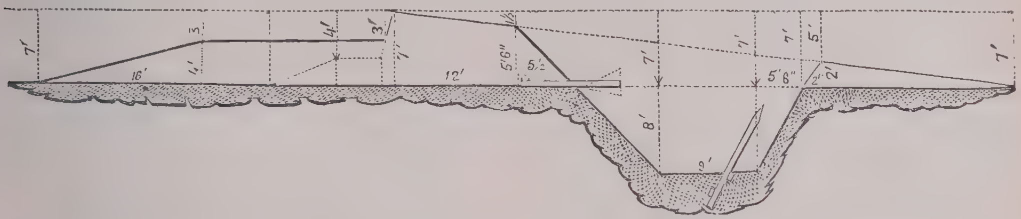

Fig. 5.—Profile showing Fraises on the Escarp.

The "Wire Entanglement" is the best and most easily made of hasty accessory defences. It can be applied everywhere, and can be made by anybody; the material of it is carried in a small compass; it does not interfere with the fire of the defence; it cannot be seen from a distance; and artillery has little effect upon it. A form of wire entanglement is shown in fig. 6. Stout stakes are driven into the ground 5 feet apart, and disposed in rows chequer-wise; strong wires are wound round them about 1 foot 6 inches above the ground, crossed diagonally by finer wires. No entanglement should be less than 36 feet in depth. The wires should hang slackly from their supports, as when strained they are easily divided by a sword-blow, and the stakes should vary in height. 14 B.W.G. steel wire is very suitable for the thicker wires; it is strong and weighs only 90 lb per mile. Wire entanglements in the bottom of a ditch offer a strong resistance. They are well placed in the slopes of the glacis and counterscarp and on the berm; but they are most effective when interwoven with bushes and trees in the defence of woods.

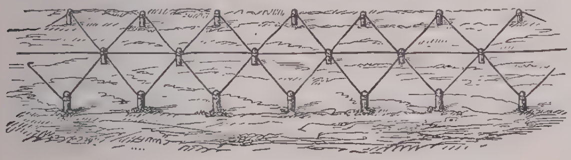

Fig. 6.—Wire Entanglements.

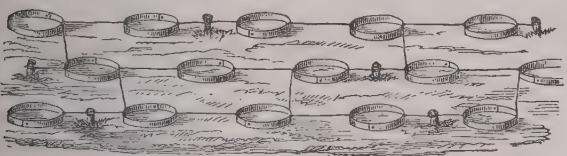

Fig. 7.—Gabions as an Entanglement.

Iron "band Gabions," when disposed as in fig. 7, form a good entanglement. The bands are buttoned and placed in lines 4 feet apart, and connected together by strong wires passing through the bridging holes.

Crows' Feet (fig. 8) are made of iron with four points so arranged that one shall always project upward in whatever manner they may be thrown on the ground; the points are either 2 or 4 inches long. Crows' feet are *sown* over a space about 12 feet broad. Troops coming suddenly, and in the dark, on these obstacles, would be much annoyed by them. They are most effective against cavalry, and were formerly much used,—more so than now.

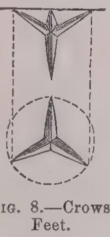

Fig. 8.—Crows' Feet.

Trous-de-loup are holes in the ground in the form of an inverted cone or square pyramid, the sides of which are as steep as is consistent with the stability of the soil. They are made 6 or 8 feet in diameter and 6 feet deep, so that an enemy cannot use them as shelter pits to fire from. At the bottom is fixed a sharp stake 3 feet long, or the branch of a tree cut into sharp points, or a number of smaller sharp pickets, or a quantity of crows' feet. Fig. 9 shows, in plan and section, the arrangement of trous-de-loup proposed by Wenzel.

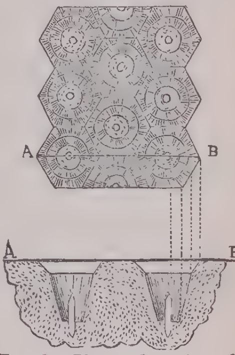

Fig. 9.—Plan and section of Trous-de-loup.

If along the line of a position, either on the glacis or on the escarp (when gradually sloped as in fig. 2), small trees or shrubs are planted, they can be on an emergency cut down, and with the points of their stumps sharpened they would become very annoying to an assailant. Harrows and many other substitutes can also be used; indeed every expedient which ingenuity can suggest should be adopted by the engineer to check the progress of an advancing enemy, and to delay him as long as possible under fire.

Stockades.—Before proceeding to the investigation of the principles which should regulate the relief and thickness of ordinary parapets, viewed in reference to simple defensive lines and to direct fire, it is right to notice the "Stockade" as a substitute, and in some circumstances an advantageous substitute, for a parapet. The Stockade is formed of one or more rows of stout palisades, and in its simplest form is thus constructed. A row of very strong palisades, usually pointed at the top, from 9 to 12 inches in diameter, is fixed deeply in the ground, with intervals of about 3 inches between the palisades. These intervals are filled by smaller palisades cut square at the top—every alternate palisade being shortened 4½ inches, so that the open space above it may be used as a loophole. A stout riband nailed horizontally to the upper ends of the palisades strengthens the construction materially.

Such a Stockade is shown in plan, elevation, and section in fig. 10; it has a banquette of earth, which may be replaced when desirable by a wooden step. By cutting out the triangular portion shown in the section, and throwing the earth up against the front of the palisades, as indicated by the dotted lines, an exterior slope and escarp are formed which keep an enemy constantly in view. A stockade of this description placed close to the edge of a steep bank, has this great advantage over a parapet, that the men behind it have a more effective command of the ground before them when firing through the loopholes than they could possibly have when firing over a parapet. It is here supposed that artillery fire cannot act directly against the stockade, but artillery may possibly be placed to act against it in a longitudinal direction, or, as it is termed, to enfilade it, and in this case the line of stockade should be interrupted by traverses, which are usually banks of earth placed transversely to the line they are intended to protect from such artillery fire. Fig. 11 shows a stockade of this description applied to the defence of precipitous ground. When stockades are formed into inclosed works, they are called "Tambours."

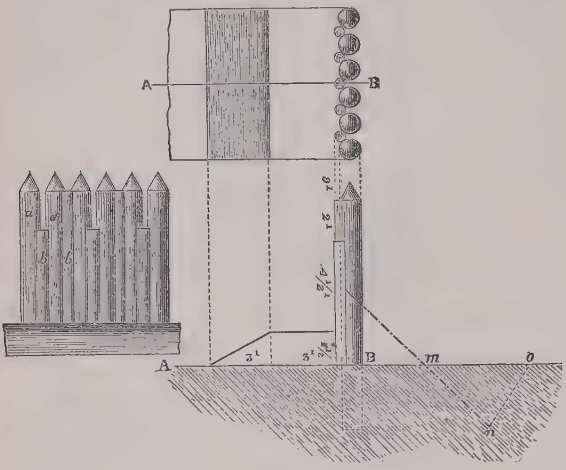

Fig. 10.—Plan, elevation, and section of Stockade.

Under some circumstances it may be desirable to throw an ordinary parapet forward to the edge of a bank, the slope of which supplies the function of escarp, and hence to dig the ditch behind instead of before it, as in fig. 12, where it will be also observed that the slope of the banquette is broken into two steps, the tenacity of the earth when first excavated allowing it to stand firm; the principle of this excavated form of structure is adopted in sunken batteries. Sometimes the object of the parapet is merely cover and not active defence, in which case the banquette is omitted as in fig. 13, and the work is called an "Epaulement." In this profile it will be observed that a space is left between the face of the epaulement and the internal ditch. Such a space should always be left, whether the ditch is within or without, when the work to be formed is of any considerable elevation, as it affords a stage upon which the builders can stand, and lessens the height to which the diggers have to throw the earth from the ditch; it is very important to keep this space clear by throwing forward or backward the earth as quickly as it is raised. The distinguishing characteristic of an able engineer is the power of varying his appliances—thus in his hands the abattis may become the fraise, or may take the place of the palisade, as in fig. 14. If this be not borne in mind, evil rather than good may result from adherence to systematic instruction; as the engineer who has acquired a knowledge of one contrivance may be found crippled by his constant efforts to conform to it rather than to seek some other better fitted to the circumstances of the case. In this profile a berm is represented, as it would be difficult to arrange the abattis and to build the parapets without it.

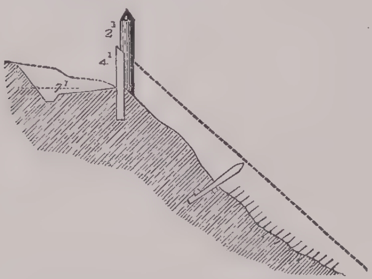

Fig. 11.—Stockade on steep ground.

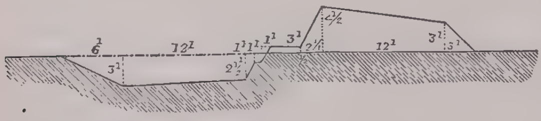

Fig. 12.

The arrangement of the trous-de-loup, combined with stakes driven into the ground is shown in fig. 15, an advanced glacis having been formed of the earth thrown out of the excavations. The ditch is in this case triangular; and it is scarcely necessary to add that the particular form of ditch must be determined by the nature of the ground, remembering that the contents of the ditches must supply material for the parapets; and their depth, as it adds to the difficulty of assault, should not be diminished except from necessity.

After these preliminary remarks, the student should be prepared to enter on the consideration of Field Fortification.

Rules for determining the Dimensions of Parapets.

Determination of the Relief of a Parapet.—First, where the ground is horizontal,—for the protection of troops in a normal position. The minimum for a simple parapet may be here stated at 6 feet 6 inches, as a musket ball would penetrate the parapet for a few inches below its crest, and the maximum at 8 feet, a height which gives the defenders perfect security under almost every circumstance of fire, including that from mounted soldiers.

Defilade.—Secondly, where the ground is uneven, and it is necessary to defilade the work from a point or points which command it.

Fig. 16 explains the first case, in which the points A, B, C, are on the same level, the distance AB being the space intended to be protected by the parapet at C. The line CF represents the supposed normal height at which it is presumed the assailants may fire, in this case 8 feet; BE will be the same; and AD cut by the line drawn from F to E will be 8 feet.

In fig. 17 A, B are still considered to be in one horizontal plane, but C is considerably elevated; and hence, adopting the same data as to height, and drawing the line FE and the line CB parallel to it, AD, or the height of the parapet, is equal to AI + ID,—ID being equal to BE, or CF, or N, the normal height. Calling also AB, or the distance to be covered, d, AH, or the distance from the commanding point, D; and HC, or the height of C above A and B, H,—we have AI : HC : : AB : HB; or AI : H : : $d : d + \mathrm{D}$; and hence

$$\mathrm{AI} = \frac{d}{d+\mathrm{D}} \cdot \mathrm{H}, \text{ and } \mathrm{AD} = \mathrm{N} + \frac{d}{d+\mathrm{D}} \cdot \mathrm{H} \quad . \quad . \quad . \quad (1);$$

so that the necessary height of the parapet increases as the height of the commanding point increases, or as the distance AB to be defiladed increases, and diminishes as the distance from the commanding point increases. Taking D = 600 ft., d = 30 ft., H = 60 ft., then $\mathrm{AI} = \frac{60}{21}$, or 2 ft. 10 in., and AD, the height of the crest of the parapet = 8 ft. + 2 ft. 10 in. = 10 ft. 10 in.; or taking D = 1200 ft., or 400 yards, then AD = 9 ft. 6 in.

Fig. 18 represents A lower than B by a quantity = AO = GH = h; hence AD = AO + OI + ID, and $\mathrm{OI} = \frac{\mathrm{OB.CG}}{\mathrm{BG}} = \frac{d}{\mathrm{D}+d}(\mathrm{H}-h)$,

$$\text{or} \qquad \mathrm{AD} = \mathrm{N} + h + \frac{d}{\mathrm{D}+d} \cdot (\mathrm{H}-h) \quad . \quad . \quad . \quad . \quad (2);$$

which shows that the deeper A is sunk below B and C the more elevated must be the parapet, and hence that this is a very unfavorable condition of parapet. For example, let A be 2 ft. below B, and all other data the same as before, then $\frac{d}{\mathrm{D}+d} \cdot (\mathrm{H}-h)$ = 2 ft. 9 in., and AD = 8 ft. + 2 ft. 9 in. + 2 ft. = 12 ft. 9 in.; or when D = 1200 ft., AD = 11 ft. 4 in.; and if it should be necessary to defilade a distance of 90 ft. instead of 30, the heights of the parapet would necessarily become 18 ft. 8 in., and 14 ft. 2 in.

Again, in figure 19, A is higher than B, and C is lowest of all; and if H still represents the difference of level of A and C, and h the difference of level of A and B, then

$$\mathrm{AD} = \mathrm{N} - h - \frac{d}{\mathrm{D}+d} \cdot (\mathrm{H}-h) \quad . \quad . \quad . \quad . \quad (3);$$

and, of course, so far as concerns the height alone of the parapet, this is the most favorable condition of all.

Any other case is easily resolvable by one or other of the formulæ;—thus, when A and C are on the same level, and B higher than A, H is 0, and equation (2) becomes $AD = N + h - \frac{d}{D+d} \cdot h$. And in equation (3), if B be higher than A, h becomes positive,

and $$AD = N + h - \frac{d}{D+d} \cdot (H + h) \quad . \quad . \quad . \quad . \quad (4);$$

or if h be 0, A and B being on the same level, $AD = N - \frac{d}{D+d} \cdot H$.

In equation (4), if the station C, though below A and B, falls between the horizontal line drawn through A and the line BR, or BA be prolonged till it cuts the surface of the ground sloping from B towards D, then $\frac{d}{D+d} \cdot (H + h)$ is less than h, and AD is greater than N; but should C be below the line BR, then $\frac{d}{D+d} \cdot (H + h)$ is greater than h, and AD is less than N; or, in other words, should the line of defilade passing through BA meet the ground at R within the prescribed limits of defilade, or the effective ranges of musketry and artillery, which may be now assumed as 800 yards for the first and 3000 yards for the second, then if the point C be above that line the parapet at A must be made higher than the normal height, and if below it may be made lower. A comparison of the examples under equation (2) will exhibit the great disadvantage to the defenders of simple lines of having any ground near to their own moderately elevated, and care should be therefore taken either to occupy such ground or to throw back the lines opposite to it as far as possible, and, should it have the character of a ridge, to bring some portion of the fire of the lines to act in the direction of its length. The space AB to be defiladed must depend upon circumstances; the minimum, to allow safe communication for the troops behind and actually defending the parapet, ought not to be less than 30 feet, but when it is necessary to draw up troops behind the parapet it ought not to be less than 90 feet; in cases of double lines or of inclosed works the distance must of course vary, as the object will be to protect, not only the troops near to the enemy from a direct fire, but the troops arming the more distant parapet from a reverse fire. In assuming the normal height as 8 feet, on the supposition that protection is required from the fire of mounted soldiers, a condition is assumed which is not generally likely to occur in the attack of intrenchments. Nevertheless, the command of a work should be sufficient to cover the defenders standing on the ground inside. Infantry are assumed to be 6 feet high, and to protect them, within a reasonable distance of the parapet, from projectiles clearing the crest and tending downwards in the latter part of their trajectory, the command of a parapet on level ground should be at least 8 feet. Shrapnel fire being effective at 3000 yards, and the elevation of the heaviest gun of position for a range of 3000 yards being 7°, the balls clearing an 8-feet parapet will strike the ground 18 yards in rear of the crest of the parapet. In equation (3), and in one case of (4), as explained, the height of the parapet becomes less than N, but should the diminution extend so far as to reduce the height of the parapet below 7 feet, the relief should be restored to its proper amount by excavating the ground behind the parapet, or, in other words, forming a terreplein below the level of the plane of site. In a similar manner, in equation (2), and in one case of (4), where the parapet becomes greater than N, it would be very inconvenient to augment the height above 12 feet, and it is preferable therefore to excavate behind the parapet, whenever the defilade requires so great an increase of height.

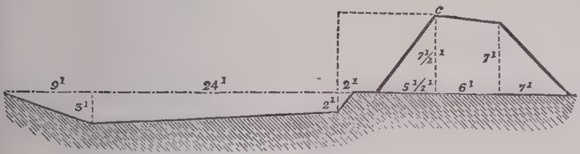

Fig. 13.—Epaulement.

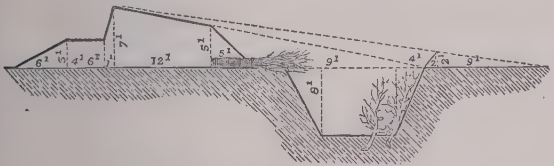

Fig. 14.—Use of Abattis as Fraise and Palisade.

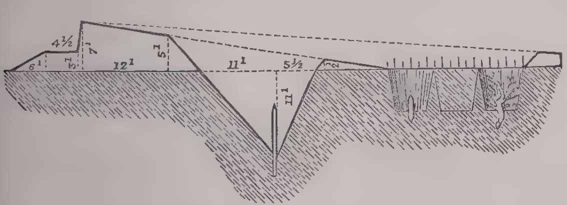

Fig. 15.—Trous-de-loup in front of triangular ditch.

In the preceding observations the parapet has been considered as a simple straight line, deriving its defence solely from its own direct fire; but such a condition would most frequently be found inapplicable, in respect of form, in consequence of the natural inequalities of the ground, and unsatisfactory, in respect of defence, in consequence of the imperfect operation of direct fire from the top of a parapet, which can strike the ground in front only in the prolongation of its superior slope, leaving everything within this defenceless; the line in which the superior slope meets the ground is called the "Limiting Line of Defence." A disposition of trace has therefore been adopted by which the fire of one portion of the parapet takes in flank an enemy advancing directly against the adjoining portion; and a work is said to be flanked when the arrangements are such that an enemy cannot advance against any portion of it without being taken in flank by the fire of some other portion. In lines of intrenchments this arrangement leads to a bent line, having angles projecting *towards* the exterior called "salient angles," and angles retired *from* the exterior called "re-entering angles;" and it is evident that in this arrangement the lines AB and AC (fig. 20), which are flanked by BD, CD, in their turn flank BD and CD; such flanking defence is called "reciprocal defence."

Referring back to the subject of defilade, it is evident that a bent line of this kind affords more facility for defilade than a straight line, as it is often possible so to arrange the position of the angles that the salients shall occupy higher ground, while the re-entering angles, though placed lower, shall be compensated for this disadvantage by being further removed from the commanding ground of the enemy.

Though a simple straight line has the disadvantage of depending for its defence solely on direct fire, it is not exposed to be swept along its whole length by an enemy's fire. Fire of this kind is called "enfilade" fire, and is very destructive; it produces the same effect upon the defence as flanking fire upon the attack, viz., it takes the defenders of the line in flank. To guard against this evil, should it be necessary to take up a position in front of ground of a superior command, the long lines AB, AC (fig. 20) should be so directed that their prolongations may fall on low ground at E, F, and not as they would do in the case of AB′, AC′, on the high ground at E′, F′; and, if possible, as where the high ground is not continuous, the prolongations of both short and long lines should fall on low ground between the commanding eminences, an arrangement which will be especially advantageous should the low ground be marshy or otherwise difficult of occupation by an enemy. Such observations as these are only suggestive, since no fixed rules can be laid down to meet all cases. The engineer should examine the ground and adjust his works so as to make the most of its advantages, and to neutralize, as far as possible, its disadvantages.

To determine the height of the parapet by the rules for defilade formulated above, it is necessary to have a correct plan of the ground, and to know the exact levels of the points A, B, C, in every case; but where there is no such plan, the defilading may be effected in practice by levelling poles or boning rods. In this case, the inner boundary of the ground within the parapet to be defiladed being staked out, a boning rod of 7 or 8 feet high, according to the intended normal height of the parapet, should be placed at B on the staked-out line, and another of equal height on the commanding point or ground C (fig. 21), supposed to be at a distance equal to the range of the projectiles from the fire of which the work is to be defiladed. A rod about 12 feet high is then fixed at A, and a cross piece or marker is raised up or down it until it meets the point where the visual line from the top of B to the top of C intersects the pole at A; this operation is simply the mechanical determination of the height obtained in the other method by calculation. If it be required to defilade the whole space between two parallel lines, or that included between the two lines forming the salient angle in fig. 20, it is evident that the work must be defiladed from both sides, and further, that the soldiers standing on the banquette of one line should be secured from the fire of the ground in front of the other, which fire is called *reverse fire*, because it strikes them in rear. This is effected by placing a mound of earth or traverse between them, and determining its height as well as the height of the parapets in the following manner:—

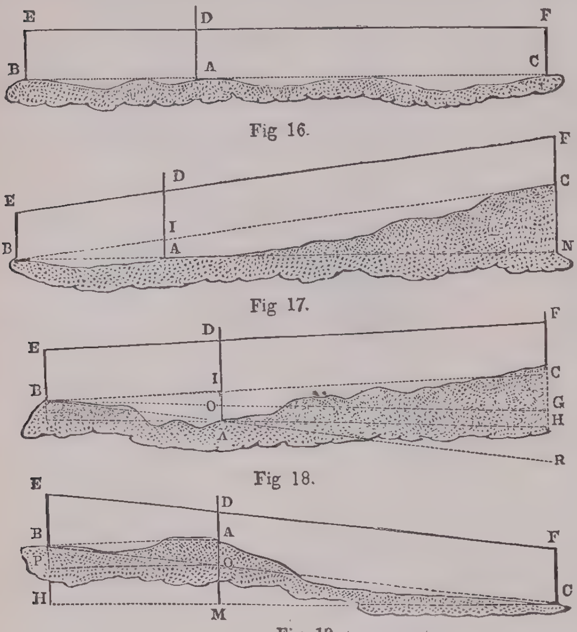

Fig 16.

Fig 17.

Fig 18.

Fig. 19.

Figs. 16–19 illustrate rules for different heights of Parapets.

On the commanding point C (fig. 21) is placed a boning rod CD of the normal height, and another BE of the same height at B, or at the position of the traverse; then the height of the crest of the parapet of A is determined by the intersection of the visual line from D to E with the pole fixed at A, at the point *a*, which is here high, as C is so much higher than A. See preceding rules and equations. In like manner a pole of the proper height being fixed at the extent of range on the opposite side at C′, the visual line from D′ to E determines the height, *a*′, of the parapet of A′, which is much lower than the parapet of A, as A′ and *c*′ are nearly on the same level. Now, to defilade the banquettes, and to determine the height of the traverse necessary for that purpose, set up on the banquette of A a pole *bb* of the same height as CD, C′D′, BE, and the visual line from D′ to *b* determines the height of the traverse at *f*, which is necessary to secure the banquette of A from the reverse fire of C′, whilst the visual line drawn from D to *b*′ determines the height of the traverse sufficient to protect the banquette of A′ from the reverse fire of C.

The application of these principles to a work formed of two lines (or "faces" as they are called), terminating in a salient angle is shown by fig. 22, but the application is the same whether the work is connected with a line of intrenchment as a "redan," is detached as in a "ravelin" and other outworks, or forms part of a peculiar system or arrangement of works, as in the tenaille system of Montalembert, called by its author the angular system,—terms and works which will be hereafter more fully explained. Here the commanding point is supposed to be at M, and to secure the defenders of the face AB from a reverse fire it is necessary to interpose the traverse *cd*, called from its object a "parados. The length of the traverse *cd* is determined by the line MB, beyond which it should project sufficiently to give ample security to a space about 50 feet wide behind the parapet. At the other end, the traverse is not carried up to the salient angle, as it would interfere with the communication, but is completed by *ba*, perpendicular to the other face, by which arrangement the space within the salient and the banquette is left free. The two lines M*d*B and M*cf*, passing through points at the normal height above the banquette, determine the height of the traverse. It may, however, happen that the commands are so situated as to give an enfilade fire along both the faces AB, AB′ (fig. 23). In this case a small work DAD′ is formed in connection with the parapet, by drawing lines parallel to the crests CB and C′B′ at a distance from them equal to the breadth of the banquette, and then determining, in the manner explained, the heights at A necessary to defilade a certain length of the banquettes of CB and C′B′ from the fire sweeping them, and assuming the greater of the two as the height of the parapet at A. This work is called a bonnette; and when the height necessary to defilade the whole of one or both faces is found to exceed 12 feet, the height of A should be restricted to that limit, and traverses T, T′, T² should be placed at such distances as shall defilade the remainder of the work.

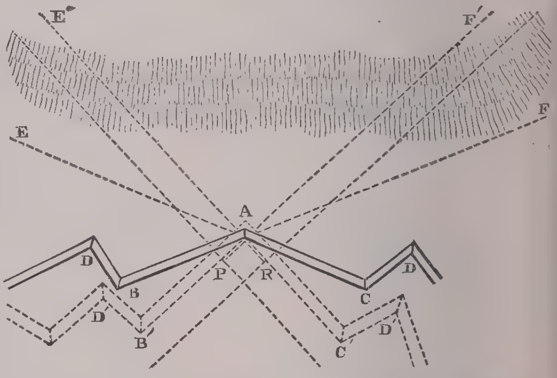

Fig. 20.—Illustrating defence against Enfilade Fire.

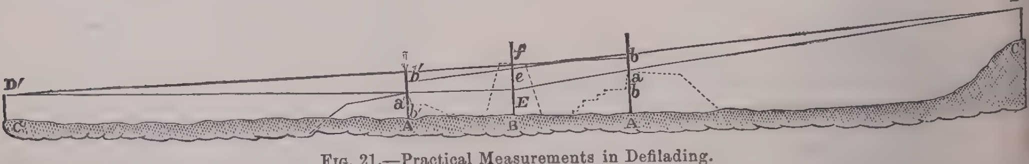

Fig. 21.—Practical Measurements in Defilading.

The internal space may frequently be sufficiently defiladed by raising the salient portion of the parapet without disturbing the line of direction of the crest; but in that case the banquettes of the two faces would not be covered from enfilade fire, and hence the necessity of a bonnette. The increased height of the parapet of the bonnette renders it necessary to adopt two banquettes *b*, *b*′, one below the other, and each provided with steps to facilitate ascent (figs. 23, 24). The operation of defilading may be also effected by *planes* of defilade; as, for example, if the line which marks out or limits the space to be defiladed be first drawn, and a plane be supposed to pass through a line either 6 ft. 6 in. or 8 ft.

(or whatever height between these may be assumed as the normal height N) above the limiting line, and through a point the same height above the commanding point, this plane will determine the height of the parapet, the crest of which will necessarily be in it.

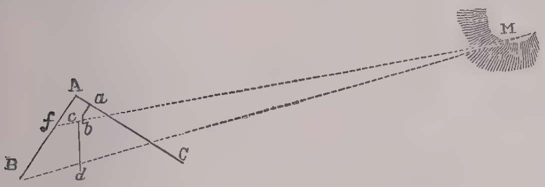

Fig. 22.

Where the parapet is continued not only on the flanks but also in rear, so as to form an inclosed work, it may often be necessary to defilade it in various directions as in fig. 25. Where two traverses or parados cross each other, they must, of course, be so placed that they shall not only completely defilade the whole interior space of the work, but shall secure from reverse fire the banquette on each side, the normal N being therefore at least 6 ft. 6 in. above the banquette. Where traverses of this kind become necessary, the engineer must take into account the space they will occupy, and plan his work accordingly; and should he be able to render the difficulty of attacking one side of his works very great, he may construct the traverses so that they may be used as retrenchments, and thus increase the means of defence; for example, S being the salient of greatest strength, *bcb* might be defended, and then *bcd*.

This subject has been enlarged upon because it is of much importance in military engineering, as the safety of a long line of works may be endangered by defective defilade. Though considered here in a practical form, it depends entirely upon geometrical principles, and instruction in descriptive geometry is therefore essential in all schools of military engineering.

Having determined the relief of the crest of the parapet in reference to the plane of site, all the other vertical dimensions follow from it, as shown in several of the preceding figures; whilst the horizontal dimensions are determined by the thickness necessary to resist the enemy's missiles and by the slopes required to ensure stability. The Penetration at a mean range into common earth after it has been dug up and well-rammed and into other materials is as stated below, and to these dimensions one half should be added for the thickness for security.

English Field Artillery.

Field Guns. M.L.R.		Penetration at 1000 yards with common shell.						Remarks.

Martini-Henry.	480 grs.	14	5	0·5	0·25	0·13

The penetration into sand is about two-thirds the penetration into earth, and about one-half that into clay.

The penetration into oak is about half that into fir.

With light, sandy, or gravelly soil, or, when ramming can only be imperfectly performed, greater thickness should be allowed; and as a wide and deep ditch must always materially strengthen the work before which it is placed, there can be no reason other than want of time, want of men, or difficulty of ground, for reducing the thickness of the parapet below 14, or at the utmost 12 feet. For forming the parapet under peculiar circumstances of difficulty the engineer will avail himself of every fitting substance which may be at hand, such as bags of wool, mattresses, fire-wood, manure heaps, and fascines, either by themselves or packed in gabions. The resistance of fascines is not great, their strength being rapidly diminished by the speedy fracture of their branches when exposed to sharp fire.

With these data it will be easy to regulate all the dimensions of the parapet,—the height of its crest, or the relief of the work, having been first established. Thus the banquette or step on which the men stand, when firing over the parapet, should for convenience be 4 ft. 3 in. below the crest. The breadth or tread should for a single rank be 3 ft., for a double rank 5 ft.; the surface should slope backwards 2 inches in the 3 ft., 3 inches in the 5 ft., so as to discharge water freely and keep the banquette dry; the base of the interior slope of the banquette up which the men mount should be twice its height; if the height of the parapet exceed the normal height, the banquette should have two treads or steps, the lower about seven feet below the crest, so that one rank of men may stand thereon whilst reloading the muskets of the rank on the step above them; or it should have three steps, each with a rise of 1 ft., and a tread of 1 ft., or 1 ft. 3 in., sloping slightly to the rear, by which arrangement the necessary excavation of the ditch will be diminished, and less of the interior space occupied. The interior slope of the parapet should be made very steep, so that a man firing over the parapet should be as close to it as possible; the base should not exceed one half the height; the superior slope, or "*plongée*," of the parapet, by which the fire is directed towards the point on which it is to act, should not be less than one-ninth, nor more than one-fourth of its thickness, and in service is generally made one-sixth; but as the increase of the slope facilitates the destruction of the crest, it should be kept as slight as possible. It is usual on the Continent to retain the angle of the crest, as a constant quantity, at 100°, and to increase the base of the interior slope as the plunge increases, and *vice versâ;* but this is not satisfactory, since, the height of the soldier's shoulder remaining constant whilst the line of plunge varies, the fire will not be always in the true direction; and it is preferable to keep the base of the interior slope as small as possible, and to make the top of the parapet at the crest horizontal for one or two feet commencing the plunge therefrom, but reducing the top as the plunge increases. This flat top will facilitate the use of sand bags (bags filled with earth), which are sometimes so arranged on the crest of the parapet as to form loopholes for the musketry, thereby adding to the cover of the men. The base of the exterior slope of the parapet should at least equal its height, though possibly in some soils—*e.g.*, chalk—the exterior slope may stand at a steeper angle than 45°. The slopes of the escarp and counterscarp should be as steep as practicable, but generally they will be the same as the exterior slope. Between the exterior slope and the escarp a "berm" is left. This berm is a space at least 1 ft. 6 in, wide and slightly inclined downwards and outwards for drainage; it

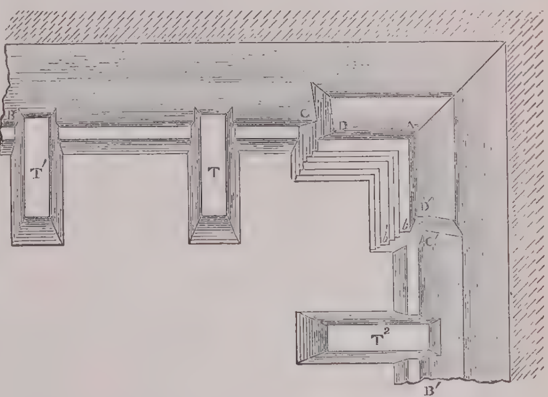

Fig. 23, showing Bonnette DAD′, and Traverses T, T′ T².

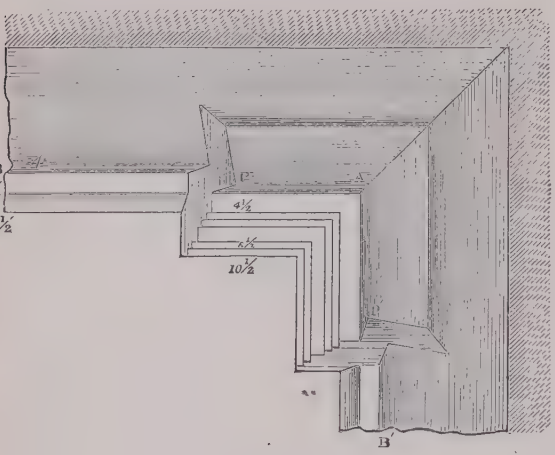

FIG. 24.

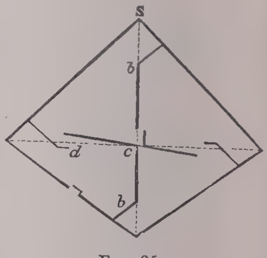

FIG. 25.

gives greater stability to the exterior slope and to the escarp, prevents the earth from the exterior slope from falling into the ditch, and is a standing ground for the repair of the parapet. Where steeper slopes are indispensable, the earth must be retained in place by a wall called a "revetment," which may be formed of fascines (long cylindrical fagots), hurdles, sods, planks, clay puddling, and, in the interior of works, of sand bags. The base of the interior slope of the glacis should be equal to its height, and the exterior slope should have a slope of 1 in 12. The command of the crest of the parapet over that of the glacis should be such that an assailant, standing on the crest of the latter, should not be able to fire into the interior of the work,—a condition which requires a command over the glacis of 5½ feet, so that with a parapet 7 feet high the *maximum* height of glacis would be 1½ feet. The minimum height of the glacis is determined by another condition, viz., that the fire from the parapet should pass at no greater distance than 2 feet above its surface; and in no case should the plunge or slope of the glacis be greater than that of the parapet. An advanced glacis is sometimes adopted either to render the cover more effectual, or to occupy a favorable line for first opposing the progress of the enemy. Fig. 26 shows this arrangement, gg^1, being the first or ordinary glacis, and g^2g^3 the second or advanced glacis. The slope of these glacis should not be such as to withdraw the assailants from the grazing fire of the parapet, and if it be not possible to extend the slope of g^2g^3 so far as to keep it in the prolongation of the line cg^2, it should be so arranged that no point of the slope should be more than 2 feet below that line or the plane corresponding to it, namely, the plane passing through the crest of the parapet and the crest of the advanced glacis. To form the advanced glacis, the slope at g is prolonged below the surface of the ground to g^1, the earth excavated in doing this supplying the material for the glacis. When it is intended that the defence of this advanced glacis shall be derived solely from the parapet, either an abattis or rows of stakes may be placed immediately behind it, so as to stop the advance of the enemy when at the point of maximum exposure, but advanced glacis may often assume the character of successive intrenchments, and be defended with vigor and success. This figure will be again referred to when treating on defence by mines. The height of the parapet being determined by the amount of cover required, and the thickness by the nature of the projectile to which it is exposed, the whole profile or section is necessarily completed on the principles pointed out, and the bulk therefore of earth contained in any portion of the parapet will be equal to the area of the mean or average profile multiplied by the length of that portion. Now, as this earth must be obtained from the ditch, the dimensions of the latter depend on those of the former; and the volume of any portion of the excavated ditch will also be equal to the mean section of that portion multiplied by its length.

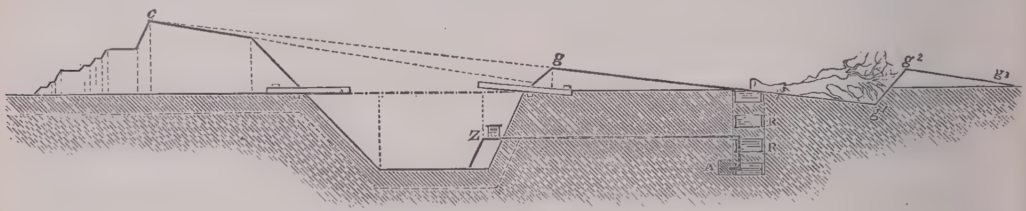

FIG. 26.

If, therefore, P represent the area of the mean section of this portion of the parapet, D the area of the mean section of the corresponding portion of the ditch, and L the length of this portion, then LP = LD, provided the earth be of the same bulk after as before excavation; but this is not the case, for after having been broken up from its previously closely packed condition, it is found that the "remblai" or earth built up exceeds the "deblai" or earth excavated by a coefficient varying with the nature of the soil, being in sandy soil nearly 0. Thus if $\frac{1}{m}$ represent the coefficient, in sand it is 0, in earth of medium tenacity $\frac{1}{12}$, and in very strong and naturally compressed earth $\frac{1}{6}$; so that to render the earth of the ditch just equal to that of the parapet, the above equation should be $LP = L\left(D + \frac{1}{m}D\right)$ and $P = D + \frac{1}{m}D$, or $D = \frac{m}{m+1}P$. As, however, the earth resulting from this excess, even allowing for the greater length of the ditch in polygonal works, will be required for forming the glacis, or for making up the banks, called "barbettes," in the salients constructed for raising guns sufficiently high to fire over the parapet, the dimensions of the ditch may be safely estimated without reference to the excess, as follows:—

Let x be the breadth of the bottom of the ditch, and y its depth; and let the sum of the bases of the slopes of the escarp and counterscarp be represented as a function of the depth by the fraction $\frac{r}{s}y$; then $x + \frac{r}{s}y$ will be equal to the breadth of the ditch at top, and $D = \frac{y}{2}\left(x + x + \frac{r}{s}y\right)$; whence $x = \frac{D}{y} - \frac{r}{2s}y$, and $y = \frac{s}{r}\left(-x + \sqrt{x^2 + \frac{2r}{s}D}\right)$. Now, as the defensive object of the ditch requires that it should be both deep and wide enough to form a decided obstacle to an enemy, the width ought not to be less than 18 feet, whilst the depth should have no other limit than that arising from the difficulty of raising the earth, which fixes 12 feet as about the maximum. Taking $y = 12$ feet, $\frac{r}{s} = \frac{3}{2}$, and $D = 108$ square feet, then $x = 9 - 9 = 0$, and the width of the ditch therefore $= \frac{3}{2}$ of $12 = 18$ feet,—the ditch being triangular.

Assuming a profile area of 70, corresponding to a parapet 7 feet high and only 6 feet thick, and making $x = 0$ for a triangular ditch, $y = \sqrt{\frac{2s}{r}D} = 9$ ft. 7 in., and the width of the ditch $= 14\frac{1}{2}$ feet; with a profile area of 116 feet corresponding to a parapet 7½ feet high and 12 feet thick, the depth of the ditch, if triangular, is 12½ feet, and the width 18¾ feet; so that this profile appears about the maximum for a triangular ditch with a profile area of 163 feet, corresponding to a parapet 8 feet high and 18 feet thick. With a banquette 4½ feet wide a triangular ditch would give $y = 14\frac{3}{4}$ feet, so that such a form would be inconvenient; but taking $x = 4$ feet as the width of the bottom of the ditch, y or the depth becomes 12 ft. 4 in., and the width of the top of the ditch 22½ feet—a very well-proportioned ditch.

In the preceding cases the base of the slope of the escarp has been assumed as equal to its height, and that of the slope of the counterscarp as equal to half its height. Should the nature of the soil be such as to require the base to be equal to the height in both escarp and counterscarp, $\frac{r}{s}y = 2y$; and should the soil be sufficiently firm to admit of a base of one-half in both, $\frac{r}{s}y = y$. In the first of these cases, even with the large profile area last named, the ditch may be made triangular with a depth of 12½ feet, and a breadth of 25 feet; and in the second a triangular ditch is inadmissible with a profile area of 116 feet, as the depth would be more than 15 feet; indeed it would be inadmissible with profile areas beyond 85 square feet, for which a depth of 13 feet would be required. Before leaving this subject, a few words may be said respecting the "berm." The most effectual escarp for defence is that which forms one continuous plane with the exterior slope, or at least which commences immediately where the other ends, as the absolute relief of the parapet is then a maximum, and there is no berm; but in many cases it would be imprudent to carry the parapet to the edge of the escarp, as injury to the latter would occasion the fall of part of the parapet, while the difficulty of construction would be greatly increased by having no intermediate stage between the bottom of the ditch and the top of the parapet. The "berm," or step between the top of the escarp and the bottom of the parapet, is made from 1 foot 6 inches to 4 feet wide, according to the nature of the soil, and it then becomes possible in some cases to increase the slope of the escarp to a base of one-half or two-thirds, or at least to such a slope as shall place the foot of the escarp in the prolongation of the exterior slope of the parapet. The berm is encumbered with obstacles to prevent an enemy from making use of it as a halting-place (see fig. 14). The slope of the counterscarp is usually one-third, one-half, or two-thirds, when that of the escarp is one-half, two-thirds, or 1; the bottom of the ditch should slope from the sides to the centre, to carry off the water, and obstacles should be provided there to prevent the enemy from collecting and reforming his men in the ditch, which, in all cases of simple lines, without flanking defences, he would do were it left free from obstructions.

FIELD FORTIFICATION.

The parapet has been hitherto considered principally in its character as the simplest element of defence, affording at once protection to the soldiers behind it and obstructing the advance of their enemies; but it is now time to consider the manner in which this parapet may be so arranged as to constitute a series of defensive and mutually defending works. If the antiquity of an invention be estimated by its position in the social history of the races of mankind, there can be no doubt that earthworks claim the priority over other forms of defence. In North America vestiges of circular earthen entrenchments, as well as of works of other forms, have been discovered, the antiquity of which is unknown; and in more recent times small parties of the aboriginal inhabitants encountering greater numbers of a hostile tribe have been known to excavate hollow spaces in the ground, and, throwing out the earth, to form around them circular entrenchments in which they have defended themselves to the last. In Ireland the ancient inhabitants have left similar relics of their earthen defences; in Great Britain there are numerous similar remains, the works of the Romans and of people long antecedent to the Romans; but the consideration of earthen works for the defence of extensive positions will be resumed further on, and such works will be considered here only in connection with the arrangements adopted by an army in the field for its own immediate security.

The art of constructing temporary works in the field for this purpose is called Field Fortification. This art is of very high antiquity; the Roman soldiers relied much upon such works, and executed them with wonderful rapidity, even in the presence of an enemy.

Shelter Trenches.—Of this art the simplest form is that in which troops are preserved intact until the moment of attack arrives. At first sight it would seem that this can best be effected by keeping them out of fire. The increase in the range of arms of all kinds has, however, become so great that it is no longer possible to keep troops out of fire and yet in a sufficiently advanced position from which they shall be able to attack promptly; hence it has become an absolute necessity to provide shelter for them.

A very shallow trench with the earth thrown to the front will afford to men lying in it cover against artillery fire, and a good rest for their arms when they have occasion to deliver their own fire. Moreover, it presents no obstacle to the advance of supporting troops, and offers but little mark to the enemy. Such trenches (figs. 27, 28, 29, 30) are called shelter trenches, and may be made of any depth or form according to the time and means available. They are very difficult of capture by the front attack, when defended by trained troops with breech-loading rifled arms, and can be quickly developed into regular intrenchments. The ordinary forms of shelter trench in use in the British army are shown in figs. 28, 29, and 30.

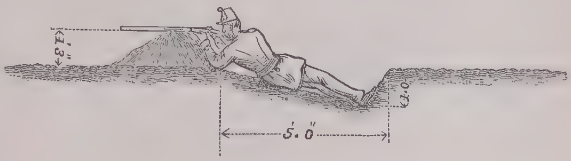

FIG. 27.—Shelter Trench,—constructed in 25 min. to ½-hour.

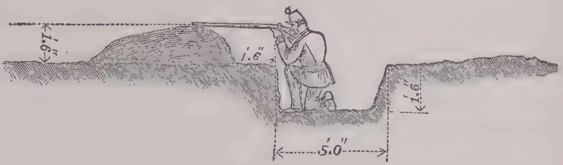

FIG. 28.—Shelter Trench,—1 hour.

The Russians made use of shelter trenches with great effect in the defence of Sebastopol, and since that siege their employment has steadily developed.

In more recent times the greatest use of hasty entrenchments, though perhaps in the form rather of a line of intrenchments than of shelter trenches, was made by the Americans in the war of secession. Wherever they halted, no matter how short the time at their disposal, they threw up shelter. Each man worked for himself, and as if by instinct, and before fires were lit or provisions cooked, an intrenchment of some kind was formed. Probably the Americans had acquired this habit in their campaigns against the neighboring Indians; and no doubt the superiority of rifled small arms, then for the first time freely used, thoroughly imbued them with a sense of the value of the slightest protection. General Sherman's campaign in Atlanta, and the actions in the neighborhood of Richmond and Petersburg, furnish numerous instances. With reference to them General Barnard reports that a simple trench defended by two ranks of foot soldiers is an obstacle unassailable by direct attack. General Wright relates that, attacking a handful of infantry, in single rank, behind a parapet and trench, with two divisions in line, the number of his casualties exceeded the number of the enemy, and

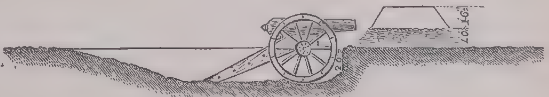

FIG. 29.—Shelter Trench,—1 hour.

that if the intrenchment had been defended by two ranks of good troops, a whole army corps could not have taken it. And in summing up his relation, he says that a simple trench, defended by two ranks of foot soldiers, covered by abattis and other obstacles placed so that the new rifled arms have full scope, is absolutely impregnable except by surprise.

After the fall of Nicopolis in August, 1877, 28 battalions of Turks, numbering about 10,000 men, collected at Plevna, and at once commenced to form shelter trenches; they were very deficient in artillery. Krudener attacked them four days after with 7000 Russians and 30 guns, and was defeated with a loss of 2800 men. Ten days later he again attacked with 30,000 men and 170 guns, but in the mean time the Turks had thrown up several redoubts, and had so extended their shelter trenches that their position was beginning to assume the condition of an intrenched camp; moreover, their strength had been swelled by reinforcements to 45,000 men. The Russians were again defeated with a loss of 8000 men. Six weeks later, upon the 30th September, Krudener, who had received 30 siege guns, having shelled the Turkish position for four days previously, attacked a third time with 50,000 Russians and Roumanians; but the Turks had in the interval received reinforcements of 10,000 men, and he was a third time repulsed with a loss of 15,000 men, though the Roumanians obtained possession of and held a large redoubt called Gravitza. It then became evident to the Russians that Plevna could not be taken by assault, and they commenced to besiege by rule. By the 24th of October they had completed the investment by the occupation of the Loftcha and Rahova roads, all of which were previously open to the Turks, and had brought into battery against it 300 guns, 40 of which were siege guns. By the 10th of December they had collected 110,000 men and 500 guns around Plevna; and shortly after, Osman Pacha, having been repulsed with a loss of 6800 men in an attempt to cut his way out, surrendered, and his whole force, amounting to 43,000 men and 70 guns, became prisoners of war.

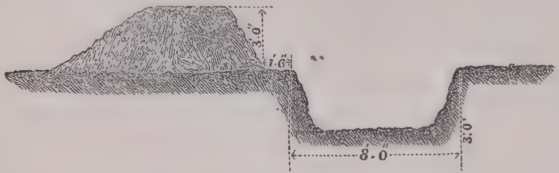

FIG. 30.—Shelter Trench,—3½ hours.

An army intrenched or fortified in the field is in many respects of the same effect as a fortress; the intrenchments supply the lack of numbers, and enable it to cover a country, to stop the advance of a superior enemy, or, if he chooses to risk a battle, oblige him to engage at a disadvantage. Charles V. furnishes a notable instance of the first. Opposed to a combined force of twice his strength, he at once commenced to intrench his army. In a few hours he was in a position to resist attack; in ten days he was so secure that, upon receiving reinforcements a few days later, he was enabled to assume an offensive which led in four months to the termimation of the campaign in his favor. "In a war of march and manœuvre," says Napoleon, "if you would avoid a battle with a superior army, it is necessary to intrench every night, and to occupy a good defensive position. The natural positions which are ordinarily met with are not sufficient to protect an army against superior numbers without recourse to art. Those who proscribe lines of circumvallation, and the assistance which the science of the engineer can afford, deprive themselves gratuitously of an auxiliary which is never injurious, always useful, and often indispensable."[1]

Whenever Napoleon had time and occasion for strengthening his position by field-works, he acted upon the principles recommended in the above extract, as almost all his predecessors had done. In the wars which followed the Revolution of 1688, in those of Queen Anne's reign, and during the Seven Years' War, we find the commanders of each period, William III., the duke of Marlborough, Marshal Villars, Marshal Saxe, Frederick II., and Marshal Daun, practically exemplifying their conviction of the great utility of field-works. Seven redoubts thrown up overnight saved Peter the Great at Pultowa, and enabled him to gain a decisive victory over his formidable antagonist; and at Borodino, three redoubts and eight flêches thrown up hastily by the Russians, caused the French great loss, and rendered the victory, which they gained by incredible efforts of gallantry, fatally costly; and it is not improbable that if the main redoubt had been closed at its gorge the French would have failed to take it. In 1761 Frederick the Great, having only 55,000 men to oppose to the united Austrian and Russian forces of 130,000 men, intrenched himself in the strong position of Bunzelwitz, in Upper Silesia, not far from Schweidnitz, which he held until the united armies were forced to retire for want of supplies. It has been argued by some that intrenchments and field-works have oftener been carried than successfully defended, and that hence incommensurate importance has been attached to them. But it should be remembered that victory in such circumstances has been purchased at an expense which has often rendered it in effect equivalent to defeat, and that a practice which the greatest commanders of ancient and modern times have approved and followed cannot be of doubtful utility. At Austerlitz, where the contending armies were nearly equal, Napoleon was preparing to superintend the construction of intrenchments when he found himself called upon to receive battle; and in Portugal, the duke of Wellington showed to what account the art of the engineer might be turned for influencing, not merely the fortune of a campaign, but the fate of a cause. The lines of Torres Vedras, which the powerful French army under Masséna was unable to pass, and from which the wave of war was rolled back broken into Spain, were perhaps the most remarkable works of the kind ever constructed.

"Lisbon," says Sir John Jones, "being situated at the extremity of a peninsula formed by the sea and the Tagus, it is plain that if an army be posted across the peninsula, no enemy can penetrate into the city without a direct attack on the army so posted. It was on this principle that the lines covering Lisbon were planned by Lord Wellington. Nature drew the rude outline of a strong defensive position, and art rendered it perfect. A tract of country thirty miles in extent from the mouth of the Zizandra on the ocean to Alhandra on the Tagus, was modelled into a field of battle; mountains were scarped perpendicularly, rivers dammed, and inundations formed; all roads favorable to the enemy were destroyed, and others made to facilitate the communications of the defenders; formidable works were erected to strengthen and support the weak parts, whilst numerous cannon, placed on inaccessible points, commanded the approaches and gave an equality of defence to the whole position."[2] These lines were not continuous and connected works; they consisted of independent forts, redoubts, flêches, redans, batteries, so placed as to command and enfilade every approach, and to support each other by a cross and flanking fire. The first line occupied a front of twenty-nine miles between the sea and the Tagus, and by means of telegraphs intelligence could be conveyed from one extremity to the other in a few minutes; whilst the troops, disposed in masses in the rear of the works, were ready to move upon any point of attack by interior communications shorter than any by which the enemy could advance. "The aim and scope of these works," says Colonel Napier, "was to bar the passes, and to strengthen the fighting positions between them, without impeding the movements of the army. These objects were attained; and the loss of the first line would not have been injurious, save in reputation, because the retreat was secure upon the second and stronger line, and the guns of the first were all of inferior calibre mounted on common truck carriages, and consequently, immovable and useless to the enemy."[3] The two lines covered an extent of fifty miles, on which were erected one hundred and fifty forts, mounting in all about six hundred pieces of artillery.

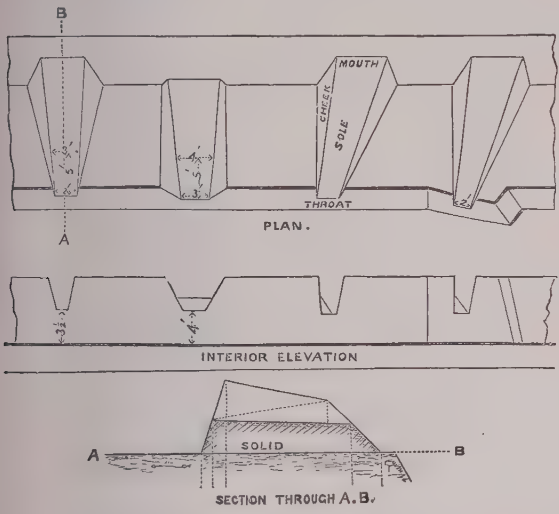
---

[1] *Military Maxims of Napoleon.*

[2] *War in Spain*, p. 124. The French army which invaded Portugal under Masséna consisted of three corps, under Marshals Ney and Junot and General Regnier, amounting in all to 66,000 infantry and 6000 cavalry, besides a strong body of the imperial guard, which crossed the Pyrenees after the invading force had commenced its march from the neighborhood of Salamanca. The force collected to oppose this threatened invasion did not exceed 48,000 infantry and 3000 cavalry, of which about half were Portuguese levies, yet untried in any general action, and of which a very unfavorable opinion still continued to be entertained. In point of numbers, and still more in the composition of their army, therefore, the French had a decided superiority; but all their advantages were neutralized by the defensive position of Torres Vedras.

[3] *History of the War in the Peninsula*, vol. iii.

Before this formidable position, defended by a double line of works, and by an army massed and ready to move upon any point by interior communications, the French remained five months, wasting their numbers and resources; until at length, finding it utterly impracticable to force any part of even the first line, they were obliged to retire from Portugal, closely followed and harassed by the army which they had previously driven out of Spain. Yet perfect as were the lines of Torres Vedras, and though one of the ablest of the French generals and a veteran French army were foiled before them, it is not meant to infer that the system of separate field-works is a model to be followed on all occasions; for, though the old method of covering a considerable front by a continued line of regular bastions and curtains has been generally condemned by modern engineers, there may be situations where the application of continued lines may be judiciously made. There is no fixed rule; the nature of the ground and of the position to be defended must determine the proper description of works.



PLAN.

INTERIOR ELEVATION

SECTION THROUGH A.B.

Fig. 31.—Embrasures.

But as in defence artillery should be combined with musketry, it is necessary that in the arrangement of lines provision should be made for the use of cannon; and as they should be preserved for action at the right moment, they should, when practicable, be mounted on carriages of such a height as will enable them to give their fire over a full parapet, the gun and carriage disappearing below the parapet after the fire is given, so that the loading may be effected in security. In particular cases, such as in flanks where the lateral range of the guns is restricted, and where the guns are not exposed, or are exposed to indirect fire only, openings in the parapet called "Embrasures" may be made use of, but they have many serious disadvantages:—they weaken the parapets; they offer distinct marks to the enemy; they are easily blown down by shells; they are destroyed by the fire of their own guns; they are difficult to construct, and still more difficult to maintain. The interior opening called the "Throat" of the embrasure is made wide enough to admit the muzzle of the gun, about 20 inches; the width of the outer opening called the "Mouth" is determined by the lateral range of the gun, which should not exceed 20°. The slope of the bottom of the embrasure, called the "Sole," is determined by the object upon which the fire of the gun is to be directed. When required for indirect fire only, the sole is made countersloping; by this arrangement the exposure of the gun detachment is considerably lessened, and, in order to diminish still further this exposure, the sides of the embrasures are made with a winding slope,—steep at the throat, from 6 to 1 or less, and flattening out at the mouth to 1 to 1. As a rule, embrasures should not be made till they are required, so that the parapet may be made solid in the first instance (see fig. 31).

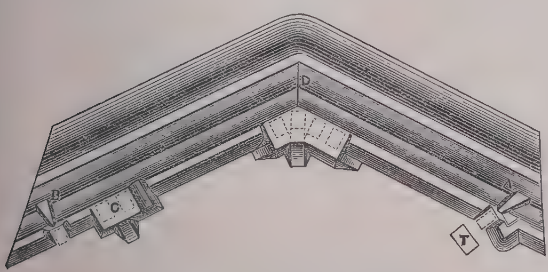


Fig. 32.—Embrasures and Barbettes.

The portion of parapet below the embrasure is called Genouillère (from *genou*, the knee), and should be 2 feet 5 inches high; the portion between two embrasures is called a Merlon, from the Italian *merlone*, a battlement; the bottom of the embrasure is called its Sole; and, as has been suggested in respect to the superior slope of the parapet, it may be horizontal for the first two feet from the neck, and then slope downwards as much as may be necessary for the depression required in firing. The direction of the embrasure depends on the direction of the line of fire; it may be either perpendicular to the crest or oblique. In the latter case, should the obliquity be very great, or exceeding 70°, the crest of the parapet must be made re-entering, so as to strengthen it near the neck, and to enable the gun-carriage to be brought up square to the parapet. The sides of the embrasure are called Cheeks, and should be revetted with sods, fascines, gabions (cylindrical baskets made of wicker, and filled with earth after they are in position), sandbags, planks, or hurdles. In fig. 32, on the left, at B, a direct embrasure is seen cut straight through the parapet; and on the right at A, an oblique one, both being intended to enfilade the ditches opposite them; and it will be observed that, from the obliquity of the right-hand embrasure, the interior of the work becomes so much exposed, that a traverse, T, behind the embrasure, becomes necessary. Barbettes are also shown in this figure—one at the salient at D for four guns, and another at C, perpendicular to the face, for two. The terreplein of the Barbette should be $3\frac{1}{2}$ feet below the crest of the parapet; its length from front to rear from 18 feet to 20 feet; and its breadth, for a single gun, from 15 feet to 18 feet, according as it may be necessary to fire more or less obliquely; a breadth of 15 feet should be added for each additional gun. To add to the lateral sweep or range of the gun, without diminishing the banquette, or, in other words, the musketry fire, the barbette may be made wider in the rear than in front. In proportion to its magnitude should be the number of "*Ramps*," or slopes of approach; as, for example, at C only one, at D three. The ramps should be from 8 to 9 feet wide, and their slopes should have bases equal to 4 times the heigh of the barbette. The lateral slopes of the barbette and of its ramps should be revetted whenever it is

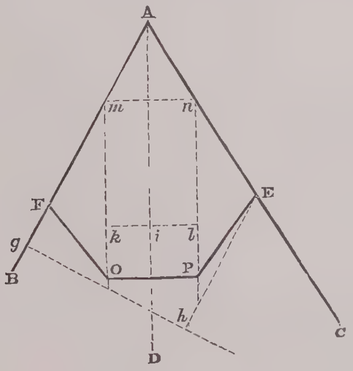

Fig. 33.—Construction of a Barbette in a Salient.

possible to obtain sods, fascines, hurdles, or other materials suited for the purpose, in order to economize space in the work, as the base of the slope may be then reduced to one-fourth or one-sixth the height; when unrevetted they have slopes of one-sixth. The terreplein of the barbette may require, as at C, to be covered in flank by a traverse. The mode of constructing a barbette in a salient is exhibited in fig. 33.

At any point *g* of the face AB raise a perpendicular *gh*, either 18 or 20 feet in length, to include the amount of recoil; at the point *h* thus determined raise a perpendicular to *gh*, and prolong it to its intersection with the other face AC at E, then setting off AF on the other face equal to AE. On the capital AD set off a double perpendicular at any point *i*, prolonging it both ways, and making *ik* and *il* each at least equal to 4½ feet to represent the half breadth of the platform on which the gun-carriage is intended to stand and move; through the points *k* and *l* draw parallels to the capital, cutting the faces on the points *m* and *n*; join *m*, *n*, and parallel to the line *mn* draw the line OP at 18 or 20 feet distant from it, when *mn*PO forms the platform. Join FO and EP, and AEPOF will represent the contour or trace of the barbette. The manner in which the crest of the parapet is formed above the salient A, and the mode in which the firing may be effected in directions perpendicular to the faces, as well as in the direction of the capital, are shown in fig. 34.

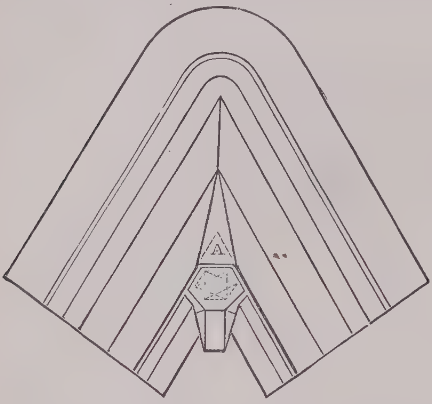

Fig. 34.

In the case of a partly sunken parapet, in which the portion above the banquette is raised above and the portion below the banquette excavated below the plane of site,—as in fig. 35, the barbette constructed in the hollow portion will enable the gun to fire over the parapet; and it should be protected by forming a bonnetted embrasure, which may be sometimes made large enough, as here represented, to hold two guns. It need scarcely be added that an engineer ought to be ready to adapt any of the expedients here briefly noticed to the circumstances of the case before him, and that a mind stored with resources against any contingency is the highest endowment of a good officer. It must be obvious that in Field Fortification even a limited knowledge of the art of war opens a wide field for the exercise of the talents and resources of engineers; but the possession of a military coup-d'œil, which comprehends at a glance the true bearing or character of objects and events is necessary for the conversion of stores of information to the best practical uses. In passing through a country, it requires an experienced eye to seize quickly on whatever it presents calculated to prove advantageous or disadvantageous for attack or defence; to appreciate the value of villages, inclosures, and broken ground; to know where to dam up rivers, to scarp heights, to form abattis, trous-de-loup, and other obstacles; to select the best situations for field-forts and redoubts, and the best sites for batteries; and to arrange the defensive measures with reference to the number of troops disposable, so that the movements of the defenders may not be obstructed or retarded, and their communications may be short and easy. The variety of ground upon which military operations must be carried on precludes the possibility of laying down fixed rules in regard to this subject; the accidents of the ground, and the peculiar circumstances of each individual case, must determine the extent and description of the works to be constructed, as well as the obstacles most proper to be formed for retarding the advance of an enemy.[1]

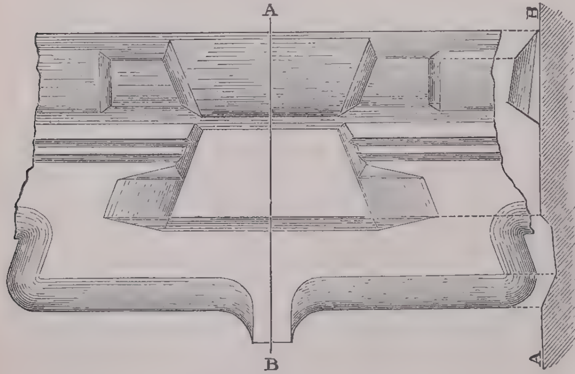

Fig. 35.

But though the observance of fixed rules be impracticable, general principles are of universal application; and certain maxims founded upon them hold good in the construction of field-works as much as in the erection of the complicated works of a fortress. These maxims, which are of invariable application, are—(1) that the works to be flanked must never be beyond the range of the projectiles used in the works flanking them, or, in other words, that the length of the lines of defence must never exceed the effective range of the weapons in use; (2) that the angles of defence must be about right angles; (3) that the salient angles of all works must be as obtuse as possible; (4) that the ditches must be efficiently flanked; (5) that the relief of the flanking works must be determined by the length of the lines of defence; and (6) that the works must be constructed with reference not only to the direct and immediate obstacles which they present to the enemy, and to the positive effect of their fire on the approaches to them, but also to the support they derive from or afford to other works.

---

[1] Shaw's *Course of Field Fortification*, p. 9 *seq.* Much assistance has been derived from this useful work in the compilation of this article, as well as from the admirable treatise on *Field Fortification*, by Fischmeister, translated by Rieffel into French, the figures of which have been freely used.

The first class are of the simplest kind of field-works, and serve as cover in front of avenues, bridges (see fig. 49), causeways, and the like; being open at the gorge, they are only used when their extremities rest on rivers, or on obstacles which prevent their being turned, or when within the full sweeping fire of works in their rear. To increase the strength of a "Redan" its faces are sometimes broken into a kind of flank, as in fig. 36. In the "Double Redan," or "queue d'hironde," fig. 37, the re-entering faces defend each other. "Tenailled Heads" (fig. 38) are used in situations which require a greater extent of front. "Bastioned Heads" (fig. 39) are also employed in similar circumstances.

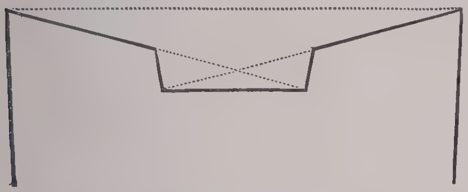

FIG. 39.—Bastioned Heads.

"Redoubts" (fig. 40) are closed works of square or polygonal figure. In square redoubts provision should be made for defending the ground before the angles, which, however, are sometimes rounded or cut *en crémaillère*, so that a direct fire may be delivered from them.

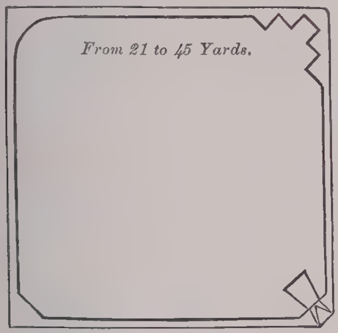

FIG. 40.—Redoubts.

Half-closed Redoubts, that is redoubts in which the gorges are closed by thin parapets or timber stockades, may more fitly be classed here. They are employed when it is intended that their interior shall be open to artillery fire, so that an enemy having captured may not be able either to retain them or to convert them to his own uses.

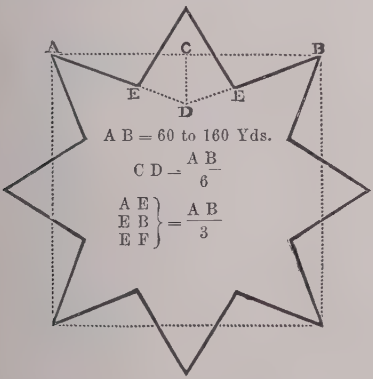

FIG. 41.—Star-Forts.

Forts are works the parapets of which defend the ditches, and this distinguishes them from redoubts, the parapets of which do not.

"Star-Forts" (fig. 41) are designed to deliver a cross fire from the adjacent sides; but according to Jomini, they are the very worst description of fortification; they cannot have flanks, and the re-entering angles take so much from the interior space that it is impossible to place troops and artillery in them sufficient for their defence, an opinion confirmed by the practice of Sir Richard Fletcher and Sir John Jones in the construction of the lines of Torres Vedras, where the trace of the redoubts was varied to suit the conformation of the ground.

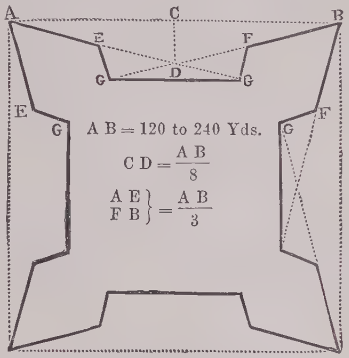

FIG. 42.—Bastioned Forts.

In "Bastioned Forts," fig. 42, the flanking defence afforded by the parapets to the ditches is nearly perfect. As bastioned forts are only constructed in special cases of importance, no labor or expense should be spared in their formation. The bastioned face may be applied to any polygon provided that its angles are not less than 90°. When the angles are less than 90° the salients of the bastions are too acute.

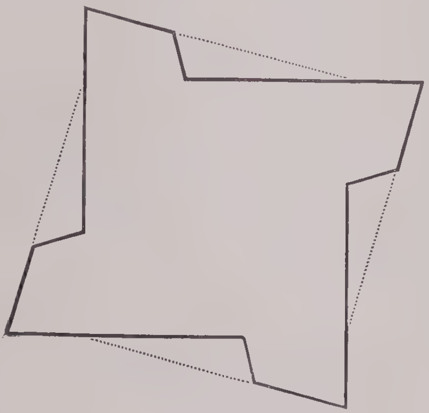

FIG. 43.—Demi-bastioned Forts.

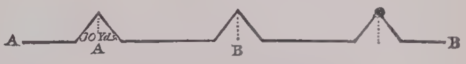
"Demi-bastioned Forts" (fig. 43) inclose a greater interior space than Bastioned Forts, but a portion of their ditches are only defended by an oblique fire from the parapets of their faces.

The parapets of all these works should be of sufficient thickness to resist the fire of the heaviest guns that can be brought against them. In some cases it will be necessary that the parapets should be strong enough to resist the fire of light field-guns, whilst in others it will be sufficient if they serve as a cover to the men within them against musketry. This latter cover is that which, when time for more does not avail, is thrown up at the close of a march, after taking up a position, and which, if the army does not

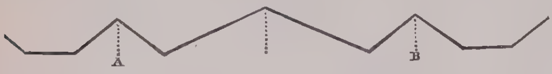


AB varies from 180 to 400 yards.

FIG. 44.—Lines of Redans.

move next day, may be strengthened in parts, according to circumstances.

Continued Lines, or connected works, are resorted to in order to inclose the front of a position, or to connect important works or forts. The most simple trace is that of redans joined together by curtains (fig. 44); the ditches of these curtains can only be defended by an oblique fire from the faces of the redans, but this defect may be remedied by breaking the curtains so as to form nearly right angles with the faces of the redans, in which case they are called "Lines of Tenailles" (fig. 45).



AB varies from 300 to 600 yards.

Fig. 45.—Lines of Tenailles.

"Lines en Crémaillère" have long faces, with flanks perpendicular to them, in order to defend their ditches (fig. 46). When the faces can be directed towards ground upon which it is impracticable to establish enfilading batteries, this trace is good.

Fig. 46.—Lines en Crémaillère.

Bastioned Lines (fig. 47) form the strongest trace which can be given to continued lines, when the ground will admit of its adoption. A perfectly regular trace can only be applied to level ground. The ditches in field-works are often sloped *en rampe* towards the adjoining flanks, in order that the "deblai," or quantity of earth excavated, may not exceed the "remblai," or quantity in the mass of the rampart or parapet, a condition which might otherwise occur in field-works, where there is seldom any rampart, and only cover sufficient for the defenders.

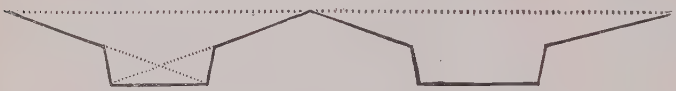


Fig. 47.—Lines of Bastions.

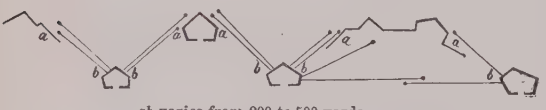
Fig. 48 shows the general trace of "Lines with intervals."



ab varies from 200 to 500 yards.

Fig. 48.—Lines broken or with intervals.

The salient works should never be beyond the range of musketry from the re-entering works, and the angles of defence between the two lines should be as nearly right angles as possible.

"Têtes-de-pont," or Bridge-heads, are works, open at the gorge, whose flanks rest upon a river, designed to cover one or more bridges. The best situation for these works is the re-entering sinuosity of a river. As Têtes-de-pont (fig. 49) are usually constructed for the purpose of enabling a retiring army to cross a river in order, and to check an enemy pressing upon it, their trace and profile should be such as to secure this double advantage to the greatest extent possible. In Sir Howard Douglas's able work on the *Construction of Military Bridges* will be found much valuable information upon this important subject.

The obstacles which are usually added to field-works, in order to render the approaches more difficult to the enemy, such as shelter trenches, entanglements, palisades, barriers, abattis, trous-de-loup, chevaux-de-frise, harrows, and crows' feet, have been already described.

Defence of Open Towns and Villages (fig. 50).—To admit of a town being advantageously intrenched it is necessary that it should not be commanded within range of field-guns, that its houses should not be of a construction easily set on fire, such as of wood with thatched roofs, and that its extent should not be out of proportion to the means and time at the disposal of the defenders. The last consideration is of much importance and should be well weighed, as this kind of defence is prodigal of men. It is however rapidly organized; and, as the number and the nature of the troops allotted to it are effectually concealed, it is susceptible of being prolonged obstinately. When time presses the first step is to occupy the outer inclosures and to bar the principal thoroughfares upon the enemy's side, to construct abattis and shelter trenches, to loophole the buildings flanking the barriers, and then to form a strong "shooting line" behind the outer inclosures, clearing enough of the ground in rear to receive the supports and reserves, and to enable them to act efficiently either in assisting to expel the enemy or in covering the retreat. The approaches to the "shooting line" should be cleared for a distance of at least 300 yards, by levelling houses, hedges, shrubberies, filling ditches, and clearing away whatever may favor the assailants. Wood should be cut down about 2 ft. 6 in. above the ground, and with wire or other means formed into an entanglement; hedges may often be so formed into most effective entanglements. The squares and open places should be occupied by the main reserves; the main approaches should be subjected to artillery fire; and distinct communications should be formed for the retreat of the defenders of the "shooting line." The inclosure round the town should be completed, and for this purpose some houses should be removed, others should be loopholed, streets should be barricaded, secure places found for the magazines, and cover provided for the main supports and reserves, and wide and easy communications laterally and to the rear should be made. Streets leading out of town should be barricaded. The barricades should be sufficient to resist field artillery, and high enough not to be easily surmounted; and they ought to be flanked by loopholing the neighboring houses. When time presses, carts filled with dung with the wheels removed, sand-bags, bales of wool or cotton, and furniture taken from the neighboring houses can be used as barricades. A church, a manufactory, a town-hall, a market, or any large substantial building should be converted into a keep, by blocking up useless entrances, loopholing its walls, and surrounding it by a ditch or abattis. Loopholes are slits or notches cut in walls with such tools as may be at hand. They are usually about 3 inches wide and 12 inches long externally, and are splayed internally so as to allow variation in the direction of the fire. Loopholes are cut vertically or horizontally as the case requires, and are much used as temporary means of supplementing the cover afforded by the parapets of temporary and permanent works; they are then formed of any materials at hand, such as sand-bags, logs of wood, and brush-wood. Sand-bag loopholes are the best, as the whole loophole is not necessarily destroyed by the blow of a projectile, and they are easily moved from place to place; two sand-bags are placed side by side with an interval between them, and a third covers this interval. Logs of wood are disposed similarly; brushwood or board loopholes are embedded in the parapets. If a town is situated near a stream or river, by which part of it may be covered by inundations, the resources this affords should never be neglected.

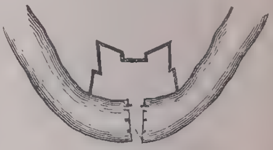


Fig. 49.—Tête-de-pont.

Villages are intrenched on similar principles, and being generally surrounded by gardens with live hedges, the latter may be made use of in the lines of defence. If there should only be sufficient troops to defend part of a village or town, a part of it only should be intrenched, and should be separated from the rest by means of carts and barricades. If there are very few houses, it may be necessary to confine the defence to the church or churchyard. Villages are often in one long street; then only the rear portion is intrenched, clearing in front of this portion a space sufficient for the effective action of musketry.

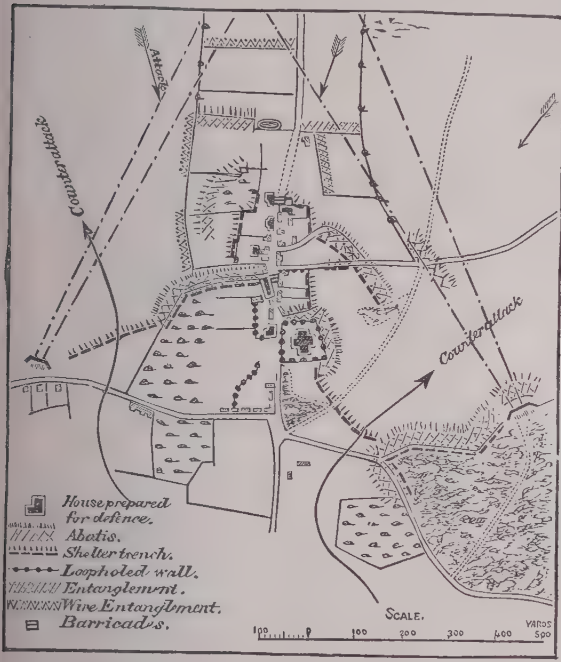

Fig. 50.—Illustrating Defence of Towns or Villages.

The Destruction of Bridges.—Nothing is of greater consequence to a retreating army than to destroy the bridges in its rear, in order to retard the advance of the enemy. Its existence may depend upon the success with which this operation is performed. To destroy a stone bridge with gunpowder a trench in the form of a cross is made in the crown of the arch, the branches of which are about 10 feet in length, and sunk to the top of the arch-stones. For an arch 3 feet thick, 160 ℔ of powder are placed in each trench; strong planks are then laid over the powder, and covered with rubbish. The fire is communicated by means of powder-hose or Bickford's fuze. Stone bridges are destroyed also by simply cutting a trench about 18 inches deep across the crown of the arch, and placing in it 345 ℔ of powder covered in the manner just described. This quantity has been found sufficient to destroy semicircular arches of 25 feet span, and of 3 feet in thickness at the key. Wooden bridges may be destroyed in various ways; they may be pulled to pieces, burned, or blown up. When there is time to take them to pieces, they are unspiked, and the timbers so separated that they may be speedily removed. The best method of burning such bridges is to tar them, and then to cover and surround them with fascines or tarred brushwood. Wooden bridges may be blown up by large charges of powder suspended under the superstructure, and fired in the manner above described. But these and other hasty demolitions may be more quickly and more certainly effected by the use of Compressed Gun-cotton, which is, weight for weight, four times as strong as gunpowder, and requires no tamping. Compressed gun-cotton is stored damp, and in this state it is perfectly safe for transport and handling, as it can only be detonated by the agency of a small quantity of dry gun-cotton, called a primer, and a detonator. The detonator is fired in the ordinary way or by electricity. Compressed gun-cotton is made in many convenient forms and sizes, such as 1 oz. and ½ oz. discs, 1 ℔ or 2 ℔ slabs, pellets, and grains. Generally it should be evenly distributed over the surface of stone bridges—if heaped, it forces an opening clean through. Supports of timber bridges may be destroyed by a girdle of half-ounce discs tied round them; or, if time avails, by charges placed in auger holes bored in them; ½ oz. of gun-cotton is sufficient for each square inch of the sectional area of the support. Iron bridges are destroyed by attacking the bottoms of the piers, or, in the case of girder bridges, the junction of 2 girders; 2 ℔ of compressed gun-cotton per foot lineal laid against an 18-inch brick wall will destroy it,

A ford is rendered impassable by throwing large stones into it, by sinking boards with spikes standing upright in them, or by placing crows' feet or harrows in it. A low rubble wall may be formed across it, so as not to be perceptible above the water; strong stakes may be driven into the bottom, and trees fastened to them; wagons loaded with stones, with the wheels removed, may also be employed; and a number of other things which may often be found at hand will answer the purpose equally well. Rendering a ford impassable is only second in importance to the destruction of a bridge, when the enemy, whose progress it is desired to retard, either has no pontoon-train, or has outstripped it by the rapidity of his advance. By such expedients to retard the pursuit much valuable time may be gained by the retreating army.

The essential characteristic of all intrenchments which are formed of earth is that the musketry fire, on which the defence must mainly depend, being discharged over the crest of the parapet, the line of fire will be nearly in the plane of the superior slope of the parapet, and perpendicular to the line of its crest; and hence opposite a salient angle, as in the Redan (fig. 51), there will be a large space of ground in this case extending over 180° − 60° = 120°, undefended by the fire of the work itself; this space is called a "dead angle." Opposite re-entering angles, on the other hand, the defect is of a different kind, as the plane of the superior slope or plane of fire passing high above the foot of the escarp necessarily leaves it unseen and unprotected, notwithstanding that the two lines theoretically flank each other. The object, therefore, in arranging field works for mutual defence should be so to regulate their reliefs that the lines of defence should terminate at such distance from the ground as to give effective defence to the parts of the works intended to be flanked. The Redan may be considered the most simple form of *defensive* work, though a straight parapet terminating by short returns at each flank, in the form either of epaulements or of regular parapets, may occasionally be combined with defensive works. The redan is open in the rear, and the line joining B and C is called the gorge.

The "Lunette" is a redan to which flanks or lateral wings have been added; in form, therefore, it resembles a bastion.

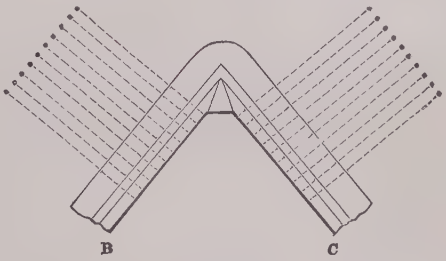

Fig. 51.—Redan.

In fig. 48 Lunettes are shown so arranged that the faces of those in rear may flank the faces of those in front; but with respect to the distribution and arrangement of the works destined to form Lines of Intrenchment more will be said hereafter.

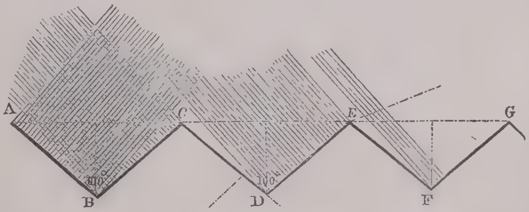

Fig. 52.—Tenailles.

The "Tenaille" is the reverse of the redan; it consists of two lines forming a *re-entering* angle facing the exterior. It can, from its form, only be used in direct or approximate connection with other works, which close up or cover the ends of its lines. Either alone or combined with redans it is very commonly used in continued Lines of Intrenchments. Fig. 44 represents a Line of Redans joined by straight lines, and fig. 45 a Line of Irregular Tenailles, whilst fig. 52 represents a normal Line of Tenailles, of which the re-entering angles do not exceed 100°, and the sides are equal, and fig. 53, an arrangement of Tenailles, with irregular sides, by which a Redan, as DEF, is interposed between every pair of Tenailles. The Line *en crémaillère* (fig. 46) is also derived from a combination of irregular tenailles, and is in many circumstances a very satisfactory arrangement. In selecting between these and other arrangements, including the bastion trace (fig. 47), the engineer must be guided by the nature of the ground and the special objects to be attained. A slight consideration is sufficent to show that the combination of regular tenailles in fig. 52 is only applicable to ground in itself regular. In most cases, however, the ground will be more or less irregular, and the works to defend it must be so also. When it is necessary to approach close to the bank of a river or a ravine, the Crémaillère Line (fig. 49) is the simplest and best, the short or flanking sides being so placed as to face the probable direction of approach, and next to that the combined Redan and Tenaille. Of open works, Lunettes admit of the most scientific arrangement, as they can be so placed in lines with intervals as reciprocally to flank each other, and thus to form a line of defence very similar to a regular bastioned line. The employment, however, of works open at the gorge must be restricted to positions where the enemy can only approach in front, his approach in other directions having been rendered impossible by obstacles or by other works. In every case it is desirable to take advantage of peculiarities in the features of the country, and to modify them into such obstacles as shall relieve the defenders from apprehension of danger, and leave them at liberty to direct their attention more exclusively to the weaker points of their position; but in no case should even apparently inaccessible points be left unwatched, as an enterprising and skilful adversary will at times surmount difficulties which had appeared insurmountable. As naturally defended points in a position can only be looked upon as exceptional advantages, it is evident that works left open at their gorges would be liable to surprise, and would therefore prove but imperfect instruments of defence. On this account it has been not unfrequently prescribed that such works should be left unclosed when within range of musketry fire from the defences behind them; but it is better to lay down the fixed principle that in all cases they should be closed at the gorge, as the power of driving an enemy out of the interior of such a work is of little value, for his object would be not to remain in its *interior*, but to turn its parapet to his own uses. The manner in which they are generally closed is shown in fig. 54, which is a lunette secured at its gorge by a loop-holed stockade, an obstacle effective against an enemy, and, at the same time, easy of destruction, should he succeed in temporarily obtaining possession of the work. Any of the obstacles previously described, such as abattis, etc., may be used for the same purpose, but they have the disadvantage of not covering the defenders of the work from the enemy's fire. An engineer in deciding between open works, such as have been described, and closed works such as will now be described, ought to take into consideration the circumstances of ground not only as affecting the security of the work itself, but as affecting the ease or difficulty with which support can at any moment be afforded to its garrison. Open works are not fitted for any position where they are likely to be left to their own resources, even for a short time, as small bodies of men cannot be expected to stand firm against a vigorous attack from a superior force, unless satisfied that support is at hand. Closed works, therefore, in which the parapet is continuous on all sides can alone be relied upon under such circumstances; and the nature of the obstructions adopted in their construction should be such as to afford the garrison a reasonable confidence that by a vigorous defence they may be able to hold the enemy at bay; for no general should expect to find in soldiers, as a body, that heroism which leads to self-sacrifice without hope. The easy capture of the redoubts at Balaclava garrisoned by the Turks is an illustration of this principle; for though it is possible that they might have been longer maintained by French or British soldiers, it would have been unreasonable to expect that their defenders should remain firm until overpowered and cut down by their assailants, which must have been the result had not a supporting force been at hand to relieve them. The rules may therefore be laid down, that in all detached works the mode and time of relief should be palpable to the garrison; that the nature of the constructions should inspire the garrison with confidence in its power of resistance for a reasonable time; and, above all, that the garrisons of such works should be composed of the best soldiers.

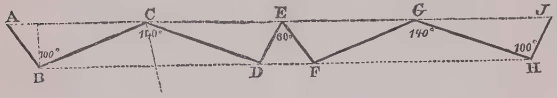

Fig. 53.—Combined Tenailles and Redans.

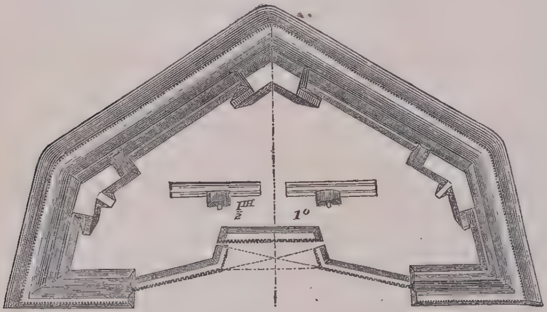

Fig. 54.—Lunette closed at the Gorge.

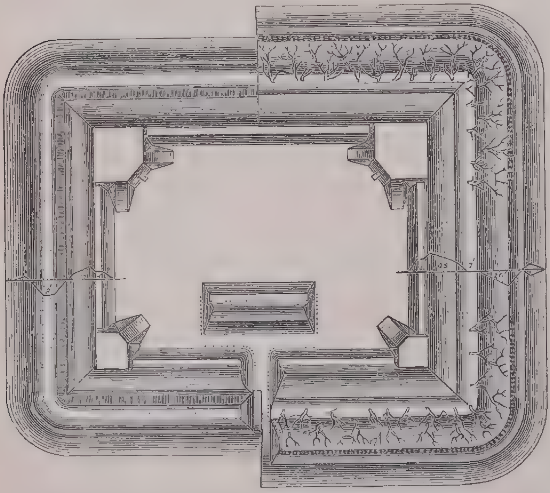

Fig. 55.—Rectangular Redoubt.

Redoubts, as has been said, may be either regular or irregular polygons of any number of sides, but the square redoubt is the most simple (see fig. 40). All redoubts have the disadvantage of "dead" salient angles; and it is usual, therefore, to place the guns used in their defence in the salients, so that their fire may be along the capitals or lines bisecting the salient angles, as well as upon the dead space in front of them. The sides should be made to front the probable line of approach, and, as shown in one half of fig. 55, which represents a Rectangular Redoubt, the escarp is sometimes sloped gently down to the bottom of the ditch, and covered with abattis or other obstacles, which can then be seen and defended in front by direct fire. It is indeed impossible to repeat too often that in all works the efficiency of defence must mainly depend on the power of arresting the progress of the assailants at those points which are under the fire of the defenders. The entrance to a redoubt should be made in the least exposed side, and be protected by a parapeted traverse placed behind it, as in fig. 55, where an arrangement of palisades is shown by which the traverse may be connected with the parapet of the works, and the entrance closed by gates or barriers. Traverses may be also constructed either for the purpose of defilade or for affording additional cover to the troops. They may be formed, when the work is sufficiently capacious, of long parallel epaulements, with a space between them, which can be covered over or blinded when it is likely that the work will be held for a considerable time, and when, in consequence, a more secure and comfortable lodging is desirable for the garrison. Magazines for ammunition may be constructed either against or in such traverses; and fig. 56 represents, in plan and section, a magazine behind a gabion traverse, and isolated from the parapet in front of it. This magazine is partly sunk in the ground, with sides of plank and a roof of strong timbers forming a ridge in the centre, covered first with fascines and then with 4 or 5 feet of earth. Its dimensions are—length, 8 feet, breadth 5 feet, height 6 feet.

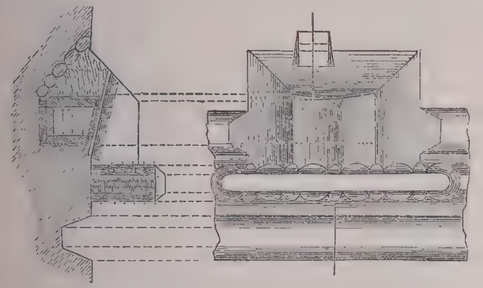

Fig. 56.—Plan and Section of Magazine behind a Gabion Traverse.

Having thus generally described this portion of the subject, it is necessary to determine the least size which can be given to redoubts, so as to ensure interior space sufficient to accommodate the garrison required for the defence of the parapet, remembering that in works not provided with flanking defences the whole parapet, unless secured in part by some insurmountable *natural* obstacle, must be defended.

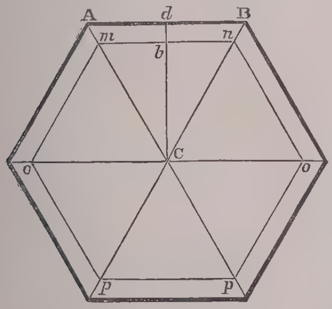

Fig. 57.

A general formula may be easily obtained for determining the least regular polygonal trace in the following manner:—

Let x be the side in feet of any regular polygon, n the number of sides, A the interior surface reckoned from the foot of the banquette, y the number of men forming the garrison, f the number of linear feet allotted to each soldier, F the number of square feet occupied by each man in the interior—then

$$fy = nx, \text{ and } \mathrm{F}y = \mathrm{A}, \text{ or } y = \frac{nx}{f} = \frac{\mathrm{A}}{\mathrm{F}}; \text{ whence } \frac{n\mathrm{F}x}{f} = \mathrm{A}.$$

Again, let the perpendicular Cd, from the centre of the polygon (fig. 57) to its side AB, be p, and let the distance db from the side AB to the boundary line of the available interior space mn be d; then $\mathrm{C}b = p - d$; and as $\mathrm{C}d : \mathrm{AB} :: \mathrm{C}b : mn$, $p : x :: p - d : mn$, or $mn = \frac{px - dx}{p} = x - \frac{dx}{p}$. Now, the value of p expressed as a function of x and of the angle of the centre ϕ, which is $= x \, \frac{1}{2} \cot. \frac{1}{2} \phi$, varies with the nature of the polygon; and replacing therefore the variable coefficient $\frac{1}{2} \cot. \frac{1}{2} \phi$ by β, we have $p = \beta x$, and mn, the side of the interior space $mnpo = x - \frac{dx}{p} = x - \frac{dx}{\beta x} = x - \frac{d}{\beta}$, and $\mathrm{C}b = mn \times \frac{1}{2} \cot. \frac{1}{2} \phi = \beta\left(x - \frac{d}{\beta}\right)$. The surface of the interior triangle $\mathrm{C}mn = \frac{1}{2} mn \times \mathrm{C}b$ is thus $= \frac{1}{2} \beta \left(x - \frac{d}{\beta}\right)^2$, and $\mathrm{A} - \frac{n\beta}{2}\left(x - \frac{d}{\beta}\right)^2$; whence also $\frac{n\mathrm{F}x}{f} = \frac{n\beta}{2}\left(x - \frac{d}{\beta}\right)^2$, and thence by reduction $x = \frac{1}{\beta}\left\{d + \frac{\mathrm{F}}{f} + \sqrt{\frac{\mathrm{F}}{f}\left(2d + \frac{\mathrm{F}}{f}\right)}\right\}$. The values of the variable $\beta = \frac{1}{2} \cot. \frac{1}{2} \phi$ are as follows:—

In the	triangle,	0·288
"	square,	0·500
"	pentagon,	0·688
"	hexagon,	0·866

Taking the square, and supposing we have $d = 12$ feet, $f = 3$, $\mathrm{F} = 6 \times 3 = 18$, $x = 62·81$ feet (21 yards), which may therefore be taken as the side of the smallest square redoubt to be defended by one rank only of soldiers, the garrison being 84 men in single rank, and a reserve equal to one-third of the garrison; if $f = 2$, then $x = 76·66$ feet, or nearly 26 yards, the garrison being 156 men. If there are to be two ranks, $f = 1\frac{1}{2}$, and $x = 89·6 = 30$ yards nearly, the garrison being 240 men; and if two ranks, with a reserve equal to one-third of the whole garrison, $f = 1$ and $x = 115$ feet, or about 38 yards, the garrison being 456 men.

Triangular Redoubts are rarely used, as their interior space is small and out of proportion to the length of parapet; thus the smallest triangular redoubt to be defended by two ranks should have a side (x) 54 yards in length, and a garrison of 324 men, the total length of parapet required for this force being 162 yards; whereas a square redoubt of 38 yards side, which has a total length of parapet of only 152 yards, will accommodate a garrison of 456 men, admitting a "two-rank" defence, with a reserve of one-third the whole garrison. Another objection to Triangular Redoubts is the great amount of dead-angle space before the salients. Keeping these figures in recollection, the engineer will readily be able to determine his arrangement of the proposed garrison, and to limit himself to the least amount of work in parapet. If, however, he has to provide, in addition, for guns, for traverses, and for other constructions, he must increase the side of his square, bearing in mind that in the square of 38 yards side the augmentation of 1 yard per side adds only 12 men to the garrison, raising it to 468, whilst it adds 549 square feet to the interior space; so that, as the 12 men require only 216 square feet, there will be an addition of 333 square feet towards the additional provision specified. And if the side be increased to 45 yards, and the garrison to 540 men, there will be a surplus interior space of 2709 square feet, being sufficient for barbettes, for three guns and one howitzer, and for a traverse; this size may therefore be assumed as the best for a normal redoubt. It has been usual to assume that a redoubt should not have more than 180 yards of parapet, but there does not seem to be any reason for this assumption; and it may be said with confidence that a redoubt with double this extent of parapet will be superior to a field fort of the same strength of garrison, even though the fort has the theoretical advantage of reciprocal defence. The ditches of larger redoubts are sometimes, when circumstances admit, defended by Caponnières (fig. 58) placed either at the angles or in the middle of the sides. These caponnières are built of timber and roofed with logs or fascines, covered with earth; occasionally the ditches are defended by counterscarp galleries at the angles, constructed of the same materials as the caponnières, but buried in the counterscarp. Access is obtained by galleries revetted with timber descending from the interior of the work into the caponnière, and beneath the ditch to the counterscarp galleries. In fig. 40, one of the angles is shown with an indented parapet as a means of correcting the defect of a dead salient; but this is difficult of construction, and it will generally be preferable either to cut it off as in another angle of the figure, or to round it as in a third, or to occupy it by a gun *en barbette*, as in the fourth. Of Forts, fig. 41 exhibits a Star-Fort of eight points formed upon a square, which is far preferable to one of six points formed upon a triangle, as giving comparatively more available interior space. The defect, however, in this trace is that, though the intermediate angle F is sufficiently open—as it exceeds 60°—the angles A and B are less than 60°. Down to the lowest limit of such forts, in which AB of fig. 41 is taken at 60 yards, and the sides AE, EF, EB at 20 yards, there is still sufficient space to accommodate the necessary garrison, which should be in that case about 900 men. It is useless to describe those forms of star-forts which would not accommodate the required garrisons; but that represented in fig. 59 is well fitted for a large garrison. The following is a simple construction on a pentagon. Bisect AB in C; make the perpendicular CP $= \frac{1}{5}$ AB; join AP and BP; make B*d* and A*d* each $\frac{5}{12}$ of AB, and join *dc*, *dc*. In this case the angles at A and B will be 64°, and the short sides (with an exterior side of 120 yards) each 23 yards. From what has been already aid, Demi-bastioned Forts (fig. 43) will rarely be used; but when the proposed garrison requires a large amount of accommodation, and there is time to undertake such works, the bastioned trace should be adopted, as it introduces a principle not observed in the preceding traces, namely, that of defending the whole by a part, the opposite flanks EG, FG (fig. 42) of the two bastions GEAEG, GFBFG defending the intervening curtain GG between them, as well as the faces AE, BF of the bastions—whilst the fire of one flank necessarily sees the escarp of the opposite one and defends it. The bastions are indeed, like their analogous lunettes, works in themselves, the curtain being only a connecting line, forming several bastions into one connected whole. Fig. 42 is a square bastioned fort, but the pentagon is a better form, and should be adopted when practicable. The bastioned form of field forts has been derived from the more massive structures adopted in the permanent defences of fortresses, and its history, so interesting in itself, will be given in a future page. Little further need be said on this section of the subject, except to point out the great importance of field-works in securing a base of operations for an advancing army. Fig. 49 (page 384) exhibits, for example, a bridge head consisting of a bastioned front, with either simple straight branches or branches with a short flank, as shown in the figure (see also fig. 60). This is technically called a Horn Work; and if there had been two such fronts so placed as to throw a bastion in the centre, and connected as before with the river by straight branches, the work would have been called a Crown Work. Lunettes and even Redans may also be used, as in left side of fig. 36, for a similar purpose, where the object is first to secure the bridge from the enemy's attack and fire, and secondly to allow the defending army to manœuvre on the opposite side; but in proportion to the numbers to be passed over the bridge, and to the extent of advance contemplated, it will be necessary either to increase the importance of the works forming the bridge head, or to form more than one bridge in connection with them. Nothing can be more fatal to a retreating army than to be driven back upon a river without a line of intrenchment sufficient to enable it to maintain its ground whilst its arrangements for passing the river are in progress. Fig. 60 exhibits one such arrangement, in which the Horn Work front has been much enlarged, and a lunette as a keep introduced within it. The mode in which the troops can move out at the sides, under protection of covering and flanking parapets, is shown, as well as the barbettes for guns, which become necessary in works having so important an object. Fig. 61 represents a line of Tenaille Intrenchments in front of the lunette, and a line of intrenchment on the near side of the river, from part of which the last terminal branches of the tenailles are flanked. In this figure T, T represent traverses, and F, F either chains or lines of pickets placed across the stream,—the object of the first being to secure the bridge from the ricochet fire of the enemy, and of the second to secure it from destruction by burning or explosive bodies launched by the enemy up the stream, to float down upon the bridge. More extended intrenchments might be formed of lines of lunettes with intervening intrenchments; but it is unnecessary here to pursue the subject further, as the engineer must necessarily adapt his works to the nature of the ground, and to the strength of the army for which he is required to prepare a defensive position, from which it may either advance or retire, without risk or confusion, as the necessities of war may require.

Permanent Fortification.

If, as has been stated, simple lines or works of fortification have been adopted even by the rudest tribes of wandering savages for their temporary defence or security, the more massive and artistic works of permanent defence would seem to imply a certain amount of civilization. As an art, indeed, Fortification is almost co-existent with society. When men first assembled together for mutual protection, and placed their habitations in one spot, the law of necessity, springing in this case from the principle of self-defence, rendered it indispensable for them to adopt means for securing their families and their property against the sudden inroads of enemies. In the early ages men were sufficiently protected by a wall, from behind which they could with safety discharge darts, arrows, and other missiles against an assailant. But when, in the progress of improvement, new and more powerful means of attack were discovered, it became necessary to increase in a corresponding degree the power of resistance; and so it came to pass that the feeble defensive structures of primitive times were superseded by solid ramparts, flanked and commanded by elevated towers; and, as the power of attacking fortresses or places of strength became augmented by successive devices and inventions, so the means of resistance became proportionally increased, until the art of Fortification arrived at a state of comparative perfection, in which for many ages it remained nearly stationary.

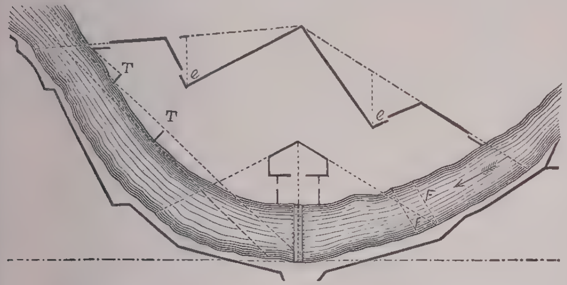

FIG. 61.—Tenaille Intrenchments protecting Bridge.

The various improvements which were from time to time made in strengthening the walls and in adding to the defences of ancient cities, are recorded in history, and need not be detailed in this place. The first walls of which we read were of brick. Amongst the ancient Greeks, brick and rubble stones intermixed were used, as we find from the description of the wall which connected Mount Hymettus with the city of Athens; but surrounding several cities were works of Cyclopean character, built of huge stones, without mortar, placed with their longer axis transversely to the line of wall, and arranged with great care and skill. The walls of Babylon and Nineveh indicate a prodigious advancement in the art of Fortification, and are justly accounted amongst the wonders of the ancient world. Those of the former city, ascribed by some to Belus, and by others to Semiramis, were thirty-two feet in thickness, and one hundred feet in height, surmounted at intervals by towers ten feet higher, and cemented by means of bitumen or asphaltum; they encompassed a vast area, and presented a solid defence, which no means of attack known in ancient times were sufficient to overcome or beat down. The walls of Jerusalem, though of smaller dimensions, appear to have been little inferior in strength and solidity to those of Babylon; for, in the siege of that capital by Vespasian, all the Roman battering-rams and other engines, though used with the utmost vigor through a whole night, only succeeded in disengaging four stones in the masonry of the tower of Antonia. But after Fortification had arrived at the state in which we find it in the works of these and other cities, it remained stationary for ages, and perhaps even retrograded somewhat, until the discovery of gunpowder, the invention of artillery, and the application of both to military purposes, effected an entire revolution in the principles of attack and defence. Then the towers, which had formed secure flanking defences against assailants armed only with arrows and darts, no longer afforded protection against projectiles discharged from cannon; and even those battlements which had defied the catapult and the battering-ram speedily fell before the new force with which they were assailed, burying their defenders in their ruins.

The ancient system of Fortification being thus found of little avail against the new method of attack which came into general use towards the close of the fifteenth century, it became indispensably necessary to adopt improved methods of defence. The plan of fortifying with bastions is believed to have originated with the Italians early in the fifteenth century; though Papacino D'Antoni, professor of artillery and engineering of Turin, states, in *Architettura Militare* (1759), that several small bastions had been constructed in the preceding century, and that the ruin of a large bastion which had formed part of the fortifications of Turin, built for Duke Louis of Savoy, still existed in the royal gardens at that time. The bastions on the enceinte of Verona, built by the Italian engineer Micheli, in the year 1523, are generally supposed to be the oldest extant; and the next, probably, are those of the citadel of Antwerp, which were constructed for the emperor Charles V. in 1545, by the Italian engineer Paciotto D'Urbino. These bastions are small, with narrow gorges and short flanks and faces, and are placed at great distances from one another, it being the invariable practice, at the time when they were built, and for a considerable time afterwards, to attack the curtains, and not the faces of the bastions.

Errard of Bois-le-duc was the first in France who laid down rules respecting the best method of fortifying a place, so as to cover its flank. He was one of the principal officers of the engineers in ordinary to the king, a corps formed by Sully, who was grand master or master general of artillery in the reign of Henry IV., out of the best instructed and most experienced military men. This corps is now the Corps de Génie, and to this day maintains its scientific character. At the command of the minister, Errard wrote a book on the subject, which was published in 1594, and in which the details of his method are explained. As a writer on Fortification, he was preceded in France by Beril de la Treille, who published his work on fortifying towns and castles in 1557. Errard fortified inwards; and in the square, pentagon, hexagon, heptagon, and octagon he made the flank perpendicular to the face of the bastion; but in the enneagon, and in polygons of a greater number of sides, he made it perpendicular to the curtain. In his method, however, the gorges are too small, the embrasures are too oblique, and the ditch is almost defenceless. This engineer constructed part of the enceinte of the citadel of Doutens, the citadel of Amiens, and some works at Montreuil and Calais.

Antoine de Ville, who succeeded Errard, published a treatise, dated 1629, in which he completed much that his predecessor had only sketched, and rectified various defects in the method of the latter. He was employed under Louis XIII., and constructed new enceintes for Montreuil and Calais. His method of fortifying has been denominated by some the French Method, and by others the Compound System (*Système à trait composé*), because it united the Italian and Spanish methods, from the latter of which it differs only in having no second flanks and fichant lines of defence, and in not confining the flanked or salient angle of the bastion to ninety degrees. The leading maxims of De Ville were to place the flanks perpendicularly to the curtain, to make them equal to the demigorges, or a sixth part of the side of the interior polygon, and, in the hexagon and all higher polygons, to confine the flanked angle to ninety degrees. But this method is liable to nearly the same objections as that of Errard, as the embrasures are too oblique, especially in the polygons, and the ditch is ill defended.

In 1645, sixteen years after the publication of De Ville's, appeared the treatise of the Comte de Pagan, which contained the development of a system that, in a short time, entirely superseded those of his predecessors. It was the Comte de Pagan who first disengaged the science of Fortification from a number of suppositions which custom had consecrated, and which, resting more on abstract mathematical reasoning than on practical experience, had hitherto retarded the progress of the art. This engineer served at twenty-five sieges with great reputation; but having become blind at the age of thirty-eight, he was obliged to retire from the service, in which he had already obtained the rank (then second only to that of marshal of France) of mareschal-de-camp, and he died six years after completing the treatise above mentioned. He had from his earliest years devoted himself to the study of mathematics and fortifications, and he published several works on astronomy besides his celebrated work on Fortification. Pagan made the flank perpendicular to the line of defence, in order as much as possible to cover the face of the opposite bastion; and he devised a method of building casemates peculiar to himself. Vauban borrowed from Pagan the length of his perpendicular, and Allain Manesson Mallet, whose construction has found much favor, proceeded upon the principles Pagan had laid down.[1]

[1] Mallet constructed outwards, making in every figure or polygon the demigorge equal to a fifth part of the side of the interior polygon

The Mareschal de Vauban was born in 1633; and at the time of the Comte de Pagan's death, he had already acquired reputation at several sieges. Vauban followed up the principles suggested by Pagan, and employed them extensively, with consummate skill and judgment. He constructed 33 new fortresses, repaired and improved 100, and conducted about 50 sieges. His extensive works, especially the treatise *De l'Attaque et da lu Défense des Places*, published in 1737, speak for themselves. From these works have been compiled the systems which, in the military schools, are denominated Vauban's first, second, and third systems of Fortification, and which the reader will find developed in the sequel. Had the genius of Vauban been applied to the discovery of a method for securing a permanent superiority to the defence of fortified places, posterity would have been greatly indebted to him, and even humanity would have had cause to rejoice in such a triumph of military art. But, being engaged in the service of the most ambitious monarch of modern times, Louis XIV., he applied his great talents to forward his master's views, and perfected that irresistible system of attack[1] which has ever since been so successfully followed. Before his time the superiority was on the side of the defence; but he so completely reversed the case that the success of an attack, conducted scientifically and with adequate means, has been until the present time a matter of certainty.[2] Vauban was no ordinary man in any sense. As the inventor of parallels in sieges, and of ricochet fire, he stands in the first rank of military engineers; and as he conducted 53 sieges, and took part in 140 battles and skirmishes, it must be admitted that in respect of experience he stands in no inferior position. At fifty-five years of age he attained the highest honor of the French army, being created marshal of France; yet amidst his stirring and successful military life he never ceased to turn to account the geometrical knowledge for which he was distinguished when a youth, and which had obtained for him the early notice of the Prince de Condé. His mind was never idle, and was constantly directed to projects of public utility, civil as well as military; and he left behind him records of such labors in 12 folio manuscript volumes, entitled *Mes Oisivetés*, a wonderful monument of his ability and industry.

M. Minno, Baron de Coehorn, first a general of artillery, then a lieutenant-general of infantry, and ultimately director-general of all the fortified places belonging to the United Provinces of Holland, was the contemporary and rival of Vauban. This able engineer, convinced that, however expensively the rampart of a town may be constructed, it cannot long resist the shock of heavy ordnance, invented three different systems by which such obstacles are thrown in the way of a besieging force that, although the place be not thereby rendered impregnable, it can only be reached with great difficulty and hazard. But these systems, without modification, are only applicable to low and swampy situations, such as are to be found in Holland, and are therefore not available in localities of a different description. Nevertheless, Bergen-op-Zoom, Mannheim and other places fortified by this engineer, particularly the two named, have very great merit, inasmuch as it is impossible for a besieger to penetrate into any of the works without being exposed, on all sides, to the fire of the besieged, who are under cover, and from whose artillery and musketry fire it is scarcely possible for an assailant to shelter himself. In fact, Coehorn was a great master, and combined with the bastioned trace, as will be explained when his system is noticed, many of the means of defence springing from another source. He published his first work on Fortification before he had acquired much experience; and in fortifying Bergen-op-Zoom, which is allowed to be his masterpiece, he did not reproduce, except in fragmentary details, any of his published systems.

Since Vauban's time several improvements have been suggested, particularly by Cormontaigne, who entered the corps of French engineers in 1716, nine years after Vauban's death, and died a mareschal-de-camp in 1750. Some account of the system of Cormontaigne will be found in a subsequent part of this article. The three methods enunciated by Belidor are all applicable to an octagon of 200 toises. Scheiter distinguished his systems as great, mean, and little, in imitation of Pagan, requiring the exterior sides of the polygon to be 200, 180, and 160 toises respectively. He adopted from Castriotto detached bastions, and made use of a continuous fausse-braye. Fritach, a Pole, proposed two methods, which he exemplified on different polygons. Dogen, a Dutchman, after enumerating, in a large volume on Fortification, various modes employed by different writers for determining the salient angle, selected three as most worthy of approval, and proposed as many methods of construction, one of which is borrowed from Fritach, the Pole. Pietro Sardi, an Italian, suggested a peculiar method of construction on a hexagon. The Sieur de Fontaine found the flanked or salient angle of the bastion by adding 15° to half the angle of the figure, from the square up to the dodecagon, in which last it becomes 90°, and at this he continued it in all the higher polygons. He also constructed outwards, and, in every regular figure, made the curtain equal to 72 toises, the face of the bastion to 48, and the flank, which he placed perpendicularly to the curtain, to 18 toises, or a fourth part of the curtain. Ozanam and Müller delivered each four methods of construction, the particulars of which will be found in their respective works. In 1751 Charles Bisset, who, as engineer-extraordinary, served with the duke of Cumberland in the Netherlands, and was present during the siege of Bergen-op-Zoom by Marshal Lowendahl, published a treatise on the theory and construction of Fortification, in which there are many sensible and judicious remarks; and this may also be said of an *Essai sur la Fortification, ou Examen des Causes de la grande supériorité de l'Attique sur la Defense*, published anonymously in 1755. In a work entitled *Science de la Guerre*, which appeared at Turin in 1747, a new method of construction is proposed, in which the principal novelties are mines under all the works, and regular communications with them by means of subterraneous galleries, to be resorted to as the enemy approaches the body of the place. The third volume of the *Œuvres Militaires* contains useful observatious and maxims relative to irregular Fortification; and in the supplement to the *Rêveries* of Marshal Saxe, by Baron d'Espagnac, the subject of Fortification is amply discussed, and an accurate description given of the different means of attack and defence. Besides the writers above enumerated may be mentioned the Chevalier St. Julien, an able engineer, who published a method by which, he asserts, works may be constructed at less expense, yet in such a manner as to render the defence more formidable; Francisco Marchi, of Bologna, who in 1599 furnished no less than 139 different methods of constructing fortifications, many of which are valuable, and from which subsequent engineers have greatly profited; Bombelle, who established three kinds of Fortification, called the grand royal (*grand royal*), the mean royal (*moyen royal*), and the little royal (*petit royal*); Blondel, who published a system divided into two principal heads, the great and the little, whose exterior sides are respectively 200 and 170 toises; Donato Rosetti, a canon of Leghorn, who wrote on the method of constructing works in what he calls *Fortification à rebours*, or Fortification in reverse, so denominated because the re-entering angle of the counterscarp being opposite to the flanked angle, it will, according to him, be necessary to attack it from the reverse side of the other works; and Antonio de Herbart, major of artillery in the duke of Würtemberg's service, who published a treatise on Fortifications with what he calls *angular polygons.* The treatise entitled *Nouvelle Manière de fortifier les Places, tirée des méthodes du Chevalier de Ville, du Comte de Pagan, et de M. Vauban, avec des Remarques sur l'ordre renforcé, sur les desseins du Capitaine Marchi, et sur ceux de M. Blondel*, which appeared in 1689, is full of strong reasoning, whence the author deduced a new system; but it contains little that is original, though it gives numerous references to what had previously appeared, and disposes the different parts in a judicious manner. M. de Montalembert's system of casemated and reverse fire has been in part adopted in the splendid fortress of Alessandria, in Italy, which was constructed under the direction of Napoleon.

---

or figure, the capital of the bastion equal to a third part of the same side, the curtain equal to three-fifths or thrice the demigorge, and the angle of the flank equal to 98°. The faces of the bastions and the flanks are determined by the lines of defence, which are razant. From these data all the other lines and angles are easily found.

[1] See his work *De l'Attaque et de la Défense des Places*, passim.

[2] The protracted siege of Sebastopol is no exception to this rule. The length of its resistance was due to the fact that the resources at the disposal of the allied armies did not suffice for its investment, and that the Russians were in consequence able to introduce at their pleasure reinforcements of men, material, and provisions; indeed, at times they were more numerous than the attacking force.

Of the more recent treatises on fortification, that of M. de Bousmard, entitled *Essai Général de Fortification, d'Attaque et de Défense des Places, dans lequel ces deux Sciences sont expliquées et mises l'une par l'autre à la portée de tout le monde*, is very elaborate and complete, and enjoys a deservedly high reputation for accuracy and research.

Carnot's *Traité de la Défense des Places Fortes* was written to serve a temporary purpose; and the exaggerated celebrity which it acquired on its first appearance has been succeeded by an equally unfounded neglect. The more prominent innovations recommended in this treatise were —first, an alteration, which, however, was not original, in the trace or outline of the polygon; secondly, the suppression of the exterior revetment of the covered way, known as the counterscarp; thirdly, the detachment of the escarp-wall from the rampart, and the construction of the latter without revêtement; fourthly, destructive personal conflict with the besiegers by means of frequent sorties; and, lastly, vertical fire as the basis rather than the accessory of the defence. With regard to these innovations, all of which the reader will find ably discussed in Jones's *Journals of Sieges in Spain and Portugal*, vol. ii., it may be remarked that by means of an increased expenditure for retrenchments and casemates, as recommended by Carnot, the strength of particular portions of the polygon may be increased; and that, if he has failed in tracing a perfect front, founded on the basis of Montalembert's system of casemated and reverse fire, he has at least rescued a valuable suggestion from unmerited neglect, and rendered an important service to science by directing the attention of military men to means likely to create a barrier against the growing powers of the attack.

The *Traité de Fortification Souterraine, suivi de quatre Mémoires sur les Mines*, by M. Mouzé, lieutenant-colonel of engineers in the French service, published at Paris in 1804, is the most complete work on the subject of which it treats which has yet been given to the public. Subterranean Fortification is a branch of the art which, until recently, was wholly neglected in England, and in which British engineers were far behind their brethren of the Continent. We learn from Colonel Jones's work on the Peninsular sieges that the duke of Wellington's army in Spain was without a trained sapper or miner until late in the year 1813. In this respect things are now changed, and in the Engineers the army has the assistance of a body of men well instructed in the duties of the trench, the sap, and the mine, though it cannot be said even now that the corps of Engineers is of sufficient strength. Nor can this corps, as some contend, be supplemented by civil labor in time of war. Discipline is the foundation upon which the whole military system rests, and the highest skill, unless strictly subordinated to it, will avail little in war. The undisciplined laborer, who, under ordinary circumstances, would have worked with the greatest effort, would be found worse than useless if forced to work on his knees in a sap, exposed to an enemy's fire, or upon his back in a countermine, with the knowledge that the enemy's miner, though he cannot fix his precise position, is probably within striking distance.

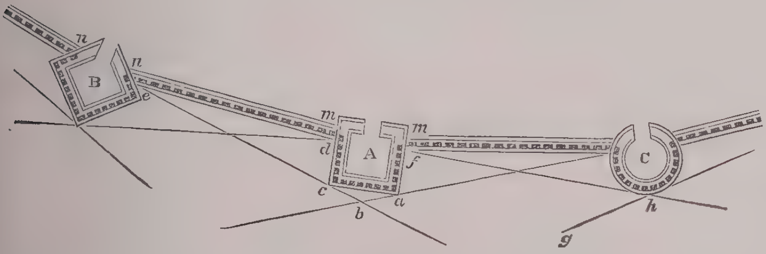

Fig. 62.—Illustrating the Growth of the Bastion.

Before going further it is desirable to recur to the earlier methods, and to investigate the manner in which the ancient arrangement of a wall, with round or square towers, passed into the present systems of defence. Fig. 62 will explain the natural and probable manner in which the old tower or rather tower-fort (*baluardo*) grew into the pentagonal bastion. If, for example, lines of defence be drawn from the extremes of two adjacent curtains to the angles *a* and *c* of the square tower-fort A, a space would be left, *cba*, unseen from the adjacent forts B and C, and therefore undefended, except by downward or vertical fire from machicoulis, or projections from the walls supported by corbels made for the purpose. Such a space would be turned to account by the besiegers in fixing their scaling-ladders; and the change of the straight line *ac* into the two faces *cb*, *ab* seems but the result of a self-evident necessity. As the work became enlarged, the portions of the fort within the connecting walls *m*, *m* were omitted, and the flanks *dc*, *fa* alone remained of the old wall, forming with the faces the bastion *fabcd*, which only required to be improved in proportions to become the bastion of modern times. It is, however, said that the towers were sometimes placed with an angle salient as in B, and if so, omitting the portions *nn*, the resulting bastion has a strong analogy to those of Errard before mentioned. By using the old wall merely as a retaining wall, and as an obstacle against escalade, and adding to it a rampart and a parapet of earth, the Italians completed the system of bastioned defence, which, notwithstanding all the modifications of the French, ought to be called the Italian system. In this system, whilst imitating the construction of the old towers by using casemated or masonry-vaulted chambers for artillery, in addition to the guns mounted on the rampart, the Italians placed the musketeers on the banquette of the parapet, and made them fire over it. Now this arrangement of the musketry fire is an essential characteristic of the Italian system, and the reliefs of the several works are by it restricted within certain limits, as it is necessary so to determine the levels of the opposite flanks that the fire along their superior slopes shall defend the whole of the intervening curtain; but there are other modes of using musketry as well as artillery fire in the defence of the ditches, and on these were founded other systems of Fortification.

The first Italian writer on Fortification was Tartaglia, whose work was published in 1546; but the really first writer on the science was Albrecht Dürer, a great painter, sculptor, and engraver, and a civil and military architect, whose work is dated 1527, being published one year before his death. This remarkable man founded his system on the old circular tower-forts C, fig. 62, with which the dead space is much less than with square tower-forts, and, enlarging the towers to an enormous extent, he adopted the name "Bastei," or in the plural "Basteien," for his new work. As attention was at this early period more directed to cannon than to the rude musket as an instrument of defence, it was natural that the latter should be less considered in these arrangements than the former. Dürer based his systems on the principle that the defences of basteien or other works which depend only on the cannon placed on their terrepleins may be effective whilst the enemy is at a distance, but cannot be so when, under cover of his epaulements, he has reached the ditch; and leaving therefore to the cannon on the terreplein the task of firing upon the enemy's troops and batteries at a distance, he placed cannon and musketry either in vaulted galleries running along the base of the escarp, or in caponnières, also vaulted or casemated works, built across or transversely to the ditch. The great circular bastei of his third and most improved system was no less than 130 yards in diameter, with an escarp 120 feet high, a ditch in front 100 feet wide, and a massive envelope, about 80 feet thick and 100 feet high, formed of earth with thick masonry revêtements both in front and in rear, as a mask between the main work and the counterscarp. Such gigantic proportions as these have led many to consider Dürer as little more than a speculative writer, but this would be an unjust estimate of his real merits. Reducing his works to more reasonable dimensions, they would, with proper modifications, have become practicable, and they have afforded many useful hints to the scientific engineer. The defects of the circular form were compensated by the grazing fire of the caponnières in his system, and the main work was retained in an effective state by the cover afforded to it by the envelope. We shall have occasion to refer again to Dürer, but in the mean time it may be said that whilst the Italians are properly considered the originators of bastioned systems with an earthen parapet over which the musketry fire is directed, Dürer has an undoubted claim to be considered the author of the systems of Fortification in which casemated defence in the main works and in the caponnières becomes the essential characteristic—a system which has proved more fertile in results in modern times than the bastioned system.

Systems of Permanent Fortification,

1. *Vauban's First System.*

Plate. III. Before commencing to draw a plan of Fortification, it is usual to determine the polygon on which to describe it. In Plate III., fig. 1, the angle taken is that of an octagon, and the length of the side is 360 yards. In constructing a fortification, a figure is determined on, as near a regular polygon as possible, within which the enceinte or chain of main works is to be contained. The enceinte or body of the place consists of as many bastions, connected with curtains, as there are sides to the figure, and each of these is made about 400 yards.

The *Principal Line* or *Outline* denotes the line by which the figure of the work is defined. This line is supposed to pass along the cordon of the escarp, and is that from which all the other parts of the work are set off.

The *Exterior Side*, or side of the polygon above mentioned as equal to 360 yards, is that upon which the Front of the Fortification is described, and it extends from the flanked angle of one bastion to the corresponding flanked angle of the next, as AB. These lines are bisected, and a perpendicular CD is drawn from the point of bisection towards the place, its length being proportional to the length of the exterior side and adjacent angle of the polygon,—that is, one-sixth for the hexagon and all figures of a greater number of sides, one-seventh for the pentagon, and one-eighth for the square.

The *Lines of Defence*, AEG, BFH, are drawn from the extremities of the exterior sides through the point D, and produced to an indefinite length; and upon the lines so drawn are set off two-sevenths of the exterior sides, equal to $102\frac{6}{7}$ yards, which mark the points for the shoulders of the bastions, E and F. The distance between these points is then laid along the continuation of each line of defence, viz., from E to G and from F to H, and the line connecting G and H is the curtain GH, from the extremities of which lines are drawn to the points marked off for the shoulders of the bastions, and these form the flanks. In this manner is drawn a Front of Fortification, and this being repeated upon each side of the polygon, completes the works of the enceinte, or body of the place.

Vauban divided his first system into three classes, namely, the little, the mean or intermediate, and the great. The first he used for small forts of four or five sides, citadels, horn-works, and crown-works, making the exterior side from 120 to 240 yards, the perpendicular equal in the square to one-eighth, and in the pentagon to one-seventh, and the faces of the bastions in each equal to two-sevenths, of the exterior side. In the mean or intermediate, which is adapted for all sizes of towns, the exterior side varies from 250 to 360 yards, the perpendicular is one-sixth, and the faces of the bastions are two-sevenths. In the great the exterior side varies from 360 to 520 yards. This was never adopted for all the sides of a place, but only in the case of one which happened to be near a river or a marsh, when the distances of the bastions should be so regulated that they may not be out of musketry range from one another. When the curtain becomes unavoidably too long, this defect is in part remedied by erecting on it a flat bastion, which is not so high as the rest of the works.

Ground which will admit of being regularly fortified throughout is seldom met with; nevertheless, the rules of regular fortification must be observed as nearly as possible, These are—that the flanked angles should not be less than 60°, that the lines of defence should not exceed musketry range, and that the sides should be lengthened or shortened so as to obtain a well proportioned front upon each. After an irregular place has been reduced to as regular a figure as possible, lines are drawn parallel to the sides of the figure at the distance of about 50 yards from the houses, in order to give sufficient space for the rampart; and these lines form the interior polygon, which may be fortified outwards, by setting off the demigorges of the bastions, and raising their flanks at angles of 100° with the curtain. Or the exterior side may be formed and fortified inwards by drawing a line parallel to each of the interior sides; and when the angle is that of a polygon of more than five sides, the distance from the exterior to the interior sides should not be less than 100 yards. If a side extend from 360 to 520 yards, the perpendicular should be diminished to about 50 yards, and the faces of the bastions be made from 100 to 120 yards. All these dimensions should, however, be now much increased, and placed in relation to the range of the modern rifled small arm.

The *Ditch* or *Fosse* is an excavation of from 15 to 30 feet in depth, and from 30 to 50 yards in breadth, surrounding the rampart on the exterior side; the earth dug out of it serves for the rampart and parapet. The side of the ditch next the place is called the *escarp*, the side next the country is called the *counterscarp*, and is made circular opposite the salient angles of the works. In the figure arcs are described with a radius of 30 yards, opposite the salient angles of the bastions, tangents to which are drawn upon the shoulders of the neighboring bastions, and thus the width of the ditch is fixed. The general dimensions of a ditch should be such that its excavation, or deblai, would produce sufficient earth, or remblai, for the formation of the works. The breadth varies from 30 to 50 yards, in order that, in passing across it to the assault, the enemy may, for a considerable time, be exposed to the fire of the works; and its depth must be such as to render difficult the escalade of the parapet, as well as to prevent the besiegers at the crest of the glacis from being able to see the lower part of the revetment of the escarp. The line of the counterscarp is drawn from the rounding at the salient angles of the bastions upon the shoulders of the bastions next adjoining, in order that the whole of the ditch may be defended by the fire of the flanks of the bastions. Ditches are of three kinds,—wet, dry, and such as may be rendered either wet or dry. The wet ditch is effectual against surprises or sudden assaults, excepting during hard frost, for it may be passed when frozen, as in the attempt to surprise Bergen-op-Zoom in the year 1814; but the number of bridges of communication, which require continual repair, and the difficulty of making sorties, render a wet ditch extremely inconvenient. A dry ditch, which is capable of containing works for its own defence, and by means of which communications round the works may more easily be maintained, is therefore preferable; but the third kind, which unites the advantages of the other two, is to be preferred to either. It is only in particular situations, however, that such a ditch is practicable.

The *Tenaille*, in the form given to it by Vauban, does not appear in the works of earlier engineers, but it seems to be naturally derived from the trace of Rimpler (1673), in which the *middle flank* is analogous in function to the tenaille, and occupies its position. It is a work placed in front of the curtain, and is thus formed:—its side faces are upon the lines of defence, and commence at points 11 yards distant from the shoulders of the bastion; its front face is 28 yards from and parallel to the curtain; its gorge is parallel to and 17 yards from the faces; its ends are parallel to the flanks of the bastions. The relief or height of the tenaille is determined by that of the neighboring flanks, and it has a parapet of 7½ feet in height and from 12 to 15 feet in thickness. The use of the tenaille is to cover the postern gate, which is often made in the curtain or flank; in dry ditches it protects the troops formed behind it for the defence of the ditch; in wet ditches it covers the boats collected for the same purpose. It adds materially to the defence, as its fire, from being more horizontal and nearer to the bottom of the ditch, is of course very effective. It fires into the ravelin, and acts as a partial traverse to the escarps of the curtain and the flanks.

The *Ravelin* or *Demilune* was originally designed to cover the entrance to the fortress, but it soon developed into a most important work of defence, appearing as such in some early Italian Traces. Speckle, the great German engineer, who fortified Schlottstadt, Hagenau, Ulm, Colmar, Basel, and Strasburg, was, however, the first who recognized fully its importance, and laid down the rule that "great ravelins materially augment the defensive power of a bastioned system." Constructed upon this principle, the ravelins of Speckle were even larger than the ravelins of Cormontaigne's system, and covered nearly the whole of the bastions, their faces being directed on the salients of the

bastions and their capitals, extending about 150 yards in advance of the exterior side of the polygon. Speckle was a man of science, having studied mathematics and military engineering in his youth, and perfected his knowledge by visiting and inspecting the most remarkable Italian fortifications existing in his time. The Ravelin is a work constructed opposite the curtain, of two faces meeting in an outward or salient angle, with two demigorges formed by the counterscarp. Its use is to cover the curtain, the gates, and the flanks of the bastion. The Ravelin is constructed as follows. At 11 yards from the shoulder along the faces of the bastion, points are set off; an arc is described from the angle of the flank upon the perpendicular produced, with a radius of 160 yards; from this intersection lines are drawn towards the points set off, but not further than the lines of the counterscarp; at the intersection of the lines of the counterscarp or re-entering angle 6 yards are set off on the capital or line bisecting its angle, whence lines are drawn parallel to the lines of defence till they meet those of the counterscarp. Stairs, called *pas-de-souris*, are constructed here in order to facilitate the entrance into the ravelin from the ditch. The ditch in the ravelin, which is 24 yards in breadth, is made circular at the salient angle, and drawn parallel to the faces till it joins the main ditch.

The *Covered-way* was first described by Tartaglia in 1554, so that it must have been used at a very early epoch of Italian Fortification. Some of the first bastioned fortresses were, however, without this highly important work; and it is recorded that at the siege of Vienna by the Turks, the garrison having made a sortie, some companies were pursued by the Turks up to the counterscarp, and forced over it into the ditch. The necessity of being able to assemble *under cover* from the enemy's fire the troops intended for a sortie, and to afford them when repulsed a place for reforming and checking the enemy's progress, and thus insuring an orderly retreat into the body of the place, soon became apparent, and a Covered-way was supplied to works originally constructed without one. It is a space of 10 yards in breadth, extending all round the work between the edge of the counterscarp of the ditch and the parapet which covers it; this parapet is from 7 to 9 feet in height, and has a banquette for musketry. The superior part of this parapet forms a gentle slope towards the country, which terminates at the distance of from 40 to 70 yards; and this slope is called the *Glacis*. The Covered-way serves for drawing up troops in order to make sorties, and costs less than any other part of the works in proportion to the difficulty of taking it. In its salient and re-entering angles are open spaces called *Places of arms*.

The *Salient Places of arms* are the open spaces between the circular parts of the counterscarp and the prolongation to intersection of the branches of the covered-way. The *Re-entering Places of arms* are constructed with two faces, forming a salient angle of 100° with the covered-way. The demigorges of the re-entering places of arms are generally from 24 to 30 yards; but when they are intended to contain a redoubt or intrenchment, they are from 40 to 48 yards. The Re-entering Places of arms are meant to flank the branches of the covered-way, and to contain the troops for its defence. The Salient Places of arms also serve for the assembly of troops for the defence of the covered-way.

Traverses are constructed across the covered-way, upon the prolongation of the sides of the ravelins and bastions, perpendicular to the line of the counterscarp; they are from 18 to 20 feet thick, and serve to cover the troops from the enfilading fire of the enemy. Other traverses are constructed between these, so placed that the distances between them should not exceed 40 yards. Passages 10 or 12 feet wide, which are formed by cutting into the parapet of the covered-way round the ends of the traverses, afford thorough communication; the openings are closed when necessary by gates. In the more improved systems of Cormontaigne and others, these openings are constructed in such a manner that each can be defended by the fire from the traverse in rear of it.

The *Glacis*, as already stated, forms a gentle slope from the parapet of the covered-way towards the country, and varies from 40 to 70 yards in length. Its parapet cannot be ruined by the fire of the enemy; it covers the revetment of the body of the place; and being an inclined plane, it can be easily seen and defended from any part of the works.

The *Rampart* is an embankment of earth, and is the part of the works next to the town which it surrounds. It must be broad enough to carry the parapet and to provide sufficient space behind it for working the guns, and for the free passage of the defenders. The *Ditch* is immediately in front of the rampart, which is sustained by a revetment-wall of masonry or brickwork, called the escarp, strengthened by interior buttresses, called counterforts, placed at intervals regulated by the height of the wall and their own thickness. The Rampart is divided into the *terreplein*, the *banquette*, the *parapet*, and the *escarp*. See Plate III., fig. 4.

The *Revetment* or face of masonry around the work on both sides of the ditch is intended to prevent the earth above from falling into the ditch. To ascertain the proper thickness of masonry for revetments has always been a matter of considerable trouble and difficulty. General Sir Charles Pasley of the Royal Engineers has given the following rules. (1) For full-scarped revetments without berms, and for demi-revetments having berms equal to one-fourth the height of the masonry, the thickness of the wall should be seventeen-sixtieths, and the length of the counterforts or buttresses one-fifth of their height. (2) For demi-revetments without berms, the mean thickness of the wall should be three-tenths, and the length of the counterfort one-fifth of the height. (3) For counterscarp revetments, having only to retain simple terrepleins, the mean thickness should be one-fourth, and the counterfort one-sixth of the height. In all these cases General Pasley supposes the revetment to be countersloped, that is, to have the exterior slope in a vertical plane, and the interior face inclined, so that the base of the wall may be broader than its top by one-fifth of its height; and he also supposes the counterforts to be rectangular, and the intervals between their centres to be equal to four times their width. (4) He recommends that the foundations be made deeper in rear than in front,—that the courses of masonry form an angle with the horizon of about 10° till within a foot from the exterior, where they should be horizontal, to prevent the rain from penetrating,—and that the interior face of the wall should be of irregular form. The lateral pressure of the earth against the revetments may be diminished by building arches in one or two tiers between the counterforts.

The *Cordon* is a round projection of stone, about a foot in diameter, near the top of the revetment wall, which serves to throw the drip of rain off the face of the masonry. It is also a considerable obstacle to besiegers, as it prevents their ladders for escalade being placed against the escarp.

The *profile* or *section* of Vauban's first system is given in Plate III., fig. 4, in order to illustrate the relative relief or height of the respective works, and to show the command which each has over the work in its front. When the height of the rampart, including that of its parapet, is 20 feet, and that of the parapet of the covered-way is 9 feet above the plane of the site, then the rampart will have a command of 20 feet over the country, and 11 feet over the crest of the covered-way; and the latter, again, will have a command of 9 feet over the country. There are three sorts of command, namely, in front, in rear, and in enfilade. That in front is when any eminence which commands the work directly faces it; that in rear when the eminence is behind the work; and that in enfilade when the eminence is on the prolongation of any line or work. The last, which is the most dangerous kind of command, is best remedied by raising the salient of works exposed to it (see fig. 23, p. 377), or by erecting traverses. In fig. 4 of Plate III. a line, called the line of site, and supposed to be the surface of the ground on which the fortification stands, is drawn, and perpendiculars are erected on it equal to the respective heights of the different parts of the works corresponding to the lines in the figure;—*a* showing the terreplein, *b* the banquette or step to enable the soldiers to fire over the parapet, *c* the parapet, *d* the revetment, *e* the escarp, *f* the counterscarp, and so on.

2. *Vauban's Second and Third Systems.*

The principles of Vauban's First System having been thus explained, no great difficulty will be experienced in understanding the methods of other engineers who have constructed works varying but little in essentials from this system, the variations having arisen from difference of situation and local peculiarities rather than from other causes. In his other methods of construction, as, for example, in his second and third systems, Vauban himself merely modified, according to circumstances, the principles upon which his first is based. When this celebrated military engineer was called upon to repair or improve the fortresses of Landau, Breisach, etc., and found these places surrounded with strong walls strengthened by small towers at the angles, he did not destroy these defences, but constructed, nearly in the same proportions as in his first system, large counterguards or bastions in front of the towers which crowned the angles of the wall, just as the Italian Castriotto had done in 1584. And by this method an important object was attained; for, as in front of each tower, or rather tower-bastion, there ran a ditch which cut off all communication between it and the counterguard, so the enemy, even if they should have succeeded in establishing themselves in the counterguard, would still have another ditch to cross, and another wall to breach, before they could attempt to give the assault.

There is so little difference between the second and third systems of Vauban that a description of the former will enable the reader to appreciate the peculiarities of the latter. In the second system (Plate III., fig. 2), the interior side of the polygon, from the centre of one tower-bastion to that of the next, is supposed to be 240 yards, and at 24 yards from its extremities perpendiculars are erected equal to 36 yards for the flanks of the tower-bastions. A line is then drawn through the extremities of these perpendiculars, parallel to the interior side AB, till it meets the oblique radius of the polygon, or line drawn from the centre of the polygon bisecting its angle, and this being done on both sides of the angle forms the tower-bastion. The oblique radius is produced 78 yards, and lines of defence are drawn to the angle where the tower-bastion joins the curtain or line AB. On these lines of defence, the faces of the counterguard, or exterior bastion, are set off equal to 128 yards, and from the point forming the shoulder, flanks are directed to a point set off on the line AB, at the distance of 70 yards from its extremities. From the salient angles of the tower-bastions arcs are described with a radius of 14 yards for the breadth of the ditch, and tangents to these arcs are drawn parallel to the faces of the tower-bastion, but stopped where they would meet a line drawn from the salient angle of the tower-bastions, at the distance of 20 yards from the flanks.

The *tenaille* is the same as in the first system, excepting that at its ends it is carried down till it meets the lines of defence drawn between the flanked or salient angles of the tower-bastions. The *ditch* in front of the counterguards, or, in other words, the main ditch, is constructed in the same manner as in the first system. The *ravelin* is formed by setting off 90 yards from the re-entering angle of the counterscarp, and directing its faces to points set off on the counterguards, at the distance of 20 yards from the shoulders. A flank is formed by cutting off the corners of the ravelin at the distance of 14 yards on its demigorge, and 20 on its face; and this flank serves for the placing of guns in such a manner that their fire may be directed into the counterguard, or into the ditch before them, as occasion may require. Again, at the distance of 48 yards from the re-entering angle of the counterscarp, lines are drawn parallel to the faces of the ravelin for the *redoubt;* a ditch is formed in front of this, and parallel thereto, about 18 feet in breadth; and the redoubt thus constructed has a command of 4 feet over the parapet of the ravelin, as the tower-bastions have over the counterguards. The *covered-way* and *glacis* are formed as in the first system. It sometimes happens that redoubts are constructed in the re-entering places of arms; in which case their demigorges are made from 15 to 40 yards, and their faces set off at an angle of 100°, as before.

3. *Cormontaigne's System.*

The difference between the Systems of Vauban and Cormontaigne may easily be discovered by an examination of Plate III., fig. 3. Vauban makes the faces of his bastions two-sevenths of the exterior side, and Cormontaigne one-third. Vauban, in his first system, directs the faces of his ravelin to points upon the faces of the bastion distant 11 yards from the shoulders, and in his second and third systems, to points distant 20 yards; but Cormontaigne makes the capital of his ravelins about 120 yards, and directs the faces to points distant 30 yards from the shoulders; by which means the flanks are better covered, and the bastions and ravelins are enlarged. And this is an advantage; for he is thus enabled to construct a larger redoubt in his ravelin, the curtain and flank are also better covered, and, as the former is shorter, communications are more easily kept up between the bastions. Cormontaigne gives the same breadth to his covered-way as Vauban, but he arranges in a different manner the communication round the extremities of the traverses, as may be seen by inspecting the plate. By this zig-zag line of communication, which resembles the crémaillère trace adopted by Speckle in his covered-way, the passage round the extremity of one traverse may be defended by the fire of the other in its rear, or nearer to the body of the place, and the advance of assailants along the covered-way checked. As Speckle planned in 1589, or long before the invention of ricochet fire by Vauban had rendered traverses an essential element in fortification, his object was not the same as that of Cormontaigne, but simply to ensure a more perfect flanking defence of the branches of the covered-way than that afforded by the places of arms of his systems. The ditches are, as shown in fig. 3 of Plate III., on different levels—the main ditch being about 23 feet deep, and the ditch of the redoubt of the ravelin only 7 feet, so that from this latter ditch there is a fall of 16 feet to the main ditch, rendering it impossible to attack the ravelin by its gorge without the aid of ladders. An examination of the several figures which represent Vauban's and Cormontaigne's systems, as also the outworks of fig. 3, Plate IV., will at once render evident the vital defect of the ordinary arrangements of outworks—that they expose through the openings of their ditches the escarp of the body of the place, or of the work on which their faces or branches are directed, to be breached. In the System of Cormontaigne, as well as in the Modern System next to be considered, the increased projection of the ravelins, by throwing the intervening bastion into a deeply re-entering position, secures it from attack by approaches until the salients of the ravelins have been taken; but this great advantage is diminished by the power of breaching the bastion from the glacis through the opening afforded by the ravelin ditch. For the purpose of covering the communication to the re-entering place of arms, a *demi-caponnière*, or work composed of a parapet and glacis, was thrown across the ditch of the ravelin, as shown in the figure of the modern system (Plate IV., fig. 2). This work afforded cover also to troops assembling preparatory to a sortie upon the enemy when making the passage of the ditch, but, from the depth of the ravelin ditch, it was insufficient to mask the revetment of the bastion behind it. It will presently be shown how this object was afterwards effected; and it may be said that without any material change in system, Cormontaigne's variations from Vauban's trace are unquestionable improvements.

4. *The Modern System.*

Plate IV.

The Modern System, which is shown in Plate IV., fig. 2, varies little from Cormontaigne's. Its perpendicular is one-sixth of the exterior side, and the faces of the bastions are one-third. The flanks are at right angles to the lines of defence, whereas in Vauban's System they form an angle of about 82°,—which is not so good, because, in the Modern System, the guns placed in the flanks can fire straight along the ditch without being moved or turned on their platforms. The ravelin is formed by setting off points 34 yards from the shoulder along the face of each bastion; a line joining these points is the base of an equilateral triangle, the vertex of which, opposite the centre of the curtain, forms the salient angle of the ravelin. The redoubt of the ravelin is formed by drawing its faces parallel to those of the ravelin from the shoulder of the parapet of the bastion; and it has flanks with a ditch about 20 yards in breadth. The *cavalier* in the bastion is drawn parallel to the faces of the bastion, at the distance of 48 yards from them. The ditch of the faces is 10 yards in width, but there is no ditch to the flanks. In bastions strengthened by a cavalier retrenchment, a coupure is formed perpendicularly across the faces of the bastion; the ditch of the coupure is 30 feet wide, and the counterscarp is traced from a point 36 yards from the shoulder of the bastion to meet the counterscarp of the ditch of the cavalier. This system originated in the school of military engineering instituted at Mézières in 1750, and was for some time called the system of the school of Mézières. It has, however, been much improved since; and the system which is now recognized as

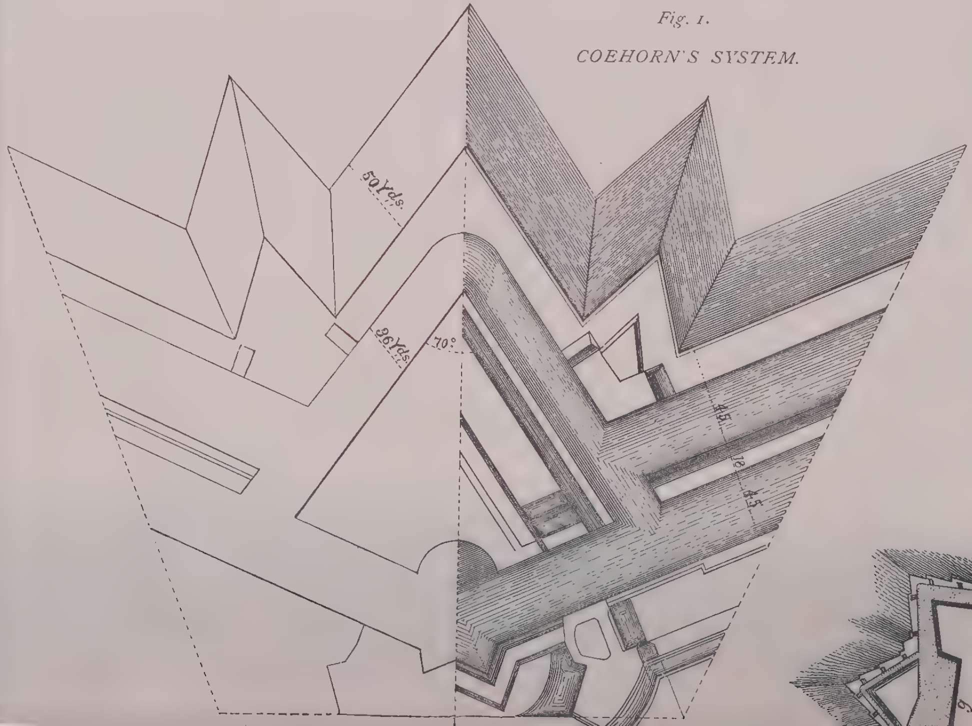
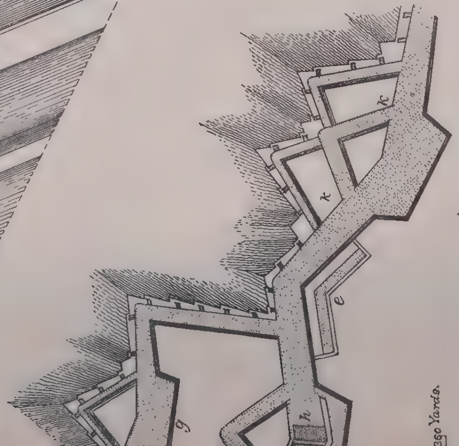
COEHORN'S SYSTEM.





eau, g-Hornwork, h-Caponnière, k-Tenaillon.

the "Modern System" is that of General Noizet. Referring, however, to fig. 2 of Plate IV., it will be seen that coupures have been introduced in the faces of the ravelin; and as the ditch of the ravelin in this system is less by 7 or 8 feet than the main ditch, there is a sufficient fall between the two to check the enemy in his passage to the latter, whilst the demi-caponnière is raised so much higher, and therefore begins to mask more effectually the revetment of the bastion. In General Noizet's system this demi-caponnière is formed into an elevated mask, which tends to secure the revetment from the breaching effect of the fire from the enemy's battery on the crest of the ravelin glacis. This is shown in fig. 63; and the system modified from the former modern system in this respect, as well as in other arrangements, is now the normal bastioned system of the French schools. In General Noizet's arrangement the flanks are not made perpendicular to the lines of defence, but, as in Vauban's first system, form angles of about 80° with them. In the citadel of Ghent, which is a beautiful example of this system, but with still further modifications, the retrenchment of the bastion is so formed as to take advantage of this construction; and the flanks, being casemated and pierced in both directions, become on one side the flanks of the retrenchment, whilst on the other they are the ordinary flanks of the bastion, thus giving a much longer curtain to the retrenchment, which occupies the whole gorge of the bastion, than in the form exhibited in fig. 2 of Plate IV.

5. *Outworks.*

Plate IV., fig. 3, shows several kinds of Outworks, as a horn-work *g*, tenaillons *k* and *k*, a bonnette *d*, lunettes *a* and *d*, an entrenched bastion *e*, a batardeau *f*, and a caponnière *h*. These, and other works of a similar description, are constructed for the purpose of occupying ground which might otherwise be of service to the besiegers, or, as in the caponnière, to cover communications; but their application must of course depend upon localities, and the judgment of the engineer must therefore determine in each particular case which are the best to adopt.

POLYGONAL OR GERMAN SYSTEM.

The Systems of Fortification of which mention has been made were devised to meet the attack of horizontal fire, but henceforward the efforts of the engineer must be directed to devise methods of protection against curved and indirect fire of greatly increased range and power. It is true that the efforts of the later engineers have been in this direction, but the recent introduction of rifled guns and the still more recent development of indirect fire have rendered a recourse to very different measures absolutely necessary.

Before entering upon the consideration of these measures, it may be well to point out that a rigid adherence to the theory of defilade, which is based on the erroneous supposition that the path of projectiles is in a straight line, and, as a consequence, that artillery can only strike that which it sees, has contributed more than anything else to detain the art of defence behind the art of attack; indeed engineers of great weight were wont to maintain that, if the cordon of the escarp were in the plane passing through the crest of the glacis, the escarp was perfectly covered from artillery fire. Cormontaigne and Montalembert have fallen into this error, and so in more recent times have Choumara and later writers upon the Polygonal System.

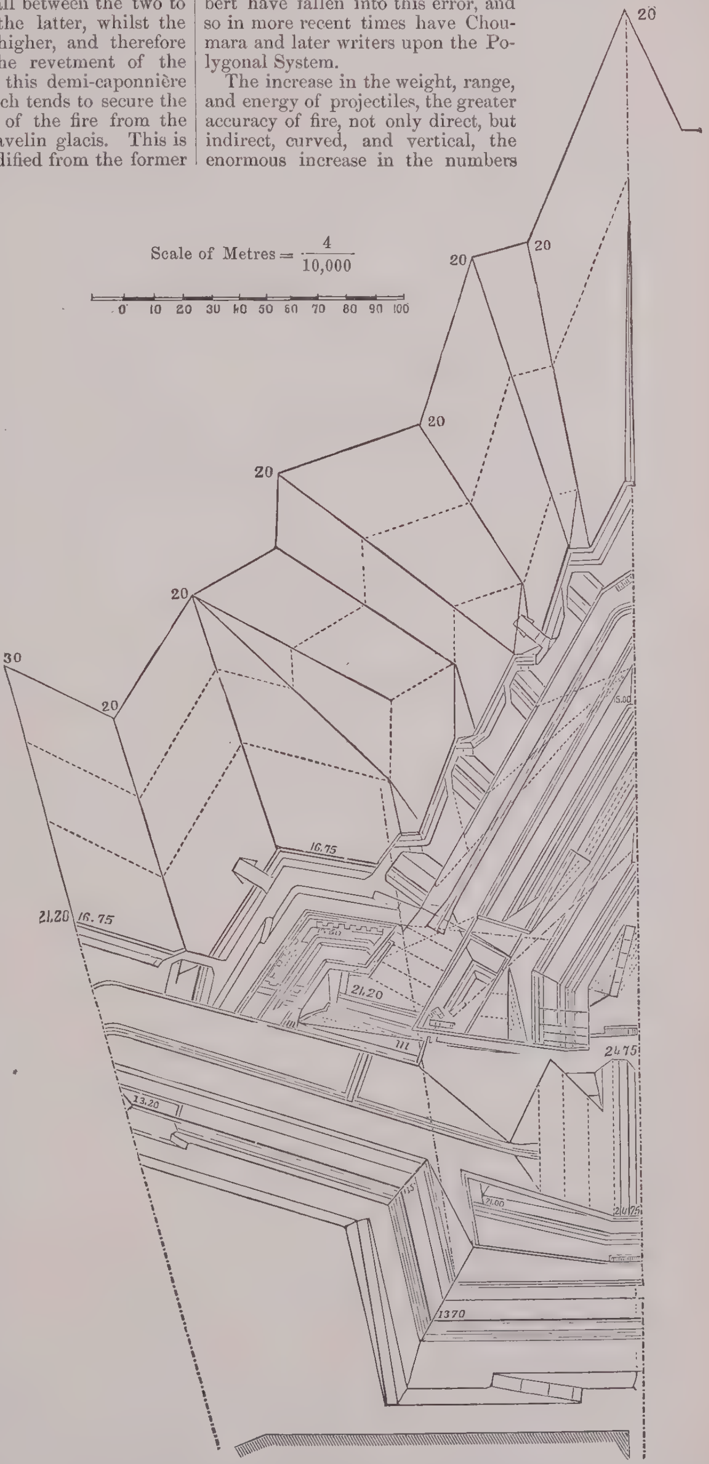


FIG. 63.—Half-Front of the Modern System.

The increase in the weight, range, and energy of projectiles, the greater accuracy of fire, not only direct, but indirect, curved, and vertical, the enormous increase in the numbers of armies, and the wonderful mobility afforded to them by the development of railroads and steam vessels, by the subordination of steam, machinery, telegraphy, and other scientific applications of modern life, to military purposes, have rendered necessary fortresses of an enlarged and of a more expensive nature, and have led to the adoption of a system of defence more simple, and based upon broader principles.

N. B.—The penetration of the siege howitzers is comparatively small. The lowest effective velocities against revetments are considered to be from 450 to 500 feet a second.

The Bastioned Trace designed to afford from uncovered flanks a complete defence to the escarp of the body of the place can accomplish this end no longer, since these flanks can now be destroyed by the fire of distant artillery, and the faces of the bastions themselves can be ricochetted from an equal distance.

Moreover, this trace, in which the relations between the length of the front, the depth of the ditches, and the command of the enceinte are obligatory, is difficult of application, and weak in its direct artillery defence, inasmuch as a portion of the rampart which should be available for the defence is withdrawn for the service of the flanks and curtains.

In the Polygonal Trace,—which requires no inter-relation between the length of the front, the depth of the ditches, and the command of the body of the place, in which the exterior sides may at pleasure be longer or shorter within the limits of musketry fire, and the line of parapet may be independent of the line of ditch,—these defects disappear, and its application to every variety of ground is more easy and more economical. As, too, the flanks are entirely protected from distant fire, and the faces are not exposed, or are far less exposed, to ricochet than in the angular traces, the polygonal trace offers greater facilities for the employment of artillery as the principal arm of defence, while it has yet another advantage, viz., that its communications are far more simple.

The main difference between the Polygonal and the Bastioned Systems lies in the arrangements for the defence of the ditches. In the latter it is provided by the flanks of the bastions, in the former by caponnières, powerful casemated works, constructed across the ditches. In the flank of the bastion the guns are exposed, and limited in number by the length of the flank; if the flank be lengthened, the face of the bastion must be shortened, thereby diminishing the direct artillery defence of the bastion, or the flanked angle of the bastion must be diminished, rendering the faces—already too liable—still more liable to enfilade. Moreover, a second or lower tier of casemated guns cannot be added to the flank of the bastion without the suppression of the tenaille and consequent exposure of the curtain; whereas the caponnière may be increased in length to any reasonable extent, and may be in two tiers. Again, in the bastion the flank is enfiladed by direct fire on the adjoining face, and is taken in reverse by the enfilade of that face, and by the direct fire against the opposite face and flank. Lastly, in the Polygonal System a direct fire can be given upon the capital of the angle, while in the Bastioned System this capital is undefended.

The advantage of this system in direct artillery defence appears to be 100 per cent.[1] Brialmont—no mean authority—states it at from 25 to 60 per cent., or even 100 per cent., if the artillery of the outworks is left out of calculation. In a comparison of the fortress of Posen, which is a faulty application of the polygonal system, with an equally strong fortress on the bastioned system, it has been calculated that the siege park of a besieging army would require 20 per cent. more guns for the attack of the former; and the writer goes on to state that more siege materials, a greater development of batteries, a greater number of troops, and a larger park are necessary for the attack of the polygonal as compared with the bastioned system.

Unquestionably, long exterior sides are advantageous for fortresses; and admirably, as has been shown, as the polygonal trace is adapted for fortresses, it is equally well adapted for detached forts, which are often so small that the bastioned trace is inapplicable to them.

Plate V.

The most complete application of this System to a great fortress may be seen in the enceinte of the new fortress at Antwerp, one front of which is shown in Plate V.

In this enceinte the main ditch is wet and wide, and flanked by a powerful central self-flanking caponnière; the flanks are retired and protected by orillons, and the curtain between the latter is broken into two half curtains, separated by a defensible barrack, which forms a retrenched cavalier. The central caponnière is separated from this curtain by a ditch; it is, moreover, covered by a counterguard of two branches, revetted with a loopholed counterscarp gallery from which the countermines diverge; this is further covered by a ravelin of two branches, terminating at the salient in a powerful reverse casemated battery; the ditches of the ravelin are flanked by low casemated batteries. The exterior side is 1100 yards long, the perpendiculars from the centre of this side marking the saliency of the caponnière and the retirement of the centre of the curtain are 104 yards and 71 yards long respectively. The curtain is 250 yards long; the flanks, which are not straight, are formed of two sides, 34 yards and 12 yards long. The flanks of the caponnières are 27 yards long. The salients of the counterguard and ravelin are 190 yards and 295 yards in advance of the exterior side, and the branches of the latter are directed upon points on the exterior line 245 yards on each side of its centre. The front of the defensible barrack is covered by the central caponnière, and the flanks are 84 yards long, forming angles of 100° with the front. The main ditch is 88 yards wide at the salients, and 55 yards wide in front of the orillons; the ditch of the ravelin is 66 yards wide at the salient, and 55 yards wide at the low casemated batteries of its flanks. The ditches are unrevetted, with slopes of two-thirds, except at the head of the central caponnière and in front of the curtain and flanks; the depth of water in them is 10 feet, and its surface is six feet below the plane of site; the berms of the enceinte and of the ravelin are 16 feet and 6 feet wide respectively. The command over the country is, in the body of the place, 32 feet at the salients, falling $1\frac{1}{2}$ feet to flanks and curtains, in the ravelin 15 feet, in the counterguard 21 feet designed that the outworks may not obstruct the fire of the body of the place; in the cavaliers of the salients the command rises to 41 feet. The parapets are slight, not more than 27 feet thick, but they have very wide terrepleins, and are provided with hollow traverses and large bonnettes. The ramps leading to the terrepleins are unusually wide. The guns are either on carriages firing over a 5-feet parapet, or on siege carriages firing from raised gun banks. The armament is heavy, especially in the central caponnières and flanks; in the former, 22 guns on each face, viz., 16 in casemates and 6 in open battery above, in the latter, 14 guns in two tiers. The ravelin has in addition to the guns on its faces 8 casemated guns in its reverse battery of the salient, and 12 casemated guns in its two low batteries; and provision is made for armoring the embrasures of these. The covered-way is 22 yards wide in front of the body of the place, and from 9 yards to 15 yards wide in front of the ravelin. The communications with the country are wide and ample, two through each front; they are also level, very direct, and convenient for sorties.

Epitomized as this description has necessarily been, it will be seen that advantage has been taken very skilfully of a low site and wet ditch, which while offering serious obstacles to the enemy impede as little as possible the offensive operations of the defenders. For the effective defence of the fortress, however, a strong and well-handled garrison, prompt to assume offensive measures, and a large armament are necessary.

---

[1] The German engineer Rimpler, writing in 1673, says that, not being agreed with respect to principles, engineers have disputed about insignificant details, while they have neglected two most important conditions, protection for the garrison from the besiegers' fire, and the concentration of a more powerful fire upon the besiegers.

Plan.

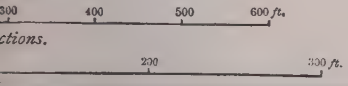

Plate VI. The city of Antwerp, Plate VI., lies upon the east bank of the Scheldt, and was originally closely girt by works of the bastioned trace, of which the last remnant, viz., the old citadel, which joined the new enceinte to the river on the south-west, has recently been removed. This enceinte consists of 11 fronts of polygonal trace in two lines, of which the 6 on the south and east line are about 2300 yards, and the 5 on the north line are about 1800 yards from the town, and are closed upon the river to the north by the new citadel, a work of considerable size and of the polygonal trace also. The fronts are about 1100 yards long, but the two lines join in rather an acute angle; and to compensate for the weakness of the enceinte at this angle, an advanced ravelin has been constructed on either side which prevents the lines from being enfiladed. The length of the enceinte is about 7 miles; but as this line of defence would not keep an enemy beyond bombarding range from the town, a line of 8 detached forts has been constructed about 4000 yards in advance of the enceinte.[1] These forts, also of the polygonal trace, are placed about 2200 yards apart; they close on the river on their right, and, extending over a circle of about 10 miles, rest upon an inundation on their left. Both fronts and forts are very strong, and form a great intrenched camp of about 17,000 square acres in extent. The forts are of the same trace, have wet ditches about 50 yards broad, unrevetted scarps, and bomb-proof accommodation for 1400 men in each; so that to fully garrison the enceinte and the forts about 25,000 men are required. On the west side the river runs in a deep re-entering angle towards the city, and four forts about 2200 yards apart close the space between its bends, and form a very strong defence, placing the city upon this side out of reach of the assailant's fire.

In England the polygonal trace has of late Plate VII. years been habitually adopted as the most suitable for general purposes, but it has not hitherto been found necessary to have recourse to a regular and continuous system of fortification, the insular position of the country, and its predominating strength at sea, calling merely for the fortification of the principal dockyards and military ports, and for the defence of the more important and more exposed harbors. The defence of the military ports is partly on the water and partly on the land, and has been so arranged in the more important ports that they form large naval and military intrenched camps. See Plate VII.

As with modern artillery bombardment is practicable at distances of from four to five miles, the works of defence have been disposed with a view of keeping an enemy at not less than that distance from the dockyards.

Upon the sea fronts the works consist generally of isolated forts, placed, according to the width of the channels, at intervals of 1500 to 2500 yards; these forts, being exposed to the very heavy rifled guns which form the armament of the largest iron-clads of the present time, are protected with shields or walls of iron upon their sea fronts, and when they stand alone in advance of the channel are constructed with a continuous iron wall. The various modes in which the iron composing their armor is disposed will be discussed in a future paragraph. The power of heavy rifled guns is shown in accompanying table.

Upon the land fronts the forts are ordinarily placed at intervals of about 2000 yards, though these intervals vary according to the nature of the ground. Where the ground is uneven they are smaller, but where the ground is level 2000 yards should be the least interval, and the forts should be of considerable size; beyond this distance the movement of troops becomes indistinct, and the support afforded by one fort to another is lessened, especially at night and in thick weather. A strong reason for constructing large rather than small forts is that at night or in thick weather offensive measures may often be resorted to with the happiest results. But the garrison of a small fort can never be in a position to undertake such measures; it must always restrict itself to a passive defence, whereas the garrison of a large fort will be able to act offensively, will be in better heart, and better commanded. Brialmont, speaking of small detached forts, says that one of the inconveniences of works of mutual defence is to require a great number of commandants, while in the best armies the men fit to command a fortified place are few.

The trace of these forts is very simple. It ordinarily consists of five sides, the longest of which fronts the enemy; the flank defence of the ditches is provided by three caponnières, one in the middle and one at each extremity of the front face. The ditches are deep, with good scarps, and the defensive power is increased by a keep, which is separated from the fort by a ditch. There is sufficient bombproof cover for the garrison and munitions of war, and the faces are well traversed, while special arrangements are made for the service of the ammunition. The general arrangements may be readily perceived by a reference to the accompanying plan (fig. 64) and sections (figs. 65, 66).

Between the land fronts and the sea fronts the circle of defence is completed by coast batteries. These batteries, which are constructed of earth, concrete, or granite, are of various types, with embrasures protected by iron shields when near the sea-level, but when upon heights not below 100 feet above the sea level, with unbroken parapets, the gun firing over a height of 4 feet 3 inches, the cover for the gun detachment being provided by a "sunken way," 3 feet 9 inches wide and 2 feet 10 inches deep, between the platform and the parapet. Over this sunken way, which is provided with rails, "a loading stage" travels, upon which the charge is brought immediately under the muzzle of the gun.

---

[1] A second and still more advanced line of detached forts has been commenced considerably in front of this line.

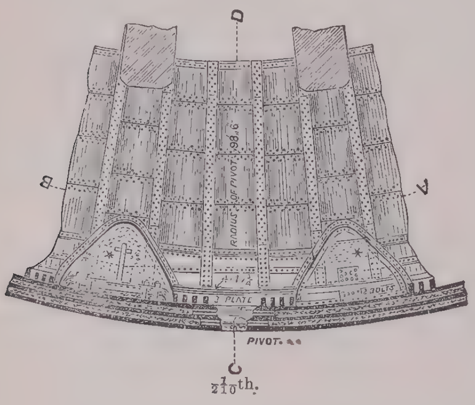

FIG. 64.—Plan of Sea Fort, with continuous Iron Wall. The piers marked (*) are filled with concrete.

Though at this and heights above it the "sunken way" affords fair protection to the gun detachment, except at the period of loading and pointing, yet, at these periods, the men employed upon these services are highly exposed, and at all times the gun itself stands high above the parapet, and offers a good mark to an enemy's ship. Some form of "*disappearing carriage*," upon which the gun is raised above the crest of the parapet at the moment of delivering its fire, and falls by the force of its recoil to a safe position for loading below the parapet, has long been sought for by artillerists. Such a carriage was proposed by Corneille Redeichkeit in 1775 for the defence of the covered-way; but his system, which depended on cords and counterweights, was too cumbrous to move from place to place, and liable to be readily put out of order, and was abandoned. Other inventors endeavored to attain the same end by the use of eccentric trucks and axletrees so disposed that the gun was on the greater axis for firing, on the smaller for loading; but the difference between the heights of the gun in the two positions was so small that this idea was also abandoned. Two guns were next yoked together by ropes, so that one falling from the firing to the loading position raised the other from the loading to the firing position. General Chasseloup, who proposed this twin-gun system, was occupied thirteen years upon its consideration; and though a mode proposed by him, by which one gun recoiling down one inclined plane drew its twin gun up a similar adjoining inclined plane, was tried with some success at Milan, it does not appear to have been adopted elsewhere. The matter then rested until Moncrieff produced his counterweight carriage, in which the recoil, while carrying the gun and carriage under cover to the position for loading, raises and holds up, by means of elevators, a heavy counterweight; this counterweight, when the time for firing arrives, is set free, and by its descent raises the gun to the firing position over a parapet 9 feet high, behind which the gun detachment find ample cover—one man only being exposed while laying the gun. The main objection to this system is the great weight of the accessories, which for the 7-ton gun amount, including the carriage, to 20 tons. This has rendered it impossible to apply this counterweight system to guns larger than 7 tons, and even to these its application is very limited. This system is costly and difficult of execution as compared with barbette batteries, and as compared with casemated batteries is far less secure against plunging and vertical fire, which cannot fail to strike some one of its many parts, a slight injury to any of which must put the gun out of action. It is asserted by its partisans that it can be applied to hill sides, so that the presence of a battery of such guns shall be undiscernible by an enemy; but this assertion is not well founded. So much skilled labor is required for the construction of Moncrieff pits that they cannot be improvised, and when made they are by no means invisible. This system has been used to a limited extent by Great Britain, but has not been adopted in other countries. Brialmont, after describing it, says, "We should not be able to share the infatuation for the Moncrieff carriage which has been manufactured in England;" and, he adds, it is easy to foresee that the earth and rubbish which will be thrown into the battery during the combat will render the working of it slow, difficult and, in some cases, impossible. Certainly the carriage is complicated, and could not be repaired during action.

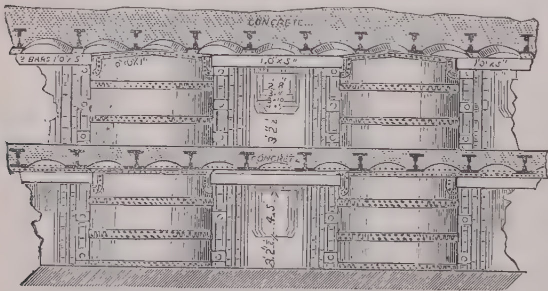

FIG. 65.—Section through AB of Fig. 64.

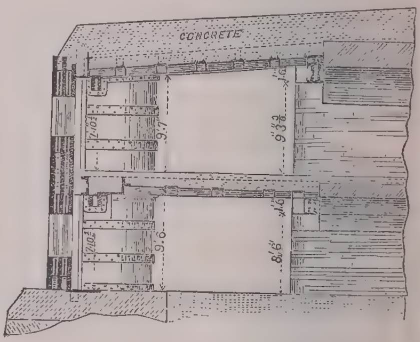

FIG. 66.—Section through CD of Fig. 64.

In earthen batteries protected with iron shields the parapets between the guns are comparatively weak, and, if they be increased in thickness so as to afford sufficient protection, they trench upon the interior space, and interfere with the service of the battery. The parapet, can, however, be strengthened by the insertion either of blocks of cement concrete or of plates of iron.

But as under given conditions the disposition and thickness of armor plates remain the same whatever be the nature of battery or fort in which the armoring is placed, the mode only in which the armoring is fixed being varied to suit the circumstances of each particular case, it will probably best meet the purpose of the present paper to give a short summary of the rise and progress of iron armor in its application to works of defence, illustrated by drawings of the most recent construction of each type of work.[1]

Attention first began to be directed to the application of iron to works of coast and harbor defence about the year 1860. At that time armor was being extensively applied to ships of war, and the manufacture of rifled guns had received considerable development, but iron had not been employed for the protection of defensive works, and nothing was known as to the best principles of construc-

---

[1] In this part of the subject the writer, in addition to other sources of information, has availed himself of a compilation prepared by Colonel Inglis, R. E., who has designed the principal part of the ironwork of the English sea defences, and who is the highest authority upon iron constructions employed for defensive purposes.

tion for iron defences or for the capability of this metal for resisting heavy blows. It was soon perceived that it was necessary to have recourse to experiment in respect to every detail of material and construction, and it was laid down as a fixed rule that no detail should be adopted until it had obtained the stamp of experience. Previous to the period of which we are treating an advance in this direction had been made in America in 1855, by the application of metal (lead) concrete to masonry embrasures (but this did not withstand the smooth-bore guns of that day), and at Portsmouth in 1859, by the construction of an embrasure shield, 14 inches thick, of rolled iron bars, which opposed a fair resistance to wrought iron shot from the 68-pounder smooth-bore gun, the most effective gun at that date. In 1860 the most important of the preliminary trials took place against an ordinary embrasure with an iron throat 8 inches thick. The guns used were the 40-pounder, 80-pounder, and 120-pounder (shunt) Armstrong rifled guns, and the 12-ton gun, with cast iron shot. The embrasure gave way, and it became apparent that the accuracy of rifled guns rendered splayed embrasures inadmissible in such positions. About this time, too, experiments with plates of various thicknesses in different positions—vertical, and inclined at angles varying from 10° to 60° with the horizon—showed amongst other results that a given mass of armor plates in a vertical position offered as much resistance as the same mass disposed over the same vertical height in an inclined position. In all these experiments the backings and fastenings occupied important positions. Targets were accordingly made with elastic backings, without elastic backings, and with compound backings of various kinds; but the general result of trials against these targets was to establish the advantage of elastic backings. The armor plates were fitted mechanically without bolts or rivets, were fastened with bolts, and were fastened with continuous riveting round their edges; the result of the experiments established the superiority of bolts as fastenings for armor plates. Many more experiments had, however, to be made before the proper form of bolt was settled; these were by no means the least interesting of the experiments made in working out this subject, but space does not avail to give the history of them here; and it may be sufficient to say that a bolt has been adopted about 3 inches in diameter in the shank, or rather less than the lesser diameter of the screw, which has a rounded thread (about 6 to the inch) and a shallow rounded cut; that the bolt holes are made one inch larger in diameter than the bolts; that the edges of the holes are coned, and that cupped washers receive the nut on the inner end, which is cup-shaped (as is the washer of the front of the bolt) as shown in Plate VIII.; and that various minor arrangements have been made for inducing gradual action, and so relieving suddenness of strain upon the bolt. Finally these bolts are made of special iron of a fibrous nature, and elongating from 35 to 45 per cent. under pressure.

Plate VIII.

The law of the resistance of armor plates received early investigation during the course of these experiments. Sir W. Fairbairn, supposing that the resistance of armor plates to the impact of a shot was analogous to the resistance of plates to a punch, deduced this general formula (C being made equal to 3,374,900):—

$$\text{Thickness of plate perforated} = \sqrt{\frac{\text{WO}^2}{\text{CR}}}\,.$$

Sir W. Armstrong endeavored to ascertain the resistance by the application of the dynamic theory of heat. Captain Noble, R.A., from many experiments, concluded that the penetration of steel shot is directly proportional to the work in the shot, whether a heavy shot with a low velocity or a light shot with a high velocity be employed; and that the resistance of armor to steel shot varied as the $\frac{3}{2}$ power of its thickness. But Captain English, R.E., who appears to have treated this subject most scientifically, considers that the energy absorbed by a plate in resisting a shot is made up of the energy expended in enlarging an indefinitely small hole through the plate, and of the energy absorbed in frictional resistance, and is equal to the cube of the diameter of the shot multiplied by a constant—a separate constant being required for each proportion to the diameter of the shot, of depth of indent in the one case, and thickness of plate in the other.

Having obtained a law which can be relied upon for thick armor plates (it is not, however, applicable to very thin plates), the mode in which the iron in an armor-plated wall should be disposed, *i.e.*, in one solid plate or in two or three thicknesses of plates, was shortly settled. A comparison of experiments against 7 inches of iron armor plate disposed in one, two, and three thicknesses gave resistances in the proportion of 100, 96, and 89. Further experiments against single and double plates of 5 inches showed that the double plate offered nearly three times the resistance of the single plate; and finally a comparison between a 15-inch plate and three 6-inch plates showed that though the solid plate offered slightly more resistance to a single blow it broke up sooner under repeated blows than did the three plates; but as, of course, there is a limit in manufacture to the mass of an armor plate, it is evident that the thicker the plate the more numerous will be the joints in a given area, and if the armor be in one thickness, all these joints are lines of weak resistance. The disposal of the joints, then, is a matter of first importance in designing iron structures, and in this respect the arrangement in several thicknesses, or the plate-upon-plate system, as it is called, offers the greatest advantage, for the plates can be so arranged that no joint goes through more than one-third the thickness; moreover, this system is more easy and more economical in construction, and can be strengthened with greater facility at any future time.

In order to put the conclusions arrived at to practical test, a shield for a casemate opening 12 feet long and 8 feet high was constructed of three 5-inch plates placed at intervals of 5 inches, the intervals being filled with iron concrete; the plates were whole, each covering the entire opening, and each was bolted to the plate next to it, the inner plate being bolted to the shield frame in rear; the front plate was secured by 10 bolts, the others by 8 bolts each; the total weight of the shield was 56 tons 8 cwt. It was struck with 16 shot from 25-ton, 18-ton, and 14·5-ton muzzle-loading rifled guns at 200 yards distance; the average energy of each blow was 5321 foot tons, and the aggregate 90,000 foot tons,—upwards of 1000 foot tons per foot superficial of the shield's face; but the shield was not driven out of shape, and its back or interior face was uninjured.

This experiment was so satisfactory in its results that henceforward there was no hesitation with respect to the broad principles of armor construction, and it only remained to adapt these principles to the different cases which presented themselves. These are sufficiently illustrated by the drawings in Plates VIII. and IX. The first is an open battery shield for an opening 9 feet wide and 7 feet high; the second is an ordinary casemate shield 12 feet wide and 9 feet high, and the third is a portion of an isolated sea fort with an exterior iron wall. The application of iron has facilitated improvements in the construction of the roofs of bomb-proof buildings, and the form of roof shown in the sea fort may serve as a model of construction of this kind. It is composed of arch plates of $\frac{3}{4}$-inch iron curved to a radius of 5 feet 6 inches, springing from iron girders 1 foot 9 inches deep and 1 foot 2 inches wide. The arch plates are covered with brick arches, which are again covered with 3 or 4 feet of Portland cement concrete. This roof is equal to a load of one-half ton per foot superficial, with a tensile strain upon the iron not exceeding 5 tons per square inch. Such a roof covered with 5 feet of earth was tested by vertical fire of 13-inch mortar shells at 1000 yards. The few rounds which struck it produced no effect, and after the 298th round practice was discontinued; but the earth was removed, and the bared concrete was struck by a shell, which only produced an indentation of 8 inches.

Plates VIII. and IX.

The cost of iron structures is, however, a drawback to their more general employment,—so much so that only wealthy nations can afford to erect them, and but in limited numbers. The cost of an open battery shield may be stated at £800, its weight 10 tons; of a casemated shield, £1800, its weight 40 tons; of an iron-walled fort, £5550 per gun, its weight 125 tons per gun.

It is, however, to be observed that, in special cases where the forts are constructed in very deep water, and where, consequently, the increase in the quantity of masonry in the substructure becomes very great for every additional foot of radius, an iron-walled fort, which admits of the guns being placed in a comparatively very small area, is the most economical method of construction, and that for constructive purposes a circle is the best form of such fort.

In all forts designed for very heavy guns special provision becomes necessary for the ammunition service of the guns. The cartridge and shell stores are kept separate, and are provided in the proportion of one of each for each gun, or each pair of guns. As a rule, these stores are securely placed in the basement under the gun they supply, the cartridges and projectiles being raised by mechanical appliances through "lifts" in the heart of the building to the rear of the gun. The ammunition stores are lighted by lamps placed in "light chambers," separated from the stores by thick plate glass; these "chambers" are entered from passages entirely distinct from the passages used for the service of the ammunition. The proper organization of the ammunition service is of the utmost importance for the efficiency of the fort; by it the labor of the gun detachment is lessened, and the rapid service of the gun facilitated. Each gun chamber is in speaking communication, by means of tubes, with its own ammunition stores, so that the men in the latter, though absolutely shut in below during action, still form part of their own gun detachment. Finally, the guns of the fort are collected into groups for purposes of command, and the guns of each group are directed from a "look-out" place constructed on the top of the fort, which is in speaking communication with each gun of the group.

It has been found that when armor is struck by a shot, lining of some kind is necessary to deaden the effect of vibration and sound, and to act as a target to receive, and protect the gun detachment from splinters thrown off from the interior. This lining should be flexible, so that it may be drawn close round the gun while it is being discharged, thereby keeping the smoke out of the gun chamber, may reduce the effect of blast and concussion, and may prevent splinters and balls entering through the port. No material has been found to answer so well as rope, and "mantlets," as such appliances are called, are now invariably made of this material. The only drawback to rope is its liability to catch fire, but this is entirely obviated by washing it with a saturated solution of chloride of calcium.

There are two other forms in which iron has been applied which should not be passed by without notice, viz., "curved-fronted shields" and "turrets." In the former the casemate is of the ordinary character, but the shield frame, which is constructed with a sharp curve of 13 feet or 14 feet internal radius, is more difficult to make, and more costly. Two ports of the usual dimensions are formed in the shield, and the gun is placed behind it upon a turn-table, on which racers are laid so that the gun will fire through a lateral arc of training of 60° at each port. The gun is transferred at pleasure from one port to the other by the movement of the turn-table, and commands an arc of 120°. The weight of iron is 150 tons per gun, the cost £7500 per gun; but in considering the cost of this arrangement it should be observed that by it one gun does the work of two.

Plate X.

In the turret one or two guns are placed in the interior of a cylindrical wall of iron armor closed overhead with ordinary bomb-proof covering. The turret with its contents is revolved by steam or other motive power, so that each gun commands a whole circle. Various arrangements have been designed for the service of the gun,—in one the loading is done inside the turret, in another under the glacis, in a third while the turret is being turned to the rear,—but whatever the arrangement, no time need be thereby lost, as the guns may be so placed that one revolves into action, while the other revolves out of action for loading. It would seem that a breech-loading arrangement for heavy guns would lend itself more readily to the turret form of construction. With an armament of breech-loaders, the turret might be reduced in internal diameter; the port opening need be no larger than the chace of the gun, which would not have to be withdrawn for loading, and which is laid by means of a small aperture contrived in the roof of the turret—the man who lays the gun having the machinery under his hand, and "training" the turret and gun himself in any direction. In turrets provision is made in the basement in the usual way for the accommodation of the garrison, and for the storage and service of the ammunition, as well as for the motive power and machinery. Special arrangements are made for ventilation and for the escape of smoke. The surface of the exterior to a certain distance in advance of the turret is plated with iron and sloped upwards "en glacis," so as to cover the base of the turret, and protect the turning gear from dislocation under the blows of heavy projectiles. See Plate X., fig. 1.

Before quitting this subject it may be well to offer a few remarks on the employment of cupolas or turrets on land defences. Either of these forms of iron construction may be advantageously employed in advanced positions where it is necessary to retain guns until the very last—such as the salients of ravelins, and in the angles of fronts of fortifications; also in points which are commanded from heights in their vicinity. As these constructions are indestructible by the direct fire of siege guns, and are absolutely safe from enfilade and reverse fire, they confer very great advantages upon the defence. They should mount heavier guns than can be brought against them; they cannot be silenced by the concentration of any number of light guns, and, judiciously used, they should place the artillery defence above the artillery attack. They render the construction of the first batteries of attack far more difficult, and force them to open at a greater distance from the place; and, at any period of the attack, they can meet its artillery with heavier metal. The guns of the attack are practically limited to about the calibre of the 64-pounders, and comparatively light armor will withstand these, and will preserve in security and render more easy the service of guns at least two calibres higher. Such constructions have been made by the Belgians in the detached forts round Antwerp and in Antwerp; by the Germans in the detached forts round Metz and in Metz, on the Rhine, and on the Weser; and by the Russians. In England there has as yet been no occasion to resort to them.

In some at least of the places mentioned above, a system of construction and a material advocated by Grusen have been employed; a type is shown in Plate X., fig. 2. The plates which are made of chilled cast iron manufactured by the Grusen process, are fitted together, without screws or bolts, in a simple manner. Each plate is a segment of the cupola, and is grooved at the edges; the segments are placed in position, and melted zinc is poured into the grooves, forming a close and solid joint. A glacis similarly constructed protects the base, which is set in motion by hand machinery. The interior arrangements do not differ in principle from those described above for turrets. It is said that such a turret weighing 133 tons can be made to revolve round the whole circle by four men in three and a half minutes. Its cost is about £16,000.

The Grusen metal is reported to have a very hard exterior surface, with great interior toughness and tenacity, and may probably be used with advantage in cupolas for land defence; but the experience in England does not lead to the conclusion that it is a suitable material for resisting the extremely heavy projectiles carried by the war ships of the present day. Particular attention has been directed to the nature and manufacture of armor plates in Britain, and, up to the present time, the results afforded have been most satisfactory. The iron employed is best described in the wording of the specification for manufacture, viz.:—"The plates must be soft, fibrous, thoroughly welded, and capable of offering good resistance to cannon shot, without indication of brittleness, and without the separation of the several moulds of which they may be composed." This specification was adopted after many experiments with hammered and rolled plates, in which the former, in consequence of the absence of fibre, conspicuously failed in comparison with the latter.

The best material for armor plates is, however, again prominently under consideration; so great an increase in penetration was obtained with chilled iron shot that the manufacture of steel projectiles was stopped as far back as 1866. Great advances have since taken place in the processes by which steel is made, and steel projectiles of great penetrating power have recently been under trial; by the use, too, of prismatic powder disposed in cartridges with a definite amount of air space, by which the combustion is rendered more gradual and more thorough, a far higher velocity is obtained with a materially diminished strain upon the chamber of the gun. This has rendered it possible to enlarge the chambers of the heavy guns and to increase their lengths by several calibres, with a resulting increase in energy of about one-third, so that a plate which would keep

out a projectile of 800 ℔ weight from a 38-ton gun will now barely keep out a projectile of 400 ℔ from an 18-ton gun. It is not impossible, however, that by a combination of iron and steel the resistance of armor may be again brought up to the penetrating power of projectiles. During this consideration many curious and unexpected results have been obtained, but they have not been reduced to such a form at present as to modify what is stated above. The whole question is, however, full of interest, and will, it may be anticipated, receive considerable development before long.

Armament of Fortresses.

The Systems of Fortification having been briefly described, it is right to say a few words here respecting the means of defending a place after it has been fortified. It is difficult to lay down exact rules as to the proportion of ordnance, ammunition, and stores of all kinds required for the defence of a fortified place, seeing they must necessarily vary according to the particular situation of each fortress, the system on which its works have been constructed, and the species of attack to which it may be exposed. If, for example, one of the sides be covered by a morass, swamp, or other obstruction which it is difficult or perhaps impossible to surmount, it must be obvious that a smaller proportion of artillery will be required than if the fortress were equally accessible on every side; and, on the other hand, a maritime fortress, accessible at all points, will necessarily require for its defence a larger proportion of ordnance than if it were only assailable on one or a few of these points. Where every front is equally exposed to attack, all must be equally prepared.

On this subject, however, certain maxims have been established, of which the following appear to be the most important. First, the proportion of ordnance, ammunition, and stores should never exceed the quantity necessary for a brave and resolute defence. Secondly, those fronts which are considered the most exposed to attack should be the most completely armed, whilst a partial armament of the remaining fronts may suffice. Thirdly, to the front to be attacked the following pieces of ordnance should be allotted, viz., to each Bastion, 1 for the salient, 5 for each face, 3 for each flank; to the Ravelin, 5 for each face; to the Lunette, 3 for each face, and a few pieces for the places of arms in the covered-way;—so that if one front be completely armed, the proportion of ordnance will be 17 for the Bastion, 10 for the Ravelin, 6 for the Lunette, and 6 for the places of arms,—in all a total of 39 pieces for the front. This proportion is less than has been fixed by many authorities, but the range and accuracy of guns have so increased since the introduction of rifled ordnance that it will be necessary to provide a traverse for every gun on the most exposed faces, and this, while it affords security to the artillery, materially diminishes the space available for mounting guns. It may be thought by some that this arrangement provides too much traverse shelter, but a few well-protected and well-served guns are better than double the number in exposed positions. Fourthly, when a place is exposed to attack on two contiguous fronts, the armament of each should be augmented one-half; when it is threatened with attack on detached fronts, the armament should be doubled. Fifthly, each of the other fronts should merely be provided with such a proportion as to secure it against insult. From this it may be assumed that a hexagon having only one front liable to attack should be completely armed on the two adjoining fronts, and that about seven guns per bastion and seven per outwork will be sufficient for the remaining fronts, and that a total of 178 pieces of ordnance will be sufficient for a hexagon.

The next consideration is the proportion which the several kinds of ordnance should bear to one another. Ordnance of the higher calibres is not the only ordnance which ought to be employed; in many cases medium and light guns are more efficacious; for when only troops or working parties are to be fired at, light guns will answer every purpose; their range is nearly equal to that of larger guns, and they are more manageable and may be worked with greater rapidity. Short guns of heavy calibre which throw heavy charges of case and shrapnel are best adapted for the flanks; and, generally, the largest or heaviest ordnance should only be employed to destroy the besiegers' batteries and dismount their guns. The light guns, as they can easily be withdrawn, should be placed in the covered-way, in the places of arms, and in the outworks of every description. The heavy guns and mortars, which are not so easily moved, should be within the body of the place, and as they require large charges of ammunition, they should be less frequently used, and only upon urgent occasions. A judicious economy of ammunition is a duty incumbent upon every commandant of a fortified place. The conduct of General Chassé in the defence of the citadel of Antwerp was a model in this respect. From the commencement till the close of the attack, scarcely a single shot was needlessly expended by the garrison.

Attack and Defence of Fortified Places.

Having brought the discussion of Permanent Fortifications to this point we may now consider the attack of fortified places, the general system of which was introduced and perfected by Vauban, so that it has ever since served as a model for the plans of his successors.

> "La résolution des siéges," says the Marshal, "est une affaire de cabinet. Elle est une suite naturelle de la supériorité que l'on croit avoir sur ses ennemis; mais leur exécution étant une des plus sérieuses, des plus importantes, et des plus difficiles parties, elle demande aussi le plus de mésure et de circonspection." He then goes on to state that the success of sieges depends on several circumstances, such as "1. Du secret, sans lequel il est difficile de réussir; 2. Des forces que l'on a sur pied pour attaquer les places des ennemis, et défendre les siennes; 3. De la disposition des ennemis; car s'ils sont réunis, et aussi forts que nous, ils peuvent nous empêcher d'en faire; 4. De l'état des magasins les plus à portée des lieux sur lesquels on peut entreprendre; 5. De la conjoncture des tems, parce que tous ne sont pas propres aux siéges, et rien n'étant plus ruineux que ceux d'hyver, on les doit éviter tant qu'on peut; 6. Des fonds nécessaires à leurs dépenses; car l'argent est le nerf de la guerre, sans lui on ne sçauroit réussir en rien. Ce sont là des mésures à prendre de longue main, qui doivent être dirigées à loisir; et aprés tout cela, quand on croit les avoir bien prises souvent tout échappe; car l'ennemi, qui n'est jamais d'accord avec vous, pourra vous interrompre. . . . Il faut bien peser toutes ces considérations, avant que de se déterminer; et prendre toujours si bien son tems, que l'ennemi ne puisse vous tomber sur les bras avant vos établissemens."[1]

A siege, therefore, being one of the most arduous undertakings in which an army can be employed,—one in which the greatest fatigue, hardships, and personal risk are encountered, and in which the prize can only be won by complete victory,—it is obvious that upon the success or failure of such an enterprise may depend the fate of a campaign or of an army, and perhaps the existence of a state. Of this the failures before Pavia in 1525, before Metz in 1552, before Prague in 1557, before St. Jean d'Acre in 1799, and before Burgos in 1812 present instructive examples. By the first France lost her monarch, the flower of her nobility, and all her Italian conquests; by the second, she was saved from destruction, whilst 30,000 of her enemies perished; by the third, the greatest warrior of his age, Frederick the Great, was brought to the very brink of destruction; by the fourth, the most successful general of France, and perhaps the greatest commander that any age or country has produced, was stopped short in his career of victory; and by the last, a beaten enemy gained time to recruit his forces, concentrate his scattered corps, and regain that ascendency of which the victory at Salamanca had for a time deprived him.

It is therefore of the greatest importance to a state that the sieges undertaken by its armies should be carried on in the best and most efficient manner possible, or, in other words, that by a due combination of science, labor, and force these operations should be short and certain, and without excessive expenditure of life. But the sieges undertaken by the British have seldom, if ever, united these three indispensable conditions; and with regard to those which took place during the contest in the Peninsula, it is well known that defects of organization, particularly the want of a body of men, such as sappers and miners, trained to the labor required at sieges, and an inadequate supply of material, necessitated a partial departure from established principles and rules of attack, which led to a waste of life unprecedented in modern sieges. Till late in 1813 the army had not a single sapper or miner; regular approaches were therefore difficult if not impracticable. It was necessary, in almost every case, to take the bull, as the saying is, by the horns; the last operation of a siege scientifically conducted, namely, battering in breach, was amongst the first undertaken; and the troops, marched to the assault whilst the defences remained nearly entire, were exposed to every species of destruction which the unreduced means of the besieged could bring to bear against them. The army of a country which has outstripped all others in the useful arts and in mechanical improvements was left wholly unprovided with those appliances which at once economize life and labor, and serve to render both most effectual for the purposes to which they are applied. Nevertheless, it may be observed that, in all periods and in all countries, the means employed for the reduction of fortresses have generally increased and become more overwhelming and irresistible in proportion to the advancement of knowledge and to the improvement of the useful arts; and that in Europe during the last two centuries, the extension of wealth and knowledge, accompanied by an unprecedented development of talent, directed towards military movements, has caused the results of sieges, and indeed of almost all the operations of war, to depend much less on individual exertion or casual displays of heroism, than on combination and expenditure. This may be made apparent by a slight retrospect of the sieges of the 16th century.

---

[1] *De l'Attaque et de la Défense des Places*, pp. 1 and 2. Hague, 1737, 4to.

At the period referred to, the art of disposing the several works of a fortress so as to cover each other, and to be covered by their glacis from the view of an enemy, was unknown; whilst the limited supply of artillery, its unwieldiness, and the great expense and difficulty in moving it rendered it so little available for sieges, that the chief object in fortifying towns was to render them secure against escalade and surprise, by means of lofty walls or altitude of situation. All places fortified prior to the 16th century are invariably of this construction. And as the simplicity of the fortresses to be attacked necessarily gave the same character to the operations directed against them, so, in those days, much was effected by daring courage, without the aid of science; and gallantry in individual combat, and fearlessness in confronting danger, were esteemed the highest qualities of a besieger. Thus contests dragged on for months, in petty but sanguinary affairs, and the most persevering or the most hardy troops, however ill organized or supplied, were the most dreaded, and not unfrequently the most successful. But when artillery became more movable, and large quantities were employed in sieges, lofty and exposed walls no longer opposed an adequate barrier; large breaches were speedily effected; places which had formerly resisted for months were carried in a few days; and so, in order to restore an equality to the defence, it became necessary to screen the ramparts from distant fire. The attempt to gain security by concealment rapidly advanced, whilst the means of the besiegers remained the same; and between the middle of the 16th and commencement of the 17th century works were so skilfully disposed and so well covered that the defence of towns obtained a temporary superiority over the attack. Of this the obstinate and successful defences made by the Dutch against the Spaniards during the reigns of Philip II. and Philip III. may be cited as remarkable examples.[1]

The pre-eminence of the defence over the attack was mainly due to the great difficulty of dragging up heavy ordnance with a besieging army, so that, the weight of metal being generally in favor of the besieged, the fire of the fortress was able to subdue that of the batteries of attack Vauban, however, in the reign of Louis XIV., restored the preponderance of power to the attack by the invention of ricochet fire, as the guns of the besieged were thereby dismounted or disabled at an early stage of the siege, and the besiegers being relieved in great measure from the effects of a direct and powerful fire of artillery, were enabled to push forward their approaches by the sap. Vauban also matured into a system the attack, by laying down rules for the establishment of parallels, for the position of enfilade and other batteries, and for the general conduct of the approaches. The real type of an attack is a *moving parapet*, the besieger carrying forward with him his cover, and thus depending for his success not so much on his offensive as on his defensive arrangements. It was by this combination of science and labor, aided by the steady advances of brave and well-trained sappers, that the reduction of fortresses which would have resisted for ever the rude assaults of the most determined enemy was rendered comparatively easy and certain.

These increased means of attack, to which it was found impossible to oppose a successful resistance, caused the art of concealment or covering to be further studied, till at length, in well-constructed fortresses, not a single wall remained exposed to view, and the sap and the mine became as necessary as the gun and the mortar to the success of a besieger. To render this intelligible to the general reader, a descriptive sketch of the progress of a modern attack, from the excellent work of Sir John Jones already referred to, is introduced here.

> "The first operation of a besieger," says that able and experienced engineer, "is to establish a force able to cope with the garrison of the town to be attacked, at the distance of some hundreds of yards from its ramparts. This is effected by approaching the place secretly in the night with a body of men, part carrying entrenching tools, and the remainder armed. The former dig a trench in the ground parallel to the front to be attacked, and with the earth that comes out of the trench raise a bank on the side next to the enemy, whilst the latter remain formed in a recumbent posture, in readiness to protect those at work, should the garrison sally out. During the night this trench and bank are made of sufficient depth and extent to cover from the missiles of the place the number of men requisite to cope with the garrison, and the besiegers remain in the trench during the following day, in despite of the fire or sorties of the besieged. This trench is afterwards widened and deepened, and the bank of earth raised, forming a covered road, called a parallel, which embraces all the fortifications to be attacked; and along this road, guns, wagons, and men securely and conveniently move, sheltered from the view and the missiles of the garrison. Batteries of guns and mortars are then constructed on the side of the road, to oppose the guns of the place, and in a short time, by superiority of fire, principally arising from situation, silence all those guns which bear on the works of the attack. After this ascendency is attained, the same species of covered road is, by certain rules of art, carried forward, till it passes over all the exterior defences of the place, and touches the main rampart wall at a spot where it has been previously beaten down by the fire of the batteries erected expressly for the purpose in the more advanced parts of the road.
>
> "The besiegers' troops, being thus enabled to march in perfect security to the opening in the walls of the place, assault it in strong columns, and, being much more numerous than the garrison defending the breach, soon overcome them, the more easily as they are assisted by a fire of artillery and musketry directed on the garrison from portions of the road only a few yards from the breach,—which fire can at that distance be maintained, without injury to the assailants, on the defenders of the breach until the very instant of personal contention. The first breach being carried, should the garrison have inner works, the covered road is by similar rules of art pushed forward through the opening, and advanced batteries are erected in it to overpower the remaining guns of the place; which effected, the road is again pushed forward, and the troops march in security to the assault of breaches made in a similar manner in those interior works, and invariably carry them with little loss. But as it is always an object to preserve the life of even a single soldier, so when time is abundant, the loss of men attendant on the assault of breaches under these favorable circumstances may be avoided, by pushing up the covered road through the breach, without giving the assault, and thus, by art and labor, the strongest defences frequently fall without any exertion of open force."

From this description it must be obvious that the most important object at a siege is to carry forward the covered road to the walls of the place, that all the other operations are secondary to and in furtherance of such an advance, and that hence the efficiency of armies at sieges depends upon their ability to complete the road at a small expense of life. But as this covered road advances, the difficulty increases. At its commencement, the work, being many hundred yards from the fortifications, can be performed by the common soldiers. But when the road or trench has arrived within a fair range of musketry from the place, then particular precautions are required; yet the work at this stage is not so difficult as to prevent its being executed by soldiers who have had a little previous training. At the last stage, when the approaches have been pushed close to the place, when to be seen is to be killed, when mine after mine blows up the head of the road, with the officers and men on the spot, when the space becomes so confined that little or no front of defence can be obtained, and when the enemy's grenadiers sally forth every moment to attack and deal out destruction to the workmen,—then the work becomes truly hazardous, and can only be performed by selected brave men, called sappers, who have acquired the difficult and dangerous art from which they derive their name. An indispensable auxiliary to the sapper is the miner, who in the exercise of his art requires even greater skill, conduct, and courage. The duty of a miner at a siege is to accompany the sapper, to listen for and discover the enemy's miner at work, and to prevent his blowing up the head of the road, either by sinking a shaft down to and meeting him, in which case a subterranean conflict ensues, or by running a gallery close to that of his opponent, and forcing him to desist from working by means of suffocating compositions, and by various arts the knowledge of which he has acquired from experience. Without the aid of skilful miners, sappers would be unable to execute that part of the covered road forming the descent into the ditch, not to mention other operations in the progress of which the assistance of the miner is equally indispensable; and without their joint labors and steady co-operation, no besiegers' approaches would ever reach the walls of a fortress. In the British service they are blended into one honorable body, the Royal Engineers.

---

[1] *Journals of Sieges in Spain*, by Colonel Sir John T. Jones; Preliminary Observations on the Attack of Fortresses.

But a siege, though it calls for personal bravery, unremitting exertion, and extraordinary labor in all employed, if scientifically prosecuted, is certain in its progress and its result. More or less skill and exertion in the contending parties may prolong or abridge its duration; but the sapper and the miner, when skilfully directed and adequately supported, will ultimately surmount every obstacle. On the other hand, sieges undertaken by armies imperfectly supplied with these auxiliaries are hazardous in the extreme. The only chance of success consists in scrutinizing the exterior of the fortress, in order to discover some spot whence, from the irregularity of the ground, or fault of construction, the main escarp wall may be seen at a distance sufficiently great to enable the ordinary working parties to approach with the covered road, and there to establish batteries for breaching or forming an opening through it into the place. When this is effected, the troops advance to the assault of the breach, as in the 16th century, thus passing from the shelter of the covered road into the fire of the place at the moment when it becomes most powerful and destructive; and as the fire of the besiegers' distant batteries is necessarily suspended during the assault, lest it should destroy the storming party, the garrison can with impunity mount the ramparts and employ every kind of weapon, missile, and instrument in their defence. All the chances are thus in favor of the besieged; for should the columns of attack, under these disadvantages, arrive in good order at the brink of the ditch, they must descend into it down a wall from 14 to 16 feet in depth, which cannot fail to break their order and throw them into confusion; and as no new formation can be attempted in a spot where death meets them in every shape, the assailants rush to the breach more like a rabble than a solid column. From this moment success hinges on the individual bravery of the officers and men, and the unshrinking firmness of the general commanding, in encouraging and supporting their efforts. But although these qualities, when united in a high degree, may, at a great sacrifice of life, enable the assailants to overcome all resistance, yet an assault of this nature, under ordinary circumstances, has almost always proved unsuccessful. Indeed, it may be laid down as the result of experience that, should an army unprovided with sappers and miners, and with the materials and means to render their services efficient, be opposed to a place fortified according to the modern system, with its walls completely covered, all the usual methods to reduce it would prove unavailing; no period of time nor sacrifice of men would be sufficient to purchase success, and the prudent course would be to decline an attempt pregnant with hazard, perhaps ruin.

> "These considerations," says Sir John Jones, to whom we are indebted for the above account of the various modes of attacking fortified places, "have for many years had their due weight with the great powers of Europe, and have induced them to form and keep up, as integral portions of their military strength, every necessary auxiliary for the reduction of fortresses; and sieges have in consequence become certain and comparatively bloodless. But England, constitutionally jealous of permanent military establishments, has always discountenanced military organization and military preparation till the hour of need, and with respect to sieges, which are rare, and exclusively offensive operations, has even carried her jealous feelings beyond the bounds of rational prudence; for, possessing a corps of officers professionally educated and well grounded in the science of attack and defence, she has denied them every requisite establishment to render their acquirements availing, and has most unreasonably expected her armies to reduce the skilfully fortified and well-governed places of the 19th century with means inferior to those used against the exposed and ill-constructed places of the 16th and 17th centuries."

And what was the immediate consequence of this irrational jealousy and niggardly parsimony? Contrary to all ordinary calculation, the fortresses garrisoned by the French in Spain were reduced; but at what a prodigious expenditure of life was this effected! In the several attacks upon Badajoz, two of which from extrinsic circumstances proved abortive, a little army was sacrificed; as many men, in short, as would have been sufficient for ten sieges undertaken with adequate means, and conducted according to the ordinary rules of science. But this is not to be understood as involving any reflection on the military talents of the general or the professional ability of the engineers. General Foy, in his work on the war in the Peninsula, has indeed made such a charge, condemning the mode of attacking fortresses adopted by the British in Spain as unskilful and inefficacious, and bringing it forward as indisputable proof of the low state of their military knowledge. But it should be recollected that the adoption of this mode was not a matter of choice, but of necessity, and that, if it was in its nature rash, hazardous, and inefficient, the fact of its having been directed against Ciudad Rodrigo and Badajoz with such rapidity of development and certainty of result as to outstrip the calculations of the French marshals, deceive the vigilance of French governors, paralyze the science of the French engineers, and baffle every defensive effort of the French garrisons, is surely no evidence of deficiency in military talent and professional skill. The objections to this mode of attack are insurmountable and decisive; that it succeeded in the instances referred to is merely a proof of what British soldiers, even when acting under the greatest disadvantages, are capable of accomplishing. These remarks are, however, no longer applicable. Since the Crimean war great attention has been bestowed upon the education and training of sappers and miners, and though England has neither the numbers of men nor the quantities of stores possessed by Continental nations, yet what she has of each is of the best. Every advance in science, if applicable, has been at once adopted into the military service; and as our civil engineers are as a body admittedly without superiors in the civil world, it may be confidently stated that in the military world our military engineers hold no inferior position.

Having thus given a general description of the methods of attack, we shall now subjoin, on high authority, a view of what is considered necessary for the proper defence of fortified places. An order issued by the French minister of war in 1813 contains directions on the subject which are almost universally applicable, and therefore deserve a place here. Every commander is directed to consider his garrison as liable to be unexpectedly attacked, and to pass at once from a state of peace into a state of war or siege, either by rebellion, by unlawful assemblies, by the presence of an enemy, by surprise, or by sudden assault,—in a word, by unforeseen causes, of which the history of war offers numerous examples. He is therefore ordered, even in time of peace, to fix his plan and arrangement for defence, according to such supposed attacks as may appear most probable, and to determine, for the principal cases which may be likely to occur, the necessary posts, reserves, and movements of the troops, and to take measures to ensure the due and active co-operation of every corps of the garrison. He ought, particularly, to make himself thoroughly acquainted with (1) the ground beyond the place which may be within the circle of action, of investment, and of attack; (2) the fortifications of the place, its interior, its buildings, its military edifices or establishments; (3) the garrison, the means of the place in artillery, in ammunition, and in other stores of every kind; (4) the population to be maintained in time of siege, the men capable of bearing arms, the master and journeyman artificers fit to be employed either on the works or in case of fire; and (5) the provisions, materials, tools, and other resources which the town itself and surrounding country can furnish, and which it might be necessary to secure in case of siege. In order to enable governors and commanders to comply with these instructions, which are clear and precise, the minister proceeds to detail their principal duties, according to the circumstances in which they may find themselves placed; but for these we must refer to the general order itself, which is a masterpiece of its kind, and in all probability emanated directly from Napoleon himself. Its object appears to have been to inspire a governor with hopes that, by taking proper precautions, and making a full use of means previously provided, the defence might be rendered equal, if not superior to the attack; and whether this be so or not, the importance of the directions embodied in the order is not diminished, and where they are duly observed the nature and extent of the resistance must be materially increased.

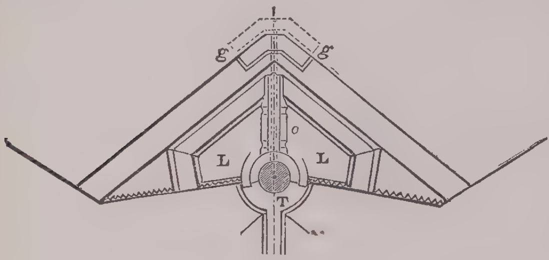

Fig. 67.—Lunette of Darçon.

The protracted and ablé defence of Sebastopol led many to imagine that the Russians by new defensive arrangements had solved the problem so long under discussion, and had again restored to the defence much of its former superiority over the attack. But the real merits of the Russian engineers consisted not in the discovery of new principles, but in the skilful application of those principles which, recognized at an early period, have been by degrees matured and enlarged. In estimating the comparative results of the attack and defence of Sebastopol, it must be remembered that neither can be judged by strict rules, as neither conformed to such rules. The north side being left open by the impossibility of investing both sides, the south became a detached line of powerful intrenchments, to the defence of which the whole force of an army, not a garrison, could be directed at will. The strength of the garrison, continually renewed from without, permitted the fullest use of detached works, which, when backed by a line in rear sufficiently strong to resist a *coup-de-main*, constitute one of the most powerful modes of defence. Such a fort or work was the celebrated Malakoff Tower, and the redoubt enveloping it, the type of which may be found in the lunette of Darçon, of which fig. 67 is a plan. In this lunette, intended to be prepared beforehand, T is a powerful tower, LL a lunette, which in this case is revetted, but might have been made, as at the Malakoff, a simple earth-work—*c* an underground communication to *g*, *g*, loopholed galleries for flanking the ditches. This sketch will show the general principle of defence involved in such works, but of course the form must vary in the hands of an able engineer, to suit the peculiarities of the ground. At the Malakoff the redoubt was made circular, but in principle it was strictly analogous to the lunette.

Siege of the Citadel of Antwerp.

Plate XI. We shall now, as an example give a sketch (abridged from the *United Service Journal*) of the attack on the citadel of Antwerp in 1832—first, because this was the most regular and scientific siege which had taken place for many years; and secondly, because as a practical operation an account of it must be more interesting and more instructive than any description of the formal theoretical plans which are usually drawn in the military schools. See Plate XI.

Without entering into any detail of the complicated circumstances out of which the siege arose, in a time of general peace, it may be stated here that Great Britain and France, as joint guarantors of the integrity and independence of Belgium, having failed to procure the evacuation of Antwerp by means of negotiation, were obliged to have recourse to force. Hence the siege is to be viewed as an ejectment executed against the king of Holland, who had refused to renounce possession, unless compelled to do so.

The French army employed to cover and conduct the attack of the citadel of Antwerp in November and December, 1832, was placed under the command of Marshal Gerard, and amounted to 66,450 men, viz.:—54,000 infantry, 6000 cavalry, and 6450 engineers, artillery, and pontonniers, with 14,300 horses, and 144 pieces of siege and 78 of field artillery. On the 24th of November Marshal Gerard established his headquarters at the village of Berchem, about 2500 yards from the citadel, and issued orders to commence operations in the evening as soon as it became dark. The garrison of the citadel, under General Baron Chassé, amounted to 4470 men, with 144 pieces of ordnance of all calibres, and abundance of ammunition and stores. It will be observed that a garrison of about 5000 men was opposed to the attack of a besieging army thirteen times its strength.

At eight o'clock p. m. on the 29th November, the French troops destined for this service, consisting of 18 battalions, 900 artillery, and 400 sappers, in all about 17,140 men, assembled at the dépôts of intrenching tools. The flank companies of these brigades, supported by twelve eight-pounders and a strong piquet of cavalry, formed the covering party under the direction of General Haxo, by whom and the officers of his department (the engineers) the first parallel and approaches were traced out, whilst General Nïègre and the officers of artillery marked the sites of the projected batteries. The first parallel leaned on the covered-way of the right face of Montebello, and extended towards Kiel, its nearest point being about 325, and its farthest 435 yards from the advanced front of the citadel. The extent of the first parallel was 1870 yards, and that of the approaches 3750 yards. The communications from the right and centre debouched from the Malines Chaussée, in the village of Berchem, parallel to the road leading from that village to the Harmony and St. Laurent; the communication from the left commenced near the garden called Heinrich's; whilst a fourth, on the extreme right, sprung from the covered-way of the left flank of Montebello, opposite to the first traverse.

On the second night, from 30th November to 1st December, five approaches were pushed on in front of the first parallel,—two in the direction of the capital of the Toledo bastion, two upon that of the Lunette St. Laurent, and one, being the fifth, terminating in a place of arms on the extreme left. From the 1st to the 2d December two zig-zags were added to the approaches,—one from the centre, in the direction of the gorge of St. Laurent, and the other on the right, diverging towards the curtain, between the Toledo and Fernando bastions. The badness of the weather sadly incommoded the workmen, and prevented the artillery getting the guns into battery. Between the 2d and 3d December four zig-zags were made in front of the approaches on the right and centre, and half a parallel was formed to complete the place of arms constructed on the left during the night of the 30th November. The heads of the zig-zags were advanced to within 135 yards of the glacis. The batteries Nos. 1, 2, 3, 4, 5, 6, and 9 (see Plate XI.), with two for mortars in the rear, were armed, and ready to be unmasked at a moment's notice. The arming of Nos. 7, 8, and 10, on the extreme left, was impeded by the difficulties of the ground. From the 3d to the 4th December, the second parallel was traced and commenced, its right leaning on the foot of the glacis of the counterguard, its centre and right 130 yards distant from the place of arms in the covered-way of the Toledo bastion, and its left towards the right of the covered-way of the St. Laurent, at 90 yards from the crest, and 15 from the foot of its glacis. The length of the second parallel was 1250 yards, and with its approaches from the first parallel it occupied 3025 yards of ground. By the greatest exertions batteries Nos. 7, 8, and 10 were armed during the night. This completed the armament, and, at 11 a. m. on the 4th, the embrasures were unmasked, and the batteries opened their fire from centre to flanks, and maintained it steadily during the day.

From the 4th to the 5th of December an approach was pushed on from the second parallel, directly upon the salient angle of St. Laurent, and an entry was made into the covered-way by a return to the left. The garrison discovered this, and opened a sharp fire from the lunette; a lodgment was, however, effected near the spot usually occupied by the first traverse. At this time the garrison suffered much from the fire of the besiegers. From the 5th to the 6th the lodgment made the previous night in the covered-way of the salient place of arms of St. Laurent was prolonged as far as the first traverse. But the besieged kept up so vigorous a fire that the French engineers were obliged to renounce the flying and adopt the full sap. The zig-zag in the counterguard, being about three feet in width and four in depth, was conducted along the parapet, nearly to the extremity of the right flank, and within 180 yards of the counterscarp of bastions Toledo and Fernando; and two lodgments, blinded with fascines, were made in the parapet for six guns to enfilade the covered-way of the Toledo bastion. In the mean time a steady fire was kept against Kiel, the ravelin in its rear, and the Paciotto bastion. From the 6th to the 7th a battery of 24-pounders near the village of Burcht on the left and Hoboken on the right opened on the gun-boats which flanked the French post at the Melk Huys. It was intended to assault St. Laurent this evening; but as the lunette was found to be

well protected by *trous-de-loup*, the project was abandoned, and the regular method of descent, passage, and mine determined on.

Between the 7th and 8th of December a shell penetrated the blindage of the laboratory, and, setting fire to the combustibles in it, caused considerable havoc. A battery for six mortars, E, on the right, now opened its fire; another, F, also for six mortars, was traced behind the centre of the parallel; and platforms for four mortars were laid near Montebello. The fire of these batteries was directed on the Toledo bastion and the buildings within it. On the previous day jets of flame had been seen to issue from the Great Barracks, and, in spite of every exertion, the building was entirely consumed by the evening of the 8th.

From the 9th to the 10th of December the operations against St. Laurent were renewed with great activity, and the sap advanced to the crotchet of the second traverse, whilst that intended to debouch upon it from its right was likewise pushed on. The third parallel was opened 130 yards in advance of the second, its right debouching beyond the Boom Chaussée, from the branch running into the covered-way of the counterguard, and its left uniting with the boyau parallel to the foot of the glacis of St. Laurent. The garrison suffered much from the vertical fire of the mortars and howitzers, especially the great mortar and the new-model eight-inch howitzers. Until the year 1822 the eight-inch howitzer in common use in France measured 3 feet 6 inches French, and weighed 1096 ℔, or twenty-three times the weight of the loaded projectile, whilst its calibre was equal to a solid shot of 80 ℔, and contained 65 ounces of powder. The new-model howitzer was an improvement on the Russian licorne and the Spanish heavy howitzer, perfected by Colonel Paixhans. The raft for the blinded descent into the ditch was brought up to the lodgment, and a second descent *à ciel couvert* was commenced to the left of the first. The third parallel was improved and widened. A little after dusk on the 10th the besieged made a sortie, which was driven in, but not until damage enough had been done to occupy the French all the night of the 10th and the morning of the 11th in repairing it. From the 11th to the 12th three rafts were got ready, and placed in the descents to the ditch; they were about 12 feet by 8. At dusk the miners returned to the escarp, and, in an excavation made the previous night, fixed two petards, which, by their explosion, produced a fissure in the wall, and a sergeant having immediately entered the hole, commenced a gallery under the centre of one of the arches. At 11 A.M. on the 12th the battery H, on the extreme right of the second parallel, opened fire, which, combined with that from the others, told severely on the Toledo bastion. The miners still continued their work under the lunette St. Laurent, and commenced chambers for three mines. The fourth parallel was widened during the day.

Between the 12th and 13th of December the miners were at work in the chambers under St. Laurent, which were not yet completed. On the right the covered-way of the left face of the Toledo bastion was crowned to within 65 yards. From the 13th to the 14th, after nearly sixteen nights of open trenches, the arrangements for the assault of St. Laurent were completed, and orders were issued to prepare for the storm. Too much value was set on this outwork, defended by little more than a hundred men, one five-and-a-half-inch howitzer, two Coehorn mortars, and a six-pounder. The mines being charged, the blinded descent into the ditch was pierced as soon as it became dark, and everything prepared for the assault. Three storming parties of the flank companies of the 65th regiment of the line were posted in readiness, with a column of reserve; and at 5 A.M. on the 14th the match was applied to the saucissons of the mines. Three successive explosions took place, and the escarp immediately presented a wide and practicable breach. The fascines for crossing the ditch had been injured by the explosions, but after a little delay the storming party entered almost without opposition, and made prisoners one lieutenant and forty-eight rank and file, the others having escaped into the citadel. Thus fell the lunette St. Laurent.

After this operations were carried on against the citadel, and at 11 A.M. of the 21st December the battering in breach commenced, and continued until the 23d. When a practicable breach had been formed, and Marshal Gerard was about to deliver the assault, the garrison surrendered, after a gallant defence, remarkable, however, for its passive rather than for its active character. When Marshal Gerard entered the fortress, General Chassé was found in a casemate in the Alba bastion, which he had occupied during the siege. On their progress from the gate to the governor's quarters, they passed through a scene of desolation and ruin which baffles description; with the exception of the principal powder magazine, two or three service magazines, and the hospital, not a building remained standing. The terrepleins of the bastions were ploughed into deep ruts by the shells; the gorges were encumbered with heaps of fallen rubbish; and though the casemates and subterranean communications were not perforated, all of them had sustained damage from the incessant explosion of shells, and they emitted an almost insupportable odor, caused by the number of men who had been crowded into them. When Count Gerard took his leave of General Chassé, he observed "that it was high time to surrender, that he had gallantly and honorably done his duty, and that he ought not to have held out a day longer." With a fortress reduced to a heap of ruins, a garrison exhausted and attenuated, and a breach sufficiently wide to admit a column formed upon a front of a hundred, it would indeed have been madness to attempt to stand an assault.

The following is a list of the different batteries, with the direction of their fire respectively:—

	No. of Batteries.	24 Pounders.	16 Pounders.	8-inch. Howitzers.	10-inch Mortars.	Distance in Yards.	Direction of Fire.
Opened on the 4th and 5th December.	1	6	..	2	..	535 & 550	Battering the left face of Toledo, and gorge of St. Laurent.
	2	..	2	2	..	500	Ricochetting the left face of Toledo.
	3	4	..	2	..	640	Battering the left face of the Ravelin.
	4	..	3	2	..	650	Ricochetting left face of the Ravelin.
	5	6	2	1	..	680 & 430	Battering right face of Toledo, and ricochetting left of Toledo.
	6	..	2	2	..	700	Ricochetting left face of Toledo.
	7	6	2	1	..	380 & 700	Ricochetting left face of St. Laurent, and battering right face of Paciotto.
	8	..	3	2	..	465	Ricochetting left face of Ravelin
	9	..	..	6	..	820	Battering salient angle of Paciotto.
	10	8	..	..	..	650 & 520	Battering left face of Ravelin, and Lunette of Kiel.

	K	..	..	..	8	600	Do.
	14	6	..	..	..	50	Breaching battery.
	15	6	..	..	..	350	Counter-battery against the left flank of Fernando.
	16	..	..	..	..	125	Six pierriers on the Ravelin and Toledo.
	I	..	..	..	10	250	Terreplein and rampart of Toledo.

Out of their force of 66,450 men, the French lost during the siege 108 killed and 695 wounded—total, 803. The Dutch had 4937 men in the garrison, of whom they lost 122 killed, 369 wounded, and 70 missing—total, 561.

A careful comparison of the details of this siege with the general principles which have been enunciated will enable the reader to recognize the importance of the following maxims:—

1. Independently of the great amount of labor to be provided for in the construction of parallels, approaches, and batteries, there will be a daily drain upon the besieger's forces by casualties, so that he can scarcely expect success unless his original preponderance in numbers has been such as to leave him at the final moment of assault in a condition to attack the diminished garrison with an overwhelming force. In addition, therefore, to a covering army when external relief is threatened or anticipated, the besieging army should be from four to five times the strength of the garrison, or even more, should the nature of the ground add to the ordinary difficulties of approach. This superiority of force is necessary to give celerity and steadiness to the operations, which would otherwise be tedious and interrupted.

2. A perfect investment is not merely expedient but indispensable. So long as any portion of the enceinte of a fortress is left open the garrison is able to recruit its strength from without, and it is relieved from that moral depression which must oppress men when closed up within a narrow space, and exposed, day after day, to fatigue and danger. Under such circumstances there seems to be no limit to the power of defence, as fresh supplies of men enable the besieged to add intrenchment to intrenchment, and it is only possible to overcome him by determined, reiterated, and overwhelming assaults. Such were the circumstances of Sebastopol; the system of attack forced upon the allies never enabled them to isolate even the southern section of the fortress, and the means of communication between the south and north remaining available fresh troops were continually brought to the south side, and a superiority in numbers given to the defenders over the attacking force. It ought not therefore to be a matter of surprise that the progress of the siege was slow.

3. Good and secure lines of communication are most essential, as there ought to be no interruption after the ground is broken and the siege has commenced. Neither in the attack nor in the defence should guns be fired idly, or from distances and positions from which their fire would be useless or even uncertain; but when the proper distance has been ascertained, battery should succeed battery as the works of approach advance, and no interval for rest or for the repair of injuries should be allowed to the besiegers.

4. The importance of advanced works was well exemplified at the siege of Antwerp, where the whole force of the attack was directed against the advanced lunette St. Laurent, whilst the

defence, though good, had not the advantage of the collateral defence of the lunette Montebello (see Plate XI.). Where the garrison is an army, such works afford the best means for an obstinate defence, and, by forcing the besieger to act on the circumference of a larger circle, diminish very much his ordinary advantage of concentration.

Siege of Dantzic.

Having thus given an example of an interior and passive defence, we shall now, in further illustration of the principles already laid down, advert to an example of a different kind. The siege of Dantzic, whether considered with reference to the magnitude of the operation, the difficulties to be surmounted by the besiegers, or the active and varied character of the defence, was certainly one of the most memorable events in the campaign of 1807. Before the war of 1806 and 1807 the fortifications had been much neglected, because from the position of the place it was not anticipated that it would have to sustain a siege. But when the battles of Jena and Auerstadt had entailed destruction on the Prussian army, and had laid open the kingdom, General Manstein, who commanded at Dantzic in the absence of Field-marshal Kalkreuth, the titular governor, labored with much activity in repairing the walls and the palisades, and in completing the enceinte. It is necessary, therefore, to describe the principal defences at the time the place was invested by Marshal Lefebvre, at the head of the tenth corps of the grand army, and before the commencement of the trenches on the 1st of April.

The city of Dantzic, traversed by the Mottlau, was surrounded with large ditches filled from that river, the waters of which, retained by several sluices, formed, to the eastward, a vast inundation, which, reaching on one side to the suburbs of Oliva and St. Halbrecht, and on the other to the dykes of the Vistula, extended about four leagues, and covered two thirds of the eastern fronts. On the north the Vistula runs about 260 yards from the covered-way, leaving between the left bank and the glacis of the place an impracticable marsh intersected by canals; at its embouchure, distant nearly three miles, the banks were defended on the right by the fort of Weichselmunde, and on the left by an intrenched camp in the small island of Neufahrwasser, intended to cover and protect the arrival of such succors as might come from the seaward. The ground adjoining the banks of the Vistula being intersected by canals and covered with marshes, was extremely unfavorable to a besieger, as it rendered it difficult for him to form establishments or raise works of proper solidity, and forced him to extend his quarters, disseminate his troops, and multiply his posts. At the period in question this inconvenience was the more severely felt, because the besieging force, though nominally 18,000 strong, was inferior in numbers to that of the garrison, which consisted of 12,000 Prussians and 3 Russian battalions, and it required the most vigilant caution to occupy numerous posts without unduly weakening it. The communication between the place and the fort of Weichselmunde was maintained by a series of redoubts constructed on the borders of the Vistula, and particularly by the advantageous position of the isle of Holm, which continued the defence of the place to the fort with the exception of an interval of about 1400 yards, and renddered the communication with Weichselmunde by the canal of Laack secure in spite of any batteries which the besiegers could establish at Schellmühl. The French, therefore, could not attempt to throw a bridge over this part of the Vistula until they had made themselves masters of the isle of Holm. On the west two chains of hills, separated by the valley of Schidlitz, covered the enceinte; and the prolongations of these hills were crowned by the two forts of Bischopsberg and Hagelsberg, which, being connected by intrenchments, formed a second enceinte, leaning upon one side on the inundation of the Mottlau, and upon the other on the left bank of the Vistula. This new enceinte, though constructed of earth and without revetment, was secure against assault, and as the covered-way as well as the foot of the scarps bristled with strong fraises which served instead of revetments, the besiegers had no hope of succeeding by a *coup-de-main*, and were therefore obliged to proceed by regular attack.

From this description of the defences of Dantzic, it is easy to perceive that the difficulties attending the operation must have been very great. The principal of these, as stated by General Kirgener, who until the arrival of General Chasseloup directed the attack, were, first, that Marshal Lefebvre had at first an army inferior to that of Marshal Kalkreuth, all of those destined for the siege not having then arrived, and that this army was in a great measure composed of new troops; secondly that, owing to the badness of the roads and the inclemency of the season, the artillery experienced the greatest difficulty in bringing up its convoys, the establishment of the batteries was retarded, and a scarcity of ammunition sometimes prevailed; thirdly, that the place, which could not be completely invested because the approach from seaward was in the hands of the British, required an immense circumvallation, which, in fact, could not be completed until after the arrival of reinforcements; the corps of troops which occupied the quarters were extremely weak, and could neither furnish a sufficient number of workmen, nor even the number of men necessary for guarding the trenches; and fourthly, that the besiegers had no good plan of the place, and did not know the depth of the ditches, and as the accidents of ground in front of the fortifications were extremely diversified, they could only be reconnoitred in proportion as the works advanced. These circumstances, joined to the necessity of concentrating the greater part of the troops close to the camp of Neufahrwasser, by which succors arriving by sea might debouch, and the advantage which the besieged had in retaining the mastery of part of the suburbs, determined the chief engineer, after the investment had been effected, to direct the principal attack against the Hagelsberg, and a false one against the Bischopsberg fort. The true point of attack was the long branch of lines in the plain connected with the bastion on the right of the Hagelsberg: "c'était là le défaut de la cuirasse;" but, for the reasons above stated, approaches were directed against the fort itself.

As the details of this great siege would fill a considerable volume, all that our limits permit is merely to indicate the principal occurrences. On the 1st of February, 1807, the troops of General Dombrowski began to approach Dantzic, and took up a position at Mewe, upon the left bank of the Vistula. On the 15th General Menard, commanding the Baden contingent, arrived at the same point, and repulsed a detachment of the garrison of Dantzic, which had advanced from Dirschau to attack him. On the 23d General Dombrowski, having been reinforced, received orders to attack a large detachment of the enemy which occupied an advantageous position at Dirschau and its environs. The combat here was obstinate and sanguinary; but the Prussians, though intrenched in a church and a churchyard, were dislodged and driven back chiefly by the Poles, who, exasperated by their long resistance, put to death without mercy all who fell into their hands. After the combat of Dirschau, General Manstein no longer sought to obstruct the distant approaches. The troops destined to form the besieging army now arrived in succession, and the formation of the park of artillery was commenced. On the 12th of March Marshal Lefebvre found himself in a condition to close in on the place: and the troops of the garrison having withdrawn, he distributed his own in the following positions:—a battalion of French light infantry at Oliva, a Saxon battalion at St. Halbrecht in the Burgerfeld, and two at Tiefensee and Kemlade; the Poles occupied Schonfeld, Kowald, and Zunkendin; some battalions took post at Wonnenberg, Neukau, Schudelkau, and Sniekau; the Saxon cuirassiers and light horse were stationed at St. Halbrecht and Guirsehkens; the 19th regiment of French chasseurs at Burgfeld, and the 23d at Schudelkau; the Baden dragoons and hussars at Wonnenberg, and the Polish lancers at Langenfurt. On the 16th the marshal attacked the village of Stolzenberg, which he carried after a warm resistance, as he did also the suburb of Schidlitz, to which the Prussians had retired; and on the 18th the place was invested, with the exception of the eastern part, which, by the isle of Nehrung, communicated with Königsberg. Field-marshal Kalkreuth now arrived in Dantzic, and assumed the command of the place. The next operation of the besiegers was the attack of the isle of Nehrung, which, after a severe and protracted struggle, was carried in the most gallant manner, and measures were immediately taken to secure the possession of this important conquest. A bridge was also established on the Vistula, and various works constructed to check the attempts of the enemy either on the side of Dantzic or on that of Pillau. At this time the governor, who had under his command a garrison of 18,000 men, besides the burgher militia, made a sortie for the purpose of destroying the works of the besiegers; but the attempt failed, and the Prussian columns were compelled to retreat into the place without having obtained the smallest success upon any point.

It had been decided that the principal attack should be directed against the fort of Hagelsberg (because the redoubt of Bischopsberg was more complete and better flanked by the fire of the place), favored by two false attacks, the one directed against the intrenched camp at Neufahrwasser, and the other against Bischopsberg, and by two secondary attacks on the left bank of the river; and ground was broken on the night of the 1st and 2d April, at the distance of 1600 yards from the palisades. The approaches were pushed forward with the greatest vigor, and on the night of the 11th the second parallel was commenced by flying sap. On the morning of the 12th the batteries were armed. On the 13th the enemy made a sortie in force, attacked the Saxons with great impetuosity, carried a redoubt constructed upon the mamelon of Hagelsberg, and penetrated even to the head of the trenches; but they were ultimately repulsed, though not without difficulty and loss. By the 23d all the batteries of the first and second parallels, and those of Stolzenberg, were armed, and emplacements were provided for field howitzers, from which to throw shells into all quarters of the city. At daybreak on the 23d the batteries were unmasked, and, though the garrison returned the fire with the greatest vivacity, by the 24th the besiegers, firing with 56 heavy guns, had obtained the ascendency, committing great ravages in the place. Being apprised of this circumstance, Marshal Lefebvre summoned the governor, who replied in a manner worthy of himself. The fire of the mortar and reverse batteries continued during the 25th, in the course of which a new battery was constructed between the low flanks of the Stolzenberg, and the direction of some others changed, in order to batter the right bastion of Bischopsberg, the fire of which had greatly incommoded the French batteries. During the day of the 26th the fire on both sides was exceedingly animated; but at seven in the evening, that of the garrison suddenly ceased, and a column of 600 Prussian grenadiers, followed by 200 workmen, sallied out of the place. As the sortie had been foreseen, preparations had been made to repulse it. It was attacked in front and on both flanks; the whole column was either killed or taken prisoners. Meanwhile the works were vigorously pushed forward at all points. The batteries of Stolzenberg were united with the attack on the Bischopsberg; emplacements were prepared for batteries *à ricochet;* at the attack of the lower Vistula the works were continued, and a tongue of land situated at the extremity of the isle of Holm taken possession of and isolated by means of a cut, whilst at the principal attack the greatest exertions were made to prolong the right of the third parallel, and enlarge the communications. On the 30th April the batteries of the besiegers, augmented by several pieces which had arrived from Warsaw, thundered on the place, in different quarters of which conflagrations appeared; and the besieged replied by the fire of all the batteries of the front attacked, directing more than thirty pieces on a redoubt which fired with the greatest effect. But as the fire of the besiegers had made little impression on the exterior fortifications, which were of earth, it was during the first days of May directed chiefly against the palisades, and the utmost activity was at the same time evinced in extending, improving, and urging forward the attack; whilst, on the other hand, the garrison showed equal vigor in obstructing the approaches and destroying the works of the besiegers. In fact, notwithstanding the address of the French artillery, that of the garrison still remained effective, because it had not been possible to ricochet the lines of the fortifications, and the resources of the besieged in munitions of all kinds were more considerable than those of the besiegers.

On the urgent recommendation of General Chasseloup, who had by this time assumed the direction of the attack, it was decided that the isle of Holm should be assaulted, as the possession of it would enable the besiegers to take in reverse the front attacked. The besieged had spared no pains for the preservation of this important post, from a redoubt on which, called Kalke Schauze, they had continually annoyed the left flank of the trenches. In the night of the 6th and 7th of May, however, it was attacked, and carried after a desperate resistance, whilst the possession of it was secured by works added to the intrenchments which had just been stormed, and its batteries were turned against the place. At the principal attack the fire of the besiegers had also mastered that of the besieged; and Marshal Lefebvre was preparing to assault the fort of Hagelsberg, when on the 12th a Russian corps d'armee of 18,000 men, under the command of General Kamenskoi arrived by sea, and disembarked at the intrenched camp of Neufahrwasser.

At the moment of landing his troops, General Kamenskoi was ignorant of the capture of the isle of Holm, and he was disconcerted to find such an obstacle to his communications with the place. This occasioned delay which proved fatal to his enterprise; for had he attacked immediately on landing, it is not improbable that he would have succeeded. It was only on the 15th of May, however, the third day after the disembarkation, that he made an attempt to succor the besieged city. He began to debouch at four in the morning, and, under cover of a brisk cannonade, formed his force, consisting of 12,000 men, in four columns of attack. The onset was impetuous, and at first the Russians gained ground; but they were ultimately repulsed at all points, and forced to retreat with great loss to the intrenched camp. Field-Marshal Kalkreuth made no attempt to second this attack by a general sortie, which would have placed the French between two fires; and by its failure the fate of Dantzic was decided.

The works of the besiegers were now pushed forward with redoubled vigor; and the following day preparations were made for the assault of Hagelsberg. Foreseeing this, Marshal Kalkreuth resolved to make a last effort to destroy the nearest works of the besiegers, and for this purpose ordered a grand sortie, which took place on the evening of the 20th May; but although the Prussians fought with all the fury of despair, they were driven back, and pursued into the ditch of the place. On the 21st the besieging army was reinforced by the arrival of the troops of Marshal Mortier, part of which had remained before Colberg; the marshal himself quickly followed; and orders were immediately issued for the assault of Hagelsberg. Before giving the signal, however, Marshal Lefebvre again summoned the governor of Dantzic, who, having no longer hope of succor, and being convinced that the besiegers were in a condition to make themselves masters of the fort of Hagelsberg, showed a disposition to capitulate. A suspension of arms was accordingly agreed to, and this was followed, on the 24th of May, by a capitulation, the principal conditions of which were similar to those which the field-marshal himself had granted to the garrison of Mayence in 1793.[1]

These two sieges illustrate so well the principles of attack and defence, and are so perfect of their kind, that it has not been thought worth while to add an example of a more recent siege; but it should be observed that in future the preliminary operations of the besieger must take place at far greater distances; he will break ground for his first parallel at not less than twice the distance hitherto laid down, and will place his first batteries in rear of the parallel. This, while entailing on him much greater labor in parallels, trenches, and approaches, offers counterbalancing advantages, as it allows him to disperse his batteries in small units without the sacrifice of any of their power of simultaneous concentration on the point of attack, and with diminished exposure to the counterblows of the enemy's artillery.

BASTIONED SYSTEMS OF THE NETHERLANDS.

The Bastioned System of the Italians was carried into other countries by their engineers, who were extensively engaged in the service of foreign princes, and the celebrated Italian engineer Marchi, coming to Brussels with Margaret of Austria in 1559, appears to have introduced the Bastioned System into the Netherlands. It has been shown that in permanent defences, the ordinary earthen scarp adopted in ditches of field works had been replaced by a masonry revetment as a security against surprise, in consequence of which, in old Italian fortresses, lofty revetments were almost universal; but in a country the soil of which is permeated by water within a few feet of the surface, such a mode of guarding against escalade would have been enormously expensive, and the alternative was adopted of forming broad wet ditches round the ramparts, and by thus securing them from sudden attack, revetment became unnecessary. The first example of a fortress surrounded by simple earthen ramparts without revetments is said to be that of Breda, fortified in 1553 by Count Henry of Nassau, and this arrangement required only to be moulded into the bastioned trace to constitute the ancient system of the Netherlands, as described by Freitag in 1630. Freitag made the flanks of his bastions perpendicular to the curtain, the faces 98 yards long, with a flanked angle not exceeding 90°, and the length of the curtain 149 yards.

Freitag had strange notions respecting his profiles, regulating the height and thickness of his ramparts not so much by the resistance they were required to offer to artillery as by the *number of sides* of his polygon; but disregarding these vagaries of the systematist, the annexed cut (fig. 68) may be assumed to represent the profile usually adopted by the Dutch engineers, R being the body of the place, F the fausse-braye, D the ditch.

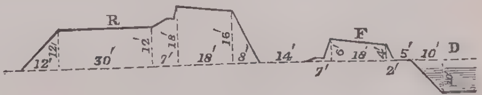

FIG. 68.

It will be observed that the main rampart is surrounded by an advanced parapet called a fausse-braye. This advanced parapet was intended to deliver a grazing fire on the ditch, whilst the space between it and the rampart formed a spacious *chemin des rondes* for the assemblage and movement of troops; but great as these advantages are, the fausse-braye has dropped into disuse. It is not possible to remain in it under a heavy vertical fire, the shells either dropping directly, or rolling down into it from the slope of the rampart above. Such *shell traps*, as they are called, are scrupulously avoided by modern engineers, who know that the improvement of vertical fire will ere long add materially to the difficulties of defence. In the bombardment of Sweaborg, an illustration was afforded of what may be expected of heavy mortars, when the shell becomes a better representative of a mine than it now is. At present a 13-inch shell weighs, when loaded, 200 pounds, and can carry a charge of 11 ℔ of powder, which is ample for breaking the shell and scattering its fragments, but is insufficient for producing the effects of a mine.

---

[1] See Dumas, *Précis des Événemens Militaires*, tom. xviii. p. 123.

The Dutch System of Coehorn deserves especial attention, and is represented in Plate IV., fig. 1, which exhibits his first system. The great characteristic in this system is the combination of wet and dry ditches, and the use of covering works, or couvre-faces, intended to preserve the body of the place from injury till an advanced period of the siege. These envelopes were first proposed by Dürer, and it is worthy of note that the remarkable orillon of Coehorn is a reproduction on a modern scale of the complicated casemated structure of one of Dürer's basteien. Coehorn was well acquainted with the principles and the systems of the eminent German engineer Speckle, and adopted them when applicable to his purpose. The profile (fig. 69) may enable the student to appreciate the difference between the dry ditches of Coehorn and the narrow passage afforded by the fausse-braye of the older engineers.

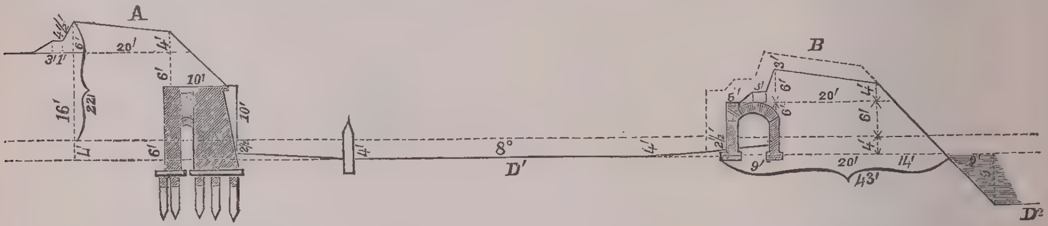

Fig. 69.—Profile of Coehorn's Bastion—A, inner or upper bastion; B, outer or lower bastion; D^1, dry ditch between the two; D^2, wet ditch.

The profile exhibits also the loopholed galleries of the counterscarp, by which a reverse musketry fire is directed on the revetted escarp of the inner rampart,—a system of defence which has since been generally adopted, and is most valuable when a secure communication can be kept up between the galleries and the work which they are intended to defend. After the great siege of Corfu by the Turks, and its successful defence by Schullemburg, some Dutch engineers who had been invited to Corfu by him, and had taken part in the defence, were employed in adding detached forts to the old Italian bastioned fronts. In these works the ruins of numerous examples of loopholed galleries and loopholed traverses may be observed; and they demonstrate that though Coehorn adapted in his writings his reliefs to the aquatic sites of Holland, he developed principles of defence which were equally applicable to other sites and other countries. It has been argued by Bousmard and others that an opening would be formed by shells through the couvre-face, and that the flanks of the bastions would be thereby exposed to the fire of the counter-batteries on the glacis; but it remains to be proved whether such an opening through an earthen mass could really be effected by the horizontal fire of shells; and the French translator of Zastrow, M. Neuens, captain of artillery, justly remarks that, "if shells fired horizontally into earthen works are so efficacious in destroying them, such shells must be a still more powerful instrument in the hands of the defenders for destroying the besiegers' batteries." Zastrow observes that, if we admit with Coehorn and others that, though the besieger may succeed in destroying a few feet of the parapet of the lower or outer face of the bastion, he would in vain, by firing shells horizontally into its mass, endeavor to lay open the counterscarp galleries, it must be admitted that he would, on mounting the low face, find himself in a most critical position, as all the defences, both direct and reverse, of the dry ditch, would remain uninjured, and be in full action against him. These dry or inner ditches, which facilitate the war of sorties, and the reverse or counterscarp galleries, are defensive arrangements of great merit, and may, by modification of profile, be adapted to any site; though the advantage dry ditches offer in such countries as Holland, where the besiegers cannot excavate in them without coming to water, cannot be expected in other sites, and must be made up for by stone pavements, or other contrivances likely to embarrass the besieger in his excavation. Coehorn assumes the plane of site to be 4 feet above the level of the water, and the dry ditch of his bastion is at its centre on the level of the water, so that a passage by sap becomes impossible, as the spade sinks at once into water; but near the escarp and counterscarp the ditches are 2½ feet below the plane of site, sloping on each side towards the central portion. The breadth of the dry ditch of the bastion is 98 feet, and that of the wet ditch before the salient 148 feet. All the slopes are at an angle of 45°. The whole breadth or thickness of the couvre-face, measured at the water level, is 52 feet, so as not to afford space for the besiegers' batteries, and its relief of construction only 12¼ feet. In the ravelin the relief of the low face is 10 feet, of the high face 18½ feet, and the height of its revetment 8 feet; in this work also the thickness of the low face would not afford space for batteries. The width of the dry ditch is the same as that of the bastion. These few details, with an examination of Plate IV., and of woodcut 69, will enable the student to comprehend the general principles of this great engineer; and it is rather by tracing out the ideas of a master mind, as exhibited in the *peculiarities* of his plans, than by studying the plans themselves as wholes, that the engineer will acquire practical knowledge which will enable him to vary his own projects, so that they may really be the best suited for the ground he is working upon.

Coehorn never restricted himself to the rules even of his own system. In fortifying Gröningen he was required to construct works on an eminence which commanded the town, and he adopted a trace towards the exterior of tenailles, the gorges of which were closed by small bastioned fronts constructed by walls which should be easily breached from the main works when the enemy had succeeded in gaining possession of any one of the intervening redans. By this curious combination of the tenaille and bastioned systems, Coehorn gave an undoubted proof of his superiority to the narrow prejudices which often prevent the adoption of the system best suited for the place.

METHODS OF BOUSMARD, CARNOT, CHASSELOUP, DUFOUR, NOIZET, HAXO, AND CHOUMARA.

It would be wrong to dismiss the subject of Bastioned Systems without at least some more reference to the works of these distinguished engineers than has been given in tracing the history of this subject. Bousmard makes the faces of his bastions as well as their flanks curvilinear, the former convex, and the latter concave outwards; but though by this arrangement the effect of ricochet fire may be diminished, the difficulty of defending the salient from the flanks is much increased. His great innovation, however, consisted in placing the ravelin and its redoubt in *advance* of the glacis of the body of the place, and forming in front of them a second or advanced covered-way, the object being to close the main ditch entirely, so that the besiegers' batteries should not be able to fire upon the body of the place through the ditch of the ravelin. The covered-way is made *en crémaillère*, and at each bend there is a sort of redoubt, or casemated traverse, not a simple hollow traverse loopholed, such as those in the detached works of Corfu. It has been objected to Bousmard's system that his advanced works would be speedily taken by turning the gorges both of the ravelin and its redoubt, but it should be remembered that the interior slope of both is replaced by a loopholed wall, being the front of an arched gallery running all round, so that the enemy could not remain within these works exposed to the fire from the galleries, as well as from the body of the place. Without advocating the precise form and disposition of the works recommended by Bousmard, it may be reasonably asserted that in every case of a powerful and well-appointed garrison, the defence will gain by assuming an active character beyond the precincts of the glacis.

As already observed, an unmerited indifference has been manifested by many engineers to the merits of Carnot, principally, it may be believed, from his exaggerated estimate of the effects of a vertical fire of small projectiles. Although he appealed to imagination rather than to calculation, when he assumed that by substituting 600 wrought iron balls, weighing each ¼ ℔, for the one shell of 150 ℔, with 6 mortars projecting 3600 balls, he might expect to put *hors de combat* 20 men at each discharge, or 2000 in 100 discharges, he was right in urging the importance of vertical fire. Carnot constructed his escarp without a revetment, but placed a detached loopholed wall in front of it with a chemin des rondes between, which is one essential feature of his system, the wall being constructed with arched niches in rear so as to shelter the men defending it; the loopholes are in two rows. He provided arched casemates for mortars on the gorge of his bastion in order to fire upon the capital, and the loopholed wall of an inner curtain, being continued along the retired flanks and in front of these mortar casemates, formed a complete inner retrenchment. Between the tenaille and the ravelin was an earthen cavalier, occupying the position of a redoubt in the ravelin, before the bastion's counterguard, so that the whole of the interior works were masked by these earthen envelopes. There is much ingenuity in these arrangements, and at least as full an appreciation of the value of earthen works as can be found in the writings of any modern writer. Carnot's leading principle, however, was, that a successful defence must depend on the active operations of the garrison, and that sorties therefore should be frequent and determined as soon as the enemy had approached close to the fortress. For this purpose he removed the revetment from the counterscarp, and formed it into an easy or countersloping glacis, to admit of the ready advance of the troops from the ditch upon the head of the besiegers' sap. He supposed that the overwhelming vertical fire of the 10 mortars in the mortar batteries in the gorges of his bastions would prevent the enemy from accumulating large covering parties in the trenches, and that he should therefore be able to fall upon the working parties and successfully delay the progress of the works. It has been shown that Carnot entertained an exaggerated view of the effects of vertical fire, but the idea of securing his mortars in casemated buildings is good, and has been adopted in the citadel of Ghent, and in several English works at Portsmouth and Plymouth; and it is impossible to study his works without profit.

Chasseloup (1754–1835), like Bousmard, placed his ravelin in advance of the glacis, and provided it with a small casemated keep, the flanks of which are pierced for two guns each. The tenaille is also provided with casemated flanks, and in front of it is a casemated redoubt or bastionette to supply the place of the ordinary ravelin, and to flank the salient portion of the face of the bastion, the general face being by him bent into two, so as to place the salient portion in line with the exterior side of the polygon, and thereby secure it from the ricochet fire. Casemated redoubts in the re-entering and salient places of arms, a defensive barrack, and a permanent entrenchment on the bastion are also included in his arrangements. De Sellon (*Mémorial de L'Ingénieur Militaire*) observes, "It would indeed be well to force the besieger to pass through two sieges, if the outworks pushed so far forward had higher scarps, and were not so easily turned at the gorge, but as the scarp is only 13 feet high, this possibility of attacking the works by the gorge without a previous descent into the ditch presents such serious inconveniences that it is surprising to observe that Bousmard and Chasseloup should have adopted so defective an arrangement." But notwithstanding this strong condemnation, it is at least doubtful whether such works are not the most suitable for a vigorous defence by a strong garrison, as they would enable the besieged to fall upon the assailants at the most critical moment of their attack with a powerful force; and it may be added that a skilful engineer would know how to throw many difficulties in the way of turning these advanced works, whilst the continance of the besiegers in them might be rendered both difficult and dangerous in the extreme.

The most remarkable feature in Dufour's modification of the modern system is, that one face of the redoubt in the re-entering place of arms is carried across the ditch, and connected with the coupure of the ravelin, so as completely to close the ditch and cover the face of the bastion from the fire of a battery on the glacis of the salient of the ravelin. Dufour also raised the salient of the ravelin into a high cavalier, so as to secure the faces from ricochet; and he proposed that the cavalier should be formed of gravel or small stones, so that the fire from the body of the place might, by scattering about these natural missiles, cause great damage to the enemy, when attempting to form a lodgment.

General Noizet has been already mentioned in connection with the Modern System, his modification of which is now the normal system adopted at the French military schools. Rejecting Dufour's mode of closing the ditch of the ravelin by carrying across it one face of the redoubt of the re-entering place of arms, he effected the same object by placing a massive mask between the coupure of the ravelin and the re-entering place of arms, from the inner escarp of which it is separated by a passage. The counterscarp of the bastion is carried continuously along the inner edge of the mask, whilst in front of it is a ditch which separates it from a demi-caponnière forming its counterscarp and covered-way, and a glacis sloping down the ravelin, of the ditch. The mask, the lunette redoubt in the ravelin, and the redoubt in the re-entering place of arms form a combined series of works of great efficiency for defence, which completely cover all but the salient portion of the face of the bastion. The flank of the bastion, as before observed, forms an angle of 80° with the line of defence, and the advantage taken of this in the citadel of Ghent in forming a most powerful intrenchment in the bastion, with a curtain as long as that of the main front, has also been pointed out.

General Haxo, one of the ablest engineers of modern times, did not publish his scheme of defence, nor did he reproduce it as a whole in the works he constructed, doubtless considering, as has been so frequently urged, that systems, so called, can only be looked upon as the exhibition of great principles, not as rigid rules for their application. His ravelin is made very prominent, and the salient is formed into a traverse, or mask, casemated and armed with artillery. Within the ravelin there is a redoubt, and within that a casemated caponnière or bastionette. The ditch of the ravelin is closed by continuing the counterscarp across it with a glacis slope into the ravelin ditch, and by this arrangement the ditch of the redoubt in the ravelin is also closed. The counterguards, the higher and the lower bastions, form almost three lines of defence, of which two, the outer and inner, are powerfully armed with artillery. The peculiar characteristic of the system is, that the parapet is thrown back, and made in its trace independent of the escarp, so that, whilst the latter retains the usual straight line, the parapet is broken into several portions not in the same line, and thus secured from the effects of ricochet—an arrangement of very great merit, and largely adopted in the Polygonal system. Haxo is probably better known to English engineers as the inventor of casemated batteries *à l'Haxo* than from his merits as an engineer, great as they were. These batteries are formed *in* the parapet, and though arched over with masonry, are covered with earth. They are open in the rear to the terreplein, and the openings in front for the guns are continued into embrasures formed in an extension of the parapet at these points beyond its ordinary retired position in Haxo's system. These batteries are thus secured from the effects of the enemy's fire, and when the embrasures are masked are equally hidden from his view, so that they may at any moment suddenly open a powerful and unexpected fire upon the besiegers. Being open in the rear, and connected together by arched openings between every pair, the circulation of air is sufficient to do away with the inconvenience from smoke, so generally complained of in casemated batteries. The batteries *à l'Haxo* have been used at Grenoble and Lyons, in the forts of Loyasse and Sainte-Foy, and in many English works. Their value has been much diminished by the range, penetration, and accuracy of modern rifled artillery.

The work of the commandant of engineers, M. Choumara, entitled *Mémoires sur la Fortification*, was published in 1847. In this treatise he maintains the principle that the direction of the parapet should be independent of that of the escarp, the latter being formed in straight lines, and considered permanent during the siege, whilst the former may be broken into several lines, and may be modified during the siege so as to facilitate the defence in any direction. Haxo had in his lessons or studies pointed out the importance of this principle, but Choumara was the first to advocate it in print. The castle of Naples exhibits an early example of the reverse operation, a new escarp having been built in front of the ancient round tower forts, so as to change them at the *base only* into bastions, whilst the upper portion of the towers became retired and independent parapets. Choumara, not relying on the bent trace of his retired parapet as a security from ricochet, proposed a traverse on the capital of his bastion, placed outside of the retired parapet, and 33 yards in length. This traverse, made 26 feet high and 78 feet wide at its base, would occupy less than two-thirds of the space of the twelve ordinary traverses required to secure from enfilade the faces of Choumara's bastions 164 yards in length, whilst it would cover not only the bastions but the flanks also. In addition to the traverse or mask on the capital, Choumara proposed high traverses, parallel to the flanks, at about 22 yards from the salients, which would not only secure the faces from enfilade, but would form secure or interior flanks, as cavalier flanks, commanding and firing over those in front. By making the cavalier flanks 98 yards long, and casemating them *à l'Haxo*, 15 guns might be placed in each, and the covered-way of the bastion attacked would be commanded by 30 guns in addition to those of the ordinary flanks, whilst the traverse of the capital would secure the flank cavaliers from ricochet. The last and most remarkable suggestion of Choumara is the proposal to widen his ditch to about 50 yards, and leaving a passage of communication of 16 yards round the base of the escarp, to form an interior glacis, sloping up from the base of the counterscarp towards the summit of the escarp, and having a base of 34 yards wide, thus constituting a continuous mask round the escarp. In respect to countermines, Choumara proposed to replace the great galleries, which are usually made 6 feet high and 3 feet wide, and which are the great arteries of a system of mines, by large vaulted galleries from 16 to 20 feet wide, pierced through the counterscarp, and continued as far as the third parallel. Six of these galleries were to be formed in each front, being placed about 55 yards apart, and connected together by minor transverse galleries or branches. Galleries of this magnitude would, in time of peace, be useful as stores, and in time of war would greatly facilitate the operations of the miner.

The details of military mining cannot be discussed here; but it may be stated that this subterranean warfare requires great skill on the part of both besieged and besieger. The besieged has the advantage of having had the main galleries of his countermines formed beforehand, but in spite of this a war of mines must generally be in favor of a besieger, since every explosion of the mines of the besieged, however destructive it may prove to the assailants, must destroy some portion of the works of defence, whilst every explosion of the besieger's mines must operate upon his enemy only. Starting, however, upon the assumption that a fortress, except in situations which render regular attack impossible, must ultimately fall, the real object of defence is to occupy the enemy for at least the time for which the fortress was designed to resist; and the destruction of the lodgment or of the battery of a besieger may materially protract the resistance of the intrenchment formed in a bastion, and thus enable the besieger to maintain his ground the longer.

The most simple form of mine, and that which may be most readily applied as an obstacle in the way of the assailant, is the fougasse. It consists of a chamber placed at the bottom of a pit about 12 feet deep. The charge is placed in a wooden box, and both the charge and size of the box may be thus estimated. When the line of least resistance, or shortest line drawn from the centre of the charge to the surface of the earth, which in this case is the depth of the pit, is 10 feet, a charge of 100 ℔ will produce an *entonnoir* or excavation, the radius of which is equal to the line of least resistance; and it has been ascertained that the volume of the excavation varies with the charge, the line of resistance and the resisting medium being the same, and that the volume varies also as the cubes of the lines of least resistance; hence, therefore, if W represent the weight of the charge, B the bulk of the *entonnoir* corresponding to 100 ℔ of powder and a line of resistance equal to 10 feet, and b that of the entonnoir corresponding to the charge W and the line of least resistance R, we have $100 : W :: B : b$; but as $B : b :: 10^3 : R^3$, we have $100 : W :: 10^3 : R^3$, and $W = \frac{1}{10} R^3$. Now let S = side of cubical box to contain the charge (55 ℔ of powder thrown loosely in, filling one cubic foot), and $S = \sqrt[3]{\frac{R^3}{10 \times 55}} = 0{\cdot}122\ R$, or nearly $\frac{1}{8}$ R in feet. The pits for fougasses vary generally from 8 to 12 feet in depth, and from 3 to 4 feet in width, being made square, and are revetted with planks when the earth is not firm enough to stand without support; and for this latter purpose gabions may be used of different diameters, so that the smaller may be slipped, through the larger, which have been previously fixed. The box for the powder is well tarred, and when intended to be left in the ground for some time, it should be covered with tarred canvas and put into another box, also tarred both inside and outside. The charge is ignited by Bickford's fuze, or by a saucisson or linen tube about an inch in diameter, filled with powder, and enclosed in a wooden case well tarred. The saucisson and its covering should be laid in a trench, sunk some feet in the earth, from the charge and pit to the place of ignition, in order to secure it from accidents as well as from the enemy's observation (see fig. 26, page 378, in which is also represented the mode whereby the fire is applied by what may be called the fire-box, the end of the trough and powder-hose being introduced into it). As for the thorough fulfilment of the object of a military mine the explosion should be "immediate," it is requisite to employ a contrivance for producing instantaneous ignition. This can be most readily and perfectly effected by employing electricity, and this is now as a rule employed in regular mining operations.

Experience has shown how little real injury the explosion of fougasses does to an assailant; but, as the moral effect of them is a degree of hesitation or irresolution often greater than that produced by musketry fire, and as they are easily extemporized, the fougasse may still be considered an obstacle of some value to the defence. Loaded shells packed in a case may be substituted for the ordinary charge, the case being formed with a horizontal partition, and the fuzes of the shells placed on the lower portion of the case, passing through holes in the partition, so as to be brought into connection with the firing-hose in the upper portion of the case. Another form is the stone fougasse, which is probably the most effectual of all. It is constructed thus. A conical pit is made in the earth about 5 or 6 feet deep, the axis being directed towards the enemy at an angle of 45° with the plane of construction, and at the bottom a charge of 50 ℔ of powder is placed in a well-tarred box. Over the box, and perpendicular to the axis of the cone, is fixed a lid on which as a platform are packed either stones or broken bricks, which, on explosion, are scattered over a space of about 60 by 70 yards. It should be laid down as a rule that facilities for discharging mines ought to be in every fortress, whether electric apparatus be used for the purpose, or openings be prepared in the works through which the powder-hose may be carried.

The last great modification proposed by Choumara is the extension of the exterior side, and the value of this can no longer be matter of doubt, now that the effective range of musketry has so much increased. The length of the line of defence may now be safely and advantageously fixed at between 400 and 600 yards, so that musketry and artillery can co-operate together efficiently. Chasseloup had, indeed, proposed to make his exterior side about 700 yards long, and he was no mere speculative engineer, for he had fortified with great skill Alessandria in Piedmont; but it must be borne in mind that no greater distance should be allowed for musketry than is compatible with distinct vision and a correct appreciation of distance; and further that the men intended to use the rifle in a fortress ought to be well trained for that object. The Gatling gun may in fitting positions be used with effect instead of musketry; it delivers a continuous stream of bullets at the rate of 400 per minute. The value of one Gatling is equal to 22 rifles, and nearly equal to two 9-pounders, and though it has a range of 1200 yards, it produces its best effect at short distances. In the defence of ditches its defect is that it cannot break or overturn scaling ladders.

German System of Defence.

Having traced the history of bastioned defence to the high state of perfection it attained, a summary of other systems will complete the subject. It has been shown that no sooner had the Italians invented the Bastioned System of defence than it found in every country persons who devoted themselves to the improvement of its details,—in France, Errard, Pagan, and Vauban; in the Netherlands, Freitag and Coehorn; and in Germany, Speckle, who was at least equal to any of the others. Germany, however justly it prided itself on Speckle, has gone back to Dürer, and has adopted from him the system of flanking defence, which depends on casemated galleries, and caponnières or casemated works placed across the ditches. Yet, notwithstanding this, it is remarkable that the Germans have taken much of their works from a French officer—the celebrated Marc René, Marquis de Montalembert, who in 1776 published his celebrated work, *Perpendicular Fortification, or an Essay on Several Methods of Fortifying a straight line, a triangle, a square, and all polygons of any number of sides, giving to their defence a perpendicular direction; also, Methods of improving Existing Defences and rendering them much stronger; also, Redoubts, Forts, and Field Intrenchments, of a New Construction*, in 11 quarto volumes, with 165 large plates,—a work which must be considered the source from which all the modern "inventions" in this branch of Fortification have been derived. Referring back to earlier German writers, it appears that Rimpler in 1673 proposed a system which is a combination of bastions with tenailles, and that Landsberg in 1712 proposed a purely tenaille system; but both these adhere to earthen ramparts and parapets, the first with revetments, the second without them, and their systems are little more than extensions of Field Fortification. But Montalembert, in his Tenaille System, replaces the simple revetment at the re-entering angles with casemated works in two stages, thus affording direct fire, both of artillery and musketry, for the defence of the ditches and faces of the redans, the remaining portion of the trace being occupied by an earthen couvre-face work, with a detached loopholed gallery in front of it, evidently the prototype of Carnot's detached revetment. The re-entering casemates are calculated to hold 24 guns in two tiers. Behind the couvre-face is the body of the place of the redan, being also fronted by a casemated gallery, and separated from the couvre-face by an inner wet-ditch. In this system, then, the defence by musketry as well as by artillery is from two levels, the upper at a moderate height above the bottom of the ditch, and not, as in the old Italian systems, at the high level of the crest of the parapet. At the gorge of each redan is placed a formidable casemated tower; whilst in front of the main ditch there is a general couvre-face provided with casemated galleries, a second or advanced ditch, places of arms in front of the re-entering angles, a covered-way, and a glacis.

The Polygonal System may, however, be considered as springing directly from Dürer's work of the same name, only in this system the simple earthen ramparts of Dürer are replaced by a combination of casemated towers, casemated galleries, and earthen couvre faces. In Dürer's polygon the sides were straight or unbroken, but in Montalembert's the centre was thrown back and formed into an Italian bastioned trace, the faces flanking the faces of the caponnière. In forts which formed a triangle or square Montalembert was rich in resources, though the massive casemated tower, casemated galleries, and earthen couvre-faces were the essential elements of all. In France, the views of Montalembert have never been received with enthusiasm, though Cherbourg is fortified in conformity to them, and it was even alleged that the corps du genie was indisposed to receive instruction from an officer of another arm; but it is more reasonable to suppose that the cherished name of Vauban has induced its officers to direct their attention rather to the improvement of the Bastioned System, which they have certainly carried to perfection, than to the development of a system depending on such different principles. In Germany, on the contrary, Speckle is less known than Vauban, and though probably a thought of Dürer may not have entered into the question, Montalembert's Systems, founded upon some of Dürer's principles, have been adopted, and may be studied in the works of defence of Coblentz. In all such works masonry defences or casemated buildings assume a character of the highest importance, but it should not be forgotten that masonry can never resist the effects of a *concentrated* fire of heavy guns, and can be considered safe only when protected by earthen masks or couvre-faces. The Maximilian towers of the defences of Lintz are no longer approved by modern engineers, and in closing the harbor of Sebastopol against approach by sinking a large portion of their own fleet, the Russians exhibited their distrust of masonry defences when opposed to ships. And this distrust is not to be wondered at when it is remembered that, to bring the guns forward enough to afford them lateral training, the walls of casemated batteries must be cut into, and greatly weakened. This great defect of masonry defences, and the evils of smoke in close casemates, are well known to engineers. In the earliest periods of Italian fortification, the necessity of increasing the active power of the flanks beyond that afforded by their length was strongly felt; and retired flanks, rising one above the other, were adopted, as well as casemated flanks admitting two or more tiers of guns, thus obtaining, as in Montalembert's System, a greater number of guns by extending the battery vertically. At first sight this appears an obvious mode of acquiring a superiority over the attack, in which the batteries can only be extended laterally, but in practice the retired flanks were soon found to be untenable, while the front flanks were complete shell-traps, and the casemates were practically useless from the difficulty of clearing the smoke from them. The systems of Montalembert partake of the same defects; and however imposing the appearance of several successive tiers of guns may be, it should be remembered that, covered by a mask, they can only be partially used when the enemy is at a considerable distance, and that exposed to view they can be easily destroyed at 2500 yards by the guns of attack of the calibres now in use. Several writers have proposed systems based upon principles similar to those of Montalembert, but it is perhaps sufficient here to mention the work of Don Jose Herrera Garcia (*Teoria Analytica de la Fortificacion Permanente*), as it is unquestionably the most remarkable development of the tower system of defence. Garcia proposes several successive lines of massive casemated buildings or towers, of an egg-shape, connected together with casemated curtains. The towers are surmounted by parapets, which at the ends next the enemy are broken into a series of smaller curves, and are retired or independent of the exterior wall or scarp. As each of these towers is defensible of itself, the work of forcing a way through three lines of them would be most formidable, but the expense of such a system would be enormous.

The system of the Swedish general Virgin belongs to the bastioned systems, but it is mentioned here in contrast to Garcia's, as it disperses in the defences separate bastioned forts,—of a form somewhat approaching to Rimpler's, and covered by outworks so arranged as to secure the inner works from injury until the enemy has effected his lodgment upon them. These forts are surrounded on all sides by ditches, and connected together by secure communications. Ingenious as Virgin's system is, it is manifest that though the loss of one fort would not insure the fall of the others, it would at least render all the interior space inclosed by the line of forts untenable, and place the town, the arsenal, or other public buildings, at the mercy of the besiegers. This may be said of all detached forts, and it must be again laid down as a maxim that the ultimate value of such forts, as a means of securing an important object, depends on an inner line of defence of a nature to resist any sudden attack or *coup-de-main*. Detached forts may be, for the purpose of keeping an enemy at a distance, more effectual than a simple continuous line, but they cease to be of use if an enemy can pass them and attack a defective interior line behind, incapable of resisting a *coup-de-main*.

It has been well stated by the French translator of Zastrow, that the reduction of a place may be considered as a certain amount of work to be performed, the magnitude of which depends on various elements, amongst which the disposition and nature of the works constitute the most important; and that the attack has to perform this work in a certain time, and with certain means, amongst which the principal elements are the quantity of heavy artillery, and the nature of the ground over which the approaches must be carried. When, therefore, it is said that a work fortified on Vauban's first system would fall on the twenty-eighth day,—on Cormontaigne's, with a cavalier entrenchment in the bastion, on the thirty-first,—it must be remembered that this implies the possibility of complete investment, and of steadily advancing the approaches over soil easily worked by the sapper; but that if the investment be incomplete, if the ground be rocky, and every inch have to be gained by hard and incessant toil, protracting the time during which the sapper is uncovered, and therefore greatly adding to the daily losses in the trenches, such periods may readily be extended to twice or three times their ordinary length.

Intrenched Camps.

It would not be proper to leave the subject without a brief description of intrenched camps, especially as they have an important bearing upon the defence of capitals, with which this article closes.

An intrenched camp is a position, prepared beforehand, in which an inferior army rests in security from the attack of a superior army, and from which it may operate upon the communications of such superior army, or in which a beaten army takes refuge for the purpose of reorganization. The position selected for an intrenched camp is usually around the capital, or around an important city, or on an important line of communication. The position should therefore contain sufficient space to receive the army for which it is constructed, to contain ample supplies of all kinds, and to keep an enemy beyond bombarding distance not only from the city, but from the camping-grounds within it. An intrenched camp should consist of a chain of independent forts, with, wherever practicable, a strong inner work; the forts should be as large as possible, and disposed in a right or slightly convex line. No fort should have undue prominence over the others, as such a fort would be a source of weakness, inasmuch as it might be attacked by itself, and being further removed from the centre of defensive operations would be more difficult to succor. The camp should be traversed by free and easy communications; and if it have an interior work, that work should command the whole of the interior. It should also possess facilities for passing rapidly from the defensive to the offensive, and sufficient interior space for the execution of such manœuvres as are necessary for the defence of the position.

Fortification of Capitals.

Whether capitals, as capitals, should be fortified has given rise to much difference of opinion; but all authorities are agreed that the capitals of highly centralized countries must be fortified. In such countries the principal resources of the state, both public and private, are collected in the capital; in it is placed the centre of government, and from it administration and organization radiate. Such a capital is truly the heart of the nation; a deadly blow to it stops the national circulation, and national paralysis may and will probably follow. Take, for example, England, perhaps the most highly centralized of countries. Can it be doubted that an enemy in possession of London could exact what terms he pleased? Upon this point the commissioners appointed to consider the defences of the United Kingdom say,—"There can be no doubt that the main object of an enemy invading the country would be to push for the capital, in the hope that, if he succeeded in obtaining command of it, such a disaster would result in our buying him off upon any terms he might think it expedient to exact." This was written in 1860, but within eleven years its general truthfulness was thoroughly established by the fall of Paris, when the exactions of the Germans were only limited by the ability of the French to comply with them. It is then scarcely too much to say that the fall of London would result in the downfall of England. Speaking of the general confusion and ruin which the presence of a hostile army on British soil must produce, Lord Overstone said: "The occupation of London by an invading army! . . . I cannot contemplate or trace to its consequences such a supposition." And he might well say so; not England only, but the cause of civilization throughout the world would be shattered by such an occupation.

At a time when capitals were by no means the *national centres* which they have since become, owing to the development of the means of locomotion, and to the discoveries of electrical science, Napoleon said that a great capital is the native place of the flower of the nation, the central point of public opinion, and the general dépôt; and he added that it is the greatest of absurdities to leave so important a place destitute of immediate defence.

How then should a capital be fortified? The answer is, that it should be so fortified that it may be safe from bombardment and from blockade, and that its defences may be beyond the control of its inhabitants.

These objects may be attained by two methods,—first by constructing a circle of detached forts round the capital, and at such a distance in advance of it as shall render investment impossible, or, secondly, by forming a cordon of intrenched camps far in advance of the capital, making at the same time such arrangements as shall facilitate the rapid concentration of troops in any of them.

With respect to these two methods there is much difference of opinion, and eminent military authorities may be cited in support of one or the other according to the bias of the writer. Nevertheless it may be safely asserted that the value of either is dependent upon the number and quality of the troops available for its service. If the troops be few, or insufficiently trained and poor in quality, then it would be proper to have recourse to a system of detached forts round and not far in advance of the capital, and so disposed that they may, in a measure at least, be manned by local auxiliary levies. If, on the other hand, the troops be fully equipped, thoroughly trained and disciplined, with high power of manœuvring, then, even though inferior in number, it may be advisable to have recourse to a cordon of intrenched camps.

Generally, if circumstances admit of its adoption, the second method is the better, especially if the camps are disposed at such intervals that an enemy in force cannot pass between them, and at such distance from the capital that, if driven out of them, there is still time left to fall back and take up some inner position upon which to deliver a decisive battle. The capital though well covered by the camps, would take no part in the active defence, and would not be attacked after the fall of one of them, while the occupants of the camps could fight with no apprehension of the populace rising in their rear, a danger to be apprehended from the most patient of people, as they become pinched by the privations and miseries of a siege.

In practice it will almost always happen that a combination of the two methods will be adopted; but whatever method be adopted it will generally be inadvisable to surround the capital, more especially if large, with a close enceinte. If, however, it have such an enceinte, the works of which the enceinte is composed should be provided with strong interior defence. In all large cities there is a considerable cosmopolitan and vagrant element, possessed of no property, and having no interest in the maintenance of order, whose contact with the soldiery may be attended with deplorable results, inasmuch as it must tend to lessen the bands of discipline, to destroy the habits of obedience, and to weaken those feelings of devotion and self-restraint which are more than ever necessary under the privations of a close siege.

Against this view it may be urged that the enceinte constructed round Paris in 1840 prevented its falling into the hands of the Prussians after the battle of Chatillon. This may be true; but in estimating the value of this enceinte it should be borne in mind that 236,000 Prussians were sufficient to shut up in it, and eventually reduce by famine, a garrison of 300,000 men, and it is certain that the absence of interior defences in that enceinte permitted a mere handful of communists to make themselves masters of Paris and its fortifications, and to force back the regular troops upon Versailles. Generally, however, the rapid growth of the population in very large cities precludes a close enceinte. Indeed the enormous extent of very large capitals, and the very long range of present artillery, render the fortification of them so costly that, in elaborating any scheme for their defence, cost must enter largely into calculation, and must materially modify theoretical and scientific conclusions.

But however elaborately the capital may be fortified, the full effect of the expenditure upon its fortifications is not obtained unless other strong places are formed in appropriate positions in relation to it; for if the capital only be fortified, defence will cease with its fall. It is asserted upon the authority of official documents that the French would not have yielded to the conditions exacted by the conquerors of Paris in 1871, if there had remained to them strong defensive positions such as Orleans, Tours, and Bourges, upon which the armies, poor in quality as they were, of Chanzy, Faidherbe, and Bourbaki could have operated. In fact, if the capital only be fortified, the object of invasion will be limited to it, and the task of the invader will be much simplified, for he will have little fear of his communications, and will be able to make his circle of investment of such strength as seems best to him. And when once the investment is completed, it is matter of great difficulty for the inclosed army, even if superior in numbers, to break out. Its best chance of breaking out is during the first days of the investment, particularly at the period when the enemy commences to extend himself round the circle of investment, and in so doing, presents his flank to it. After the investment is complete, the inclosed army is in a bad position for delivering an attack, as it must advance and deploy under concentric fire playing upon it in front and in flank. The difficulties of such an attack are exemplified in the French attack during the siege of Paris upon the 5th German corps between St. Cloud and Buzenval, when 84,000 French attacking from an interior position were defeated with a loss of 6000 men by 20,000 Germans with a loss of only 646.

The advantage of other strong places was shown when 180,000 Germans were detained for a time before Metz. But Metz and Strasburg were so far from Paris that they had scarcely any relation to it. Moreover, they lay close to the frontier; and as here there were no intermediate strong places they were rapidly isolated, and when they fell into the invader's hands proved of great service to him. The absence of an intermediate line of defence probably led to the disaster of Sedan and the fatal investment of Paris, while on the other hand the fortresses on the northern frontier, out of date and ill adapted as they were to meet the appliances of modern warfare, enabled Faidherbe's raw levies to hold their ground as successfully as they did.

If one truth be taught more clearly than another by the Franco-German war, it is the advantage, nay, the absolute necessity, of fortifying, but of properly fortifying, the capital of a highly centralized country. When we consider France deploring the flower of her youth sacrificed, the destruction wrought in her capital, and the spoliation of two of her fairest provinces, and mulcted in a money payment of £200,000,000 with an addition of £170,000,000 more to her debt,—can we avoid the conclusion that no sum spent upon fortifications would have been too large if it had preserved her from such calamities? All that Paris is to France, London is, and more, to the British empire. Paris is rich and populous; London is richer and far more populous. Paris was a tempting prize to an invader; London is more tempting and more accessible. The resources of France in her soil and in her climate are great, and her children are so thrifty that she is self-dependent; but it is far otherwise with Great Britain. She depends upon foreign countries for half the necessaries of life, and the commerce by which her supplies of food are gathered is mainly centred in her capital. France, as we see, has already recovered from the fall of her capital; but the fall of England's might be without a rise, for it might be attended with a collapse of commerce from which there should be no recovery. Yet notwithstanding the pressure of unheard-of ills, and with the regeneration of her army straining her resources heavily, France finds means to spend £4,000,000 upon the fortifications of Paris. With this example before her eyes shall Great Britain in the full tide of prosperity do less for London? (J. E. P.—C. H. N.)

FORTROSE, a royal and parliamentary burgh of Scotland, county of Ross; is situated on the N. side of the Moray Firth, nearly opposite Fort-George, from which it is 2½ miles distant, and with which it has regular ferry communication. It was made an episcopal see in the 12th century by David I., but only a small portion of the cathedral now remains. It has a handsome Episcopal chapel and academy, and a good harbor, with a depth of 14 feet water at high tide. On account of the romantic scenery of the neighborhood, the town possesses considerable attractions as a watering place. The parish church is at Rosemarkie, about a mile eastward. Sir James Mackintosh received his early education at Fortrose. This borough unites with Inverness, Forres, and Nairn in returning one member to parliament. The population of the parliamentary burgh (which includes Rosemarkie) was 1017 in 1871.

FORTUNA, the Latin goddess of Fortune, answering to the Greek Tyche, Τύχη. This deity was of far more importance in Italy than among the Greeks, the special characteristic of the Italian or Latin religion being the worship of abstract qualities. At Rome the culture of Fortune was said to have been introduced and established by Ancus Marcius and Servius Tullius; and her temples were especially honored at Antium and Præneste, where her oracular responses were in the highest repute. She was worshipped under a vast variety of epithets, the most prominent being *virilis*, as denoting the power which secured to women the affections of their husbands; *muliebris*, a name connected with the legend which made the women of Rome prevail over the resolution of Coriolanus; *publica, privata, conservatrix, primigenia*, etc. We hear also of a Fortuna Mammosa, corresponding to the many-breasted Artemis of Ephesus, and to the Teutonic Ciza, Zizi, whose name Tacitus in his *Germania*, c. 9, seems to have confounded with that of the Egyptian Isis.

FORTUNATE ISLANDS. See CANARY ISLANDS.

FORTUNATUS, the legendary hero of one of the most popular of European chap-books. He was a native, says the story, of Famagosta in Cyprus, and after many strange adventures and vicissitudes fell in with the goddess of Fortune in a wild forest, and received from her a purse which was continually replenished as often as he drew from its stores. With this he wandered through many a city and kingdom, and at last arrived at Cairo as a guest of the sultan. Among the treasures which the sultan showed him was an old napless hat which had the curious power of transporting its wearer to any place where he desired to be. Of this he feloniously possessed himself, and returned home to Cyprus, where he lived in the free gratification of all his fancies and desires. On his death he left his purse and his hat to his sons Ampedo and Andelosia; but instead of harmoniously putting them to use, they were jealous of each other, and by their recklessness and folly soon landed themselves in the depths of misery. The *motif* of the story is very obvious: in the words of the preface, the reader should learn that all men should desire reason and wisdom before all the treasures of the world. In its full form the history of Fortunatus is a brisk narrative of considerable length, occupying in Simrock's *Die Deutschen Volksbücher*, vol. iii., upwards of 158 pages. The scene is being continually shifted—from Cyprus to Flanders, from Flanders to London, from London to France; and a large number of secondary characters appear from time to time on the stage. The general features of the style and the allusions seem to indicate a comparatively modern date for the authorship; but the nucleus of the legend can be traced back to a much earlier period. The stories of Jonathas and the three jewels in the *Gesta Romanorum*, of the emperor Frederick and the three precious stones in the *Cento Novelle Antiche*, of the Mazin of Khorassan in the *Thousand and One Nights*, and the flying scaffold in the *Bahar Danush*, have all a certain similarity. The earliest known edition of the German text of Fortunatus appeared at Augsburg in 1509, and the modern German investigators are disposed to regard this as the original form. Innumerable rifacimentos have been made in French, Italian, Dutch, English, etc., and cheap editions are still common enough on the bookstalls. The story was dramatized by Hans Sachs in 1553, and by Thomas Dekker in 1600; and the latter comedy appeared in a German translation in *Englische Komödien und Tragödien*, 1620. Tieck has utilized the legend in his *Phantasus*, and Chamisso in his *Peter Schlemihl;* and Uhland has left an unfinished narrative poem entitled "Fortunatus and his Sons."

See Dr. Fr. W. V. Schmidt's *Fortunatus und seine Söhne, eine Zauber-Tragödie, von Thomas Decker, mit einem, Anhang*, etc. Berlin, 1819; Görres, *Die deutsche Volksbücher*, 1807.

FORTUNATUS, VENANTIUS HONORIUS CLEMENTIANUS, bishop of Poitiers, and the chief Latin poet of his time, was born near Ceneda in Treviso, in 530. He studied at Milan and Ravenna, with the special object of excelling as a rhetorician and poet, and in 565 he journeyed to France, where he was received with much favor at the court of Sigbert, king of Austrasia, whose marriage with Brunhild he celebrated in an *epithalamium*. After remaining a year or two at the court of Sigbert, he travelled in various parts of France, visiting persons of distinction, and composing short pieces of poetry on any subject that occurred to him. At Poitiers he visited Queen Radegonda, who lived there in retirement, and she induced him to prolong his stay in the city indefinitely. Here he also enjoyed the friendship of the famous Gregory, bishop of Tours, and other eminent ecclesiastics. He was elected bishop of Poitiers in 599, and died about 609. The later poems of Fortunatus were collected in 11 books, and consist of hymns, epitaphs, poetical epistles, and verses in honor of his patroness Radegonda and her sister Agnes, the abbess of a nunnery at Poitiers. He also wrote a large poem in 4 books in honor of St. Martin, and several lives of the saints in prose. His prose is stiff and mechanical, but most of his poetry has an easy rhythmical flow.

An edition of the works of Fortunatus was published by Ch. Brower at Fulda in 1603, 2d edition at Mayence in 1617. The best edition is that of M. A. Luschi, Rome, 1785, which was afterwards reprinted in Migne's *Patrologiæ cursus completus*, vol. 88.

FORT WAYNE, or, as it is sometimes called, "Summit City," a city of the United States, at the head of Allen county, Indiana, situated 751 miles W. of New York and 102 N.E. of Indianapolis, at the junction of the St. Joseph and the St. Mary, which form what is known as the Maumee River. The Wabash and Erie canal passes through the town, and no fewer than eight railway lines branch out from it in various directions. Besides the extensive works maintained by several of the railway companies for the building of carriages, etc., there are a number of engineering establishments, planing mills, flour mills, and tanneries, sash and door works, and a woollen factory. The churches are twenty-seven in all; the educational institutions comprise a high school, a normal school, a Methodist college (founded in 1846), the Concordia Lutheran college (founded in 1850), and two public libraries; and among the other public buildings may be mentioned the court-house, the county jail, the city hospital, and the orphans' home. Interior communication is facilitated by six miles of tramway lines. In the early part of the 18th century the French established a trading post on the site of the present city, which took its name, however, from a fort erected in 1794 by General Wayne. The town was laid out in 1825, but did not become of much importance till the opening of the Wabash and Erie canal in 1840. In that year it attained the rank of a city, though its inhabitants numbered only 2080. By 1850 they had increased to 4282, by 1860 to 10,388, and by 1870 to 17,718.

FORUM, the word employed by the Romans to denote any open place in which men congregated for the transaction of mercantile or political business. It is connected with *foris*, and the same root also appears in the Greek *θύρα*, the Sanskrit *dvâra*, and the English *door*. In the laws of the Twelve Tables it occurs as equivalent to the vestibule of a tomb (Cic., *De Leg.*, ii. 24); in a Roman camp the forum was an open place immediately beside the prætorium; and perhaps the word may at one time have been applied generally to the space in front of any public building or gateway. In the city itself, however, during the period of the early history, forum was almost a proper name, denoting the flat and formerly marshy space between the Palatine and Capitoline hills, which probably even at the regal period had afforded the accommodation necessary for such public meetings as could not be held within the area Capitolina (see ROME). During the days of the republic the city had only one forum, but under the empire a considerable number both of fora civilia and of fora venalia came into existence. To the former class belonged those of Julius and of Augustus, and also that of Nerva, which was sometimes called Transitorium or Pervium. Of the latter order the most important were the Olitorium, Piscatorium, and Boarium. Those called after Trajan, Sallust, Diocletian, and Aurelian were probably intended merely as public lounges. The word forum frequently appears in the names of Roman market towns; as, for example, in Appii Forum, Forum Julii (Frejus), Forum Livii (Forlì), Forum Sempronii (Fossombrone). The fora were distinguished from mere vici by the possession of a municipal organization, which, however, was less complete than that of a prefecture. In legal phraseology, which distinguishes the forum commune from the forum privilegiatum, and the forum generale from the forum speciale, the word is practically equivalent to our "court" or "jurisdiction."

FOSBROKE, Thomas Dudley (1770–1842), an English antiquary, was born in London, and was called Dudley after a cousin of that name, esquire of Lebotwood Hall in Shropshire. Fosbroke has given accounts of himself and family in most of his works, accompanied with lists and statements of facts supporting possible alliances. He was of an old Staffordshire family, no individual of which ever attained to any particular eminence. It had long been the custom in this family that one of the sons should enter the church, and the dying wish of the father in this case was that his son should take holy orders. Going to St. Paul's school at nine years of age, Fosbroke took in 1785 a Tesdale scholarship at Pembroke College, Oxford, and graduated as M.A. in 1792. In that year he took also deacon's orders and settled in the curacy of Horsley in Gloucestershire, where he remained till 1810, taking priest's orders in 1794. In 1810 Fosbroke removed to Walford in Herefordshire, and passed there the remainder of his life, as curate till 1830, and afterwards as vicar of the parish. In 1796 he published the *Economy of Monastic Life*, which is, according to his own account, "a poem in Spenserian measure and style, written upon Darwin's doctrine of using only precise ideas of picturesque effect, chiefly founded on the sense of vision." Whatever all that may mean the poem is entirely unreadable, although "the reviews were favorable." This with other poetical attempts of Fosbroke's was reprinted at the end of the third edition (1843) of his next book, the *British Monachism*, 2 vols. 8vo, 1802,—a compilation from manuscripts in the British Museum and Bodleian libraries, with subordinate use of printed authorities, of facts relating to the manners and customs of the monks and nuns of England, which was very favorably received. In the second and third editions this work was much enlarged. In 1799 Fosbroke had been elected fellow of the Society of Antiquaries, and resolved to devote himself to the study of archæology. *British Monachism*, the first result of his studies, was always his favorite work. In 1807 was published by subscription his *Abstracts and Records of Manuscripts respecting the County of Gloucester*, after which he entered into an engagement with Sir Richard Philips for several important works, including an encyclopædia of antiquities; but owing to the commercial failure of that enterprising gentleman in 1810, these plans fell through. In 1814 he published an *Abridgment of Whitby's Commentary on the New Testament;* in 1819 a *History of the City of Gloucester*, from new materials; in 1818 *The Wye Tour;* and in 1821 its companion, *Ariconensia, or Archæological Sketches of Ross and Archenfeld, illustrative of the Campaigns of Caractacus and the Station Ariconium.* In 1821 also was issued his edition of the *Berkeley Manuscripts*, with a history of the castle and town of Berkeley and a life of Jenner. The work for which Fosbroke is best remembered, the *Encyclopædia of Antiquities*, was first published in 1824, 2 vols. 4to; a second enlarged edition appeared in 1840. This work, though perhaps open to objection on account of a certain incoherence and disproportion, embodies the results of a large amount of reading among manuscript and other obscure sources. A sequel to this, called *Foreign Topography*, was published in 1828. His other works are *A Picturesque and Topographical Account of Cheltenham and its Vicinity* (1826); *The Tourist's Grammar, or Rules relating to the Scenery and Antiquities incident to Travellers* (1826); "A Treatise on the Arts, etc., of the Greeks and Romans" (1833), for Lardner's *Cabinet Cyclopædia;* "Extracts from Manuscripts relating to English History," and "Illustrations of the Constitution of our Ancient Parliaments," contributed to the *Transactions of the Royal Society of Literature*, of which body Fosbroke was elected honorary associate in 1827. He also made extensive researches into the pedigree and history of the Clinton family at the desire of the duke of Newcastle, in the possession of whom three large folio volumes of his MSS. now remain. Fosbroke was in the early part of this century a regular contributor to the *Gentleman's Magazine* of both original articles and reviews. Although without pretension to style as an author or judgment as a critic of antiquities, he was a student and writer of good aims; and despite a recurring tendency to whine at his fate in prefaces, his works can be read with some pleasure and profit. He died at Walford on the 1st January, 1842.

FOSCARI, Francesco (d. 1457), doge of Venice, was born probably about 1372. He was of a patrician family, early displayed an ambitious temper, and rose to high honors in the state. He was already a member of the great council, when in 1412 he was named one of the guardians of the young marquis of Mantua; and by his wise administration he won the gratitude both of his ward and of the people. In 1421, being then one of the *procuratori* of St. Mark, he zealously advocated war on behalf of Florence against the powerful duke of Milan. The reigning doge, Tommaso Mocenigo, was opposed to this policy; and when dying two years later, he warned his countrymen against electing Foscari as his successor, on the ground that he would plunge Venice into a disastrous war. The warning, however, was ineffectual; for after six days' deliberations, with nine scrutinies, Foscari was elected doge. His success was ensured by bribery on a large scale. In proclaiming his election, a significant omission was made from the customary formula, the words which recognized the popular share in the appointment being entirely dropped. The ancient formula was never again used. Florence continued to press for an alliance with Venice against Milan, and the negotiations were still going on when, in 1425, the famous Carmagnola, who had for eight years commanded the Milanese armies and made many conquests for his master, the duke Filippo Maria, arrived at Venice, a fugitive in disgrace. His influence gave the decisive impulse to the hesitating Venetians; and in January, 1426, a league was formed and war was declared against Milan, Carmagnola being appointed captain-general of the army of Venice. Brescia and Cremona were conquered for Venice, and the war was carried on with alternation of success and failure and intervals of peace till 1433, when Foscari consented to treat, and peace was signed at Ferrara. The doge then offered his abdication, but the senate refused to accept it. After another troublous period of nine years he renewed his proposal, when the senate not only refused as before, but exacted from him an oath that he would retain his sovereignty for life. To the toils and harassments of office and of war were added, during his remaining years, great family sorrows. He had four sons, three of whom were already dead. The fourth, Giacopo, connected himself by marriage in 1441 with the noble house of Contarini. Within four years of this event, Giacopo was denounced to the council of ten as having received presents from several foreign princes, one of the highest offences a noble could be guilty of. He was tortured in the presence of his father, and, having made a confession, was condemned to perpetual banishment to Napoli di Romania. The aged doge was compelled to pronounce the sentence on his son. Five years later (1450), the assassination of Hermolas Donati, one of the ten, took place at Venice, and suspicion fastened on the banished Giacopo, one of whose servants was seen at Venice at the time. The servant was arrested and repeatedly tortured, but no confession was wrung from him. Giacopo was then recalled from his place of exile, was again put on the rack in his father's presence, and although not a particle of evidence was to be had against him, he was condemned and banished to the isle of Candia. The real assassin was afterwards discovered, but the sentence against Giacopo was unrevoked. He was forbidden all communication with his wife and family, and life became an intolerable burden. In 1456 he wrote a request to the duke of Milan to intercede for him, and purposely left the letter open and discoverable. It was presented to the council of ten, and his end was gained, for he was immediately summoned to his native city to answer the charge of seeking foreign intercession. For the third time he was examined before his father, the doge. This time he confessed the crime of which he was accused. He was nevertheless put on the rack no less than thirty times with a view to extort a declaration of innocence, and this in his father's presence. But it was in vain, and the wretched man, torn and dislocated, was once more banished. He died shortly afterwards in Candia. The father henceforth remained in retirement, incapable of discharging the duties of his office. At length through the intrigues of Giacopo Loredano, a member of a family which had an hereditary feud with the Foscari, the council were induced to request his abdication. He pleaded his oath not to resign which they had compelled him to take; but they discharged him of it, declared the dogate vacant, gave him a pension, and expelled him from the palace (1457). They wished him to withdraw by a private staircase to escape the notice of the people, but this he firmly refused to do. Supported by his brother, he slowly descended the giants' stairs, and with the parting words—"My services brought me within these walls, the malice of my enemies drives me away,"—he took his leave (Oct. 25). A decree of the council prohibited any mention of his name, under penalty of death, thus suppressing all expression of popular regret. On the 30th of the same month his successor was elected, and the announcement of the election by the bell of the campanile agitated him so violently that he ruptured a blood-vessel and died in a few hours. One year after his death it was declared that the council of ten had exceeded their authority. The melancholy story of the Foscari furnished Byron with a theme for a tragedy, and is narrated by Rogers in one section of his *Italy*—the two poems being published within a few days of each other (1821).

FOSCARINI, MARCO (1696–1763), doge of Venice, historian, was born January 30, 1696. He was of an illustrious patrician family, and his fine character and superior abilities opened for him at an early age the path of public service and advancement. He rose through the regular stages of office to be *cavaliere* and *procuratore* of St. Mark, and was nominated historiographer of the republic. It was intended that he should take up and continue the story from the point to which it had been brought by Michele Foscarini and the senator Garzoni. But his services were turned into another channel. He was entrusted successively with important embassies to the courts of Vienna, Rome, and Turin, his task being to maintain the strict neutrality of Venice in the wars between the French and the Imperialists. During these embassies he drew up, after the manner of Venetian ambassadors, reports of his negotiations and proceedings, and also of his observations of affairs at the various courts. Thus removed from Venice and from access to the public archives, from which the materials of his projected history must have been drawn, it was impossible for him to write it. He undertook, however, to collect materials for a literary history of his country, proposing to treat the subject under two heads, first the useful (or scientific) literature, and secondly the more strictly literary works. In 1752 appeared the first volume of the first division, in four books; and this remains a fragment, no more having been published. Foscarini after his return from Turin was placed at the head of the university of Padua, in the conduct of which he brought about some important reforms. In 1762 he rose to the highest dignity of the state, being elected to succeed Francesco Loredano as doge. Among the other literary remains of Foscarini are an oration on the administration of Dalmatia, not published till 1831; an account of the imperial court and administration, published in 1843; a report on his Sardinian embassy, etc.; besides several unpublished pieces. He held the dogate for ten months only, dying on the 31st of March, 1763. He left a large collection of books and manuscripts, the latter now forming part of the Imperial Library, Vienna.

FOSCARINI, MICHELE (1632–1692), Venetian historian, was born in 1632. By the deaths of his father and mother he became head of his house at the age of nineteen. Of patrician rank, he entered upon official life in 1657, and after filling various posts became in 1662 one of the *avogadori* of the republic. Two years later he was appointed governor of Corfu with the title of *provveditore* and captain. Returning to Venice in 1668, he was selected to fill some of the most honorable offices of the republic. On the death of Battista Nani in 1678, Foscarini was called to succeed him as historiographer of Venice. He continued the history begun by Bembo, and carried on by other writers, from 1669 to 1690, but had not quite completed his work when he died suddenly, March 31, 1692. The *Istoria della Repubblica Veneta* was published by his brother Sebastiani in 1696, and has been several times reprinted. Foscarini was author also of two *Novelle* written in his youth; and he annotated Caramella's *Museum illustriorum Poetarum* (1653).

FOSCOLO, UGO (1778–1827), the Italian writer who next to Alfieri has most contributed to free the literature of his country from the pedantries and affectations of the 17th and 18th centuries, was born at Zante on the 26th of January, 1778. On the death of his father, a physician at Spalatro, in Dalmatia, the family removed to Venice, and in the university of Padua Foscolo prosecuted the studies begun in the Dalmatian grammar school. The fact that amongst his Paduan masters was the Abbé Cesarotti, whose version of Ossian had made that work highly popular in Italy, was not without influence on Foscolo's literary tastes, and his early knowledge of modern facilitated his studies in ancient Greek. His literary ambition revealed itself by the appearance in 1797 of his tragedy *Tieste*—a production which obtained a certain degree of success. Foscolo, who from causes not clearly explained, had changed his Christian name Niccolo to that of Ugo, now began to take an active part in the stormy political discussions which the fall of the republic of Venice had provoked. He was a prominent member of the national committees, and addressed an ode to Napoleon the liberator, expecting from the military successes of the French general, not merely the overthrow of the effete Venetian oligarchy, but the establishment of a free republican government. The treaty of Campo Formio (17th Oct., 1797), by which Napoleon handed Venice over to the Austrians, gave a rude shock to Foscolo, but did not quite destroy his hopes. The state of mind produced by that shock is reflected in the letters of Jacopo Ortis, a species of political Werther,—for the hero of Foscolo embodies the mental sufferings and suicide of an undeceived Italian patriot just as the hero of Goethe places before us the too delicate sensitiveness embittering and at last cutting short the life of a private German scholar. The story of Foscolo, like that of Goethe, had a groundwork of melancholy fact. Jacopo Ortis had been a real personage; he was a young student of Padua, and committed suicide there under circumstances akin to those described by Foscolo. At this period Foscolo's mind appears to have been only too familiar with the thought of suicide. Cato and the many classical examples of self-destruction scattered through the pages of Plutarch appealed to the imaginations of young Italian patriots as they had done in France to those of the heroes and heroines of the Gironde. In the case of Foscolo as in that of Goethe, the effect produced on the writer's mind by the composition of the work seems to have been beneficial. He had seen the ideal of a great national future rudely shattered; but he did not despair of his country, and sought relief in now turning to gaze on the ideal of a great national poet. At Milan, whither he repaired after the fall of Venice, he was engaged in other literary pursuits besides the composition of *Ortis*. The friendship formed there with the great poet Parini was ever afterwards remembered with pride and gratitude. The friendship formed with another celebrated Milanese poet soon gave place to a feeling of bitter enmity. Still hoping that his country would be freed by Napoleon, he served as a volunteer in the French army, took part in the battle of the Trebbia and the siege of Genoa, was wounded and made prisoner. When released he returned to Milan, and there gave the last touches to his *Ortis*, published a translation of and commentary upon *Callimachus*, commenced a version of the *Iliad*, and began his translation of Sterne's *Sentimental Journey*. The result of a memorandum prepared for Lyons, where, along with other Italian delegates, he was to have laid before Napoleon the state of Italy, only proved that the views cherished by him for his country were too bold to be even submitted to the dictator of France. The year 1807 witnessed the appearance of his *Carme sui Sepolcri*, of which the entire spirit and language may be described as a sublime effort to seek refuge in the past from the misery of the present and the darkness of the future. The mighty dead are summoned from their tombs, as ages before they had been in the masterpieces of Greek oratory, to fight again the battles of their country. The inaugural lecture on the origin and duty of literature, delivered by Foscolo in January, 1809, when appointed to the chair of Italian eloquence at Pavia, was conceived in the same spirit. In this lecture Foscolo urged his young countrymen to study letters, not in obedience to academic traditions, but in their relation to individual and national life and growth. The sensation produced by this lecture had no slight share in provoking the decree of Napoleon by which the chair of national eloquence was abolished in all the Italian universities. Soon afterwards Foscolo's tragedy of *Ajax* was represented but with little success at Milan, and its supposed allusions to Napoleon rendering the author an object of suspicion, he was forced to remove from Milan to Tuscany. The chief fruits of his stay in Florence are the tragedy of *Ricciarda*, the *Ode to the Graces*, left unfinished, and the completion of his version of the *Sentimental Journey*. His version of Sterne is an important feature in his personal history. When serving with the French, he had been at the Boulogne camp, and had traversed much of the ground gone over by Yorick; and in his memoir of Didimo Cherico, to whom the version is ascribed, he throws much curious light on his own character. He returned to Milan in 1813, until the entry of the Austrians; thence he passed into Switzerland, where he wrote a fierce satire in Latin on his political and literary opponents; and finally he sought the shores of England at the close of 1816.

During the eleven years passed by Foscolo in London, until his death there, he enjoyed all the social distinction which the most brilliant circles of the English capital confer on foreigners of political and literary renown, and experienced all the misery which follows on a disregard of the first conditions of domestic economy. His contributions to the *Edinburgh* and *Quarterly Reviews*, his dissertations in Italian on the text of Dante and Boccaccio, and still more his English essays on Petrarch, of which the value was enhanced by Lady Dacre's admirable translations of some of Petrarch's finest sonnets, heightened his previous fame as a man of letters. But his want of care and forethought in pecuniary matters involved him in much embarrassment, and at last consigned him to a prison; and when released, he felt bitterly the change in his social position, and the coldness now shown to him by many whom he had been accustomed to regard as friends. His general bearing in society—if we may accept on this point the testimony of so keen an observer and so tolerant a man as Sir Walter Scott—had unhappily not been such as to gain and retain lasting friendships. He died at Turnham Green on the 10th of October, 1827. Forty-four years after his death, in 1871, his remains were brought to Florence, and with all the pride, pomp, and circumstance of a great national mourning, found their final resting place beside the monuments of Macchiavelli and Alfieri, of Michelangelo and Galileo, in Italy's Westminster Abbey, the church of Santa Croce. To that solemn national tribute Foscolo was fully entitled. For the originality of his thoughts and the splendor of his diction his country honors him as a great classic author. He had assigned to the literature of his nation higher aims than any which it previously recognized. With all his defects of character, and through all his vicissitudes of fortune, he was an ill-judging but always a sincere and courageous patriot. He was, if ever Italian deserved those titles, the precursor and prophet of the unity and independence which his country now enjoys.

Ample materials for the study of Foscolo's character and career may be found in the complete series of his works published in Florence by Le Monnier. The series consists of *Prose letterarie*, in 4 vols., 1850; *Epistolario*, in 3 vols., 1854; *Prose politiche*, 1 vol., 1850; *Poesie*, 1 vol., 1856; *Lettere di Ortis*, 1 vol., 1858; *Saggi di critici storico-letterario*, 1st vol. 1859, 2d vol. 1862. To this series must be added the very interesting work published at Leghorn in 1876, *Lettere inedite del Foscolo, del Giordani, e della Signora di Stael, a Vincenzo Monti*. The work published at Florence in the summer of 1878, *Vita di Ugo Foscolo, di Pellegrino Artusi*, throws much doubt on the genuineness of the text in Foscolo's writings as given in the complete Florence edition, whilst it furnishes some curious and original illustrations of Foscolo's familiarity with the English language. (J. M. S.)

FOSS, **Edward** (1787–1870), a solicitor by profession, was the author of a considerable number of works on legal antiquities, the most important of which are his *Judges of England*, in 9 vols., and his *Biographia Juridica, a Biographical Dictionary of English Judges*. The accuracy and extensive research of the author have made these—especially the larger work—of great historical authority.

FOSSANO, a city of Italy, in the province of Cuneo, on the Stura, about 40 miles from Turin. It is a well-built prosperous place, with a cathedral, an academy of science and letters, a public library, a philharmonic academy, and a veterinary college. Silk and leather are manufactured, and a trade is maintained in grain and cattle. In the 11th century Fossano was a little borough, but in the 13th it was peopled by a body of refugees and raised to considerable importance. The Astigiani family surrounded it with walls shortly afterwards; and in 1314 Filippo d'Acaia laid the foundation of the great four-towered castle, which still forms one of its most striking features. The population in 1871 was 7272 for the town, and 16,544 in the commune.

FOSSANO, **Ambrogio Stefani da**, better known as Ambrogio Borgognone, or simply Il Borgognone, was the foremost painter of the Milanese school, so far as it is possible to speak of a Milanese school independently of Leonardo da Vinci. It is well known how, when Leonardo left Florence to settle at Milan, the influence of his powerful genius presently transformed and dominated the art of those parts of Lombardy. Borgognone was approximately contemporary with Leonardo, but represented, at least during a great part of his career, the tendencies of Lombard art anterior to the arrival of that master—the tendencies which he had adopted and perfected from the hands of his predecessors Foppa and Zenale. We are not precisely informed of the dates either of the death or the birth of Borgognone. His fame is principally associated with that of one great building, the Certosa, or church and convent of the Carthusians at Pavia, for which he worked much and in many different ways. It is certain, indeed, that there is no truth in the tradition which represents him as having designed, in 1473, the celebrated façade of the Certosa itself. His residence there appears to have been of eight years' duration, from 1486, when he furnished the designs of the figures of the Virgin, saints, and apostles for the choir-stalls, executed in *tarsia* or inlaid wood work by Bartolommeo Pola, till 1494, when he returned to Milan. Only one known picture, an altar-piece at the church San Eustorgio, can with probability be assigned to a period of his career earlier than 1486. For two years after his return to Milan he worked at the church of San Satiro in that city. From 1497 he was engaged for some time in decorating with paintings the church of the Incoronata in the neighboring town at Lodi. Our notices of him thenceforth are few and far between. In 1508 he painted for a church in Bergamo; in 1512 his signature appears in a public document of Milan; in 1524—and this is our last authentic record—he painted a series of frescoes illustrating the life of St. Sisinius in the portico of San Simpliciano at Milan. Without having produced any works of signal power or beauty, Borgognone is a painter of marked individuality. He holds an interesting place in the most interesting period of Italian art. The National Gallery of London has two fair examples of his work—the separate fragments of a silk banner painted for the Certosa, and containing the heads of two kneeling groups severally of men and women, and a large altar-piece of the marriage of St. Catherine, painted for the chapel of Rebecchino near Pavia. But to judge of his real powers and peculiar ideals—his system of faint and clear coloring, whether in fresco, tempera, or oil—his somewhat slender and pallid types, not without something that reminds us of northern art in their Teutonic sentimentality as well as their Teutonic fidelity of portraiture—the conflict of his instinctive love of placidity and calm with a somewhat forced and borrowed energy in figures where energy is demanded—his conservatism in the matter of storied and minutely diversified backgrounds—to judge of these qualities of the master as they are, it is necessary to study first the great series of his frescoes and altar-pieces at the Certosa, and next those remains of later frescoes and altar-pieces at Milan and Lodi, in which we find the influence of Leonardo and of the new time mingling with, but not expelling, his first predilections.

FOSSOMBRONE, a town of Italy, in the province of Pesaro and Urbino, about 7 miles from Urbino, on the left bank of the Metauro, which is there crossed by a fine bridge of a single arch. It is commanded by an old castle on the heights, and it possesses a cathedral with ancient inscriptions and pictures, a Capuchin church, a seminary, and the vestiges of a Roman theatre. There are several silk factories in the town, and the silk produced in the district ranks as the finest in all Italy. The population of the town proper in 1871 was 3821, and of the commune 9056.

Of the origin of Fossombrone nothing is definitely known. It appears by the name of Forum Sempronii as a flourishing municipal town under the Roman empire. Ruined by the Goths and Lombards, it was soon afterwards restored on a slightly different site. The Malatesta and Galeazzo families had for a long time possession of the lordship, but they sold it in 1440 to the duke of Urbino.

FOSSOMBRONI, Vittorio (1754–1844), a Tuscan statesman and mathematician, was born at Arezzo in 1754. He was educated at the university of Pisa, where he devoted himself particularly to mathematical science. He obtained an official appointment in Tuscany in 1782, and twelve years later was entrusted by the grand-duke with the direction of the works for the drainage of the Val di Chiana, a task for which he had already shown his fitness by the publication of a treatise on the subject. In 1796 he was made minister for foreign affairs; and on the erection of the grand-duchy into the ephemeral kingdom of Etruria, he became a member of the commission of finance. After the annexation of Tuscany to the French empire, he was created by Napoleon I. chevalier of the Legion of Honor. He was also named head of the commission established for carrying out the drainage of the Pontine marshes. He became first minister of the restored grand-duchy (1814), and his administration, which was only terminated by his death, greatly contributed to promote the well-being of the country. Fossombroni was author of many treatises on mathematical and mechanical science, most of them relating to hydraulics. At the age of seventy-eight he married, and twelve years afterwards died, in 1844, at the age of ninety.

FOSTER, John (1770–1843), an English author and dissenting minister, generally known as the "Essayist," was born in a small farmhouse near Halifax, Yorkshire, September 17, 1770. Partly from constitutional causes, but partly also from the want of proper companions, as well as from the grave and severe habits of his parents, the outward and physical life of boyhood had for him scarcely an existence, and his earlier years were enshrouded in a somewhat gloomy and sombre atmosphere, which was never afterwards wholly dissipated. His youthful energy, finding no proper outlet, developed within him a tendency to morbid intensity of thought and feeling; and, according to his own testimony, before he was twelve years old he was possessed of a "painful sense of an awkward but entire individuality;" what observations he made on men and things were characterized by a precocious shrewdness and gravity, but he lived in an interior world of emotions and sentiments which he recoiled from communicating to any human being; his imagination often exercised on him a tyrannous sway, endowing past or fictitious events with a stronger and more importunate reality than the actual circumstances which surrounded him, and sometimes arousing almost insupportable emotions of pain or terror. A partial counteractive to the predominance of this inward life was supplied by his love of natural scenery, but even here his interest was rather in the grand and sublime than in the beautiful, and nature awakened his strong enthusiasm more frequently than it inspired him with quiet and genial enjoyment. The most wholesome influence exercised on his earlier years was perhaps that obtained from the perusal of books of travel—a species of literature for which he had always a decided preference. It supplied him with actual scenes and adventures on which to exercise his imagination, and helped to deliver him from a too constant contemplation of abstractions and a too minute analysis of his own moods and sentiments. His moral feelings in youth were not only sensitive but deeply rooted and constant and steadfast in their influence, being manifested in entire dutifulness to his parents, strong but "not malicious" antipathies, habitual abhorrence of cruelty, intense love of the heroic, and a tone of mind whose seriousness was excessive.

The small income accruing to Foster's parents from their farm they supplemented by weaving, and at an early age he began to assist them by spinning wool by the hand wheel, and from his fourteenth year by weaving double stuffs. Even "when a child," however, he had the "feelings of a foreigner in the place;" and though he performed his monotonous task with conscientious diligence, he succeeded so indifferently in fixing his wandering thoughts upon it that his work never without difficulty passed the ordeal of inspection. There is little information as to the manner in which he obtained his primary education, but at an early period he had acquired a great taste for reading, to gratify which he sometimes shut himself up alone in a barn, afterwards working at his loom "like a horse," to make up for lost time. He had also at this period "a passion for making pictures with a pen." Shortly after completing his seventeenth year he became a member of the Baptist church at Hebden Bridge, with which his parents were connected; and with the view of preparing himself for the ministerial office, he began about the same time to attend a seminary at Brearley Hall conducted by his pastor Dr. Fawcett. The mental processes of Foster followed a course which was entirely their own, and the manner of their operation was often awkward and unwieldy. He had difficulty in bending his attention to the continuous contemplation of a subject as it had been viewed by others, and smaller niceties and details only made an impression on his mind after a repeated perusal. He therefore mastered his tasks very slowly and with great labor, and his application was so intense and protracted as to awaken the serious anxiety of his friends. To excel in literary composition was the purpose which occupied his most eager attention, and with a view to obtain facility and variety of diction, it was his custom to select paragraphs from different writers and to alter the structure and expression of each sentence in as many different ways as his ingenuity could invent, a method which, if it helped him to acquire the particular kind of flexibility which his style afterwards manifested, was perhaps also in part the means of betraying him into his occasional use of lumbering expressions, and of a harsh, involved, or clumsy order of arrangement.

After remaining three years at Brearley Hall he was admitted to the Baptist College, Bristol, and on finishing his course of study at this institution, he obtained an engagement at Newcastle-on-Tyne, where he preached to an audience of less than a hundred persons, in a small and dingy room situated near the river at the top of a flight of steps called Tuthill stairs. At Newcastle he remained only three months. In the beginning of 1793 he proceeded to Dublin, where after failing as a preacher he attempted to revive a classical and mathematical school, but with so little success that he did not prosecute the experiment for more than eight or nine months. From 1797 to 1799 he was minister of a Baptist church at Chichester, but though he applied himself with more earnestness and perseverance than formerly to the discharge of his ministerial duties, his efforts produced little apparent impression, and the gradual diminution of his hearers necessitated his resignation. After employing himself for a few months at Battersea in the instruction of twenty African youths brought to England by Zachary Macaulay, with the view of having them trained to aid as missionaries to their fellow-countrymen, he in 1800 accepted the charge of a small congregation at Downend, Bristol, where he continued about four years. In 1804, chiefly through the recommendation of Robert Hall, he became pastor of a congregation at Frome, but a swelling in the thyroid gland compelled him in 1806 to resign his charge. In the same year he published the volume of *Essays* on which his literary fame most largely if not mainly rests. They were written in the form of letters addressed to the lady whom he afterwards married, and consist of four papers,—"On a Man writing Memoirs of himself;" "On Decision of Character;" "On the Application of the Epithet Romantic;" and "On some Causes by which Evangelical Religion has been rendered unacceptable to Men of Cultivated Taste." The success of this work was immediate, and was so considerable, that on resigning his charge he determined to adopt literature as his profession. The *Eclectic Review* was the only periodical with which he established a connection; but his contributions to that journal, which were begun in 1807, number no fewer than 185 articles. On his marriage in May, 1808, he removed to Bourton-on-the-Water, a small village in Gloucestershire, where he remained till 1817, when he returned to Downend and resumed his duties to his old congregation. Here he published in 1820 his *Essay on Popular Ignorance*, which was the enlargement of a sermon originally preached on behalf of the British and Foreign School Society. He describes this essay with a certain degree of happiness and accuracy as a "broad, true, and strongly delineated picture of the intellectual and moral state of the mass of our people;" only it must be added that the contemplation of the gloomy features of his subject has so reacted on his vision that an artificially darkened atmosphere seems to overspread his whole canvas, and his picture somewhat resembles that of a landscape painted during an eclipse. In 1821 he removed to Stapleton near Bristol, and in 1822 he began a series of fortnightly lectures at Broadmead Chapel, Bristol, which were afterwards published in 2 vols. On the settlement of Robert Hall at Bristol this service was discontinued, as in such circumstances it appeared to Foster to be "altogether superfluous, and even bordering on impertinent." The health of Foster during the later years of his life was somewhat infirm, the result chiefly of the toil and effort of literary composition; and the death of his only son, his wife, and the greater number of his most intimate friends, combined with his bodily ailments to lend additional sombreness to his manner of regarding the events and arrangements of the present world—the "visage of death" being almost his "one remaining luminary." He died at Stapleton, 15th October, 1843.

The cast of Foster's mind was meditative and reflective rather than logical or metaphysical, and though holding moderately Calvinistic views, his language even in preaching very seldom took the mould of theological forms. His "apprehension of the divine mercy, and of the terms of hope and safety for poor mortals, was," he says, "widely remote from the austerity of the systematic divines." He rejected the doctrine of eternal punishment, because the idea of such protracted and hopeless misery following such a "brief trial and sojourn on earth" seemed inconsistent with the divine goodness, and he was thus compelled to believe that the language of Scripture which seemed to support this doctrine was susceptible of another and milder interpretation. Though always retaining his connection with the Baptist denomination, the evils resulting from organized religious communities seemed to him so great that he came to be "strongly of opinion that churches are useless and mischievous institutions, and the sooner they are dissolved the better." The only Christian observances which he regarded as of any importance were public worship and the Lord's Supper, and it so happened that he never administered the ordinance of baptism.

Though he was mild and charitable in his interpretation of the conduct of individuals, his moral constitution was narrow and stern rather than sympathetic, and his creed left little room for laughter, and on the question of amusements was strongly puritanical. The dark and sombre scenes which his imagination so vividly pictured forth riveted his contemplation by a fascination from which he vainly struggled to be free. With such mournful views of life the "weight of this unintelligible world" pressed rather heavily upon him, and his cast of thought is largely colored by a constant reference to the "endless future." He was a firm believer in supernatural appearances, and cherished a longing hope that a ray of light from the other world might sometimes in this way be vouchsafed to mortals.

Apart from the singularity of his modes of thought, and the unusual forms of his spoken as well as his written style, Foster was constitutionally unfitted to excel as an orator, and Robert Hall testifies that "though his words might be fire within, the moment they left his lips they froze and fell down at his feet." As a writer his most characteristic quality is his searching discernment of every kind of moral falsity and weakness, the dark and subtle windings of which he tracks with unerring and dogged sagacity, and exposes either with easy irony, or with a keen and scathing satire, whose indignation, however, is slightly qualified by a faint suggestion of sorrowful contempt. He often strangely interweaves the hackneyed and commonplace with the novel and unexpected. The substance of his thought is old and worn, but after passing through the crucible of his mind it acquires a brilliant lustre, and he places it in such new and striking lights that his exhibition of it resembles the revelation of something hitherto unknown. He is, however, so intent on adequately representing the minutest aspects of his subject that he does not sufficiently distinguish between the important and the unimportant; and he often employs a beautiful, sometimes a sublime, figure to illustrate either an almost self-evident proposition, or a thought otherwise much too lowly for such a splendid dress; while, on the other hand, an elevated thought or sentiment is sometimes associated with imagery as much out of harmony with its surroundings and position as would be the rags of a beggar with the splendor and magnificence of a court. His originality consists chiefly in placing old and time-honored beliefs in new and unexpected relations, and imparting a vividness to truths which are so generally recognized that their importance is almost forgotten. He has therefore given no new impulse to thought, and he has scarcely entered upon the threshold of the speculation and ideas of the 19th century. Though his intellectual was much wider than his moral sympathy, his literary criticisms—apart from the fact that they are totally unfettered by artificial rules and maxims, and record in ingenuous language the actual impression produced upon his mind by the work he examines—are chiefly of value for their keen detection of what is hollow and false in sentiment, and their sarcastic exposure of affectation and pretence. He wrote with intense mental strain and effort, and sometimes spent days in the elaboration of a single paragraph. His style has the merit of entire individuality; as he himself says, his "language is simply and absolutely formed for the thought—is adapted and flexible to it—is taken out of the whole vocabulary of our tongue just on purpose for the thoughts, and moulded to their very shape, with an almost perfect independence and avoidance of all the set artificial forms of expression." With this merit, however, it has the defects formerly adverted to; and while scarcely ever weak or ambiguous, but even in the midst of its frequent involutions surprising by terse and pointed or vivid and graphic interpolations, and preserving throughout its winding structure a compact, nervous, and sinewy strength which occasionally assumes the form of a rhythmical and measured eloquence, it is yet on the whole deficient in directness, freedom, ease, and grace.

Besides the works already alluded to, Foster is the author of a *Discourse on Missions*, 1818; "Introductory Essay" to Doddridge's *Rise and Progress of Religion*, 1825; "Observations on Mr. Hall's Character as a Preacher," prefixed to the collected edition of Hall's *Works*, 1832; an "Introduction" to a pamphlet by Mr. Marshman on the Serampore Missionaries; several political letters to the *Morning Chronicle*, and contributions to the *Eclectic Review*, published posthumously in 2 vols., 1844. His *Life and Correspondence*, edited by J. E. Ryland, originally published in 1846, has passed through several editions.

(T. F. H.)

FOSTER, STEPHEN COLLINS (1826–1864), a prolific American song and ballad writer, was born at Alleghany, Pennsylvania, July 4, 1826. He was the youngest child of a merchant who became mayor of his native city, and a member of the State legislature, and was related by marriage to President Buchanan. As a boy Stephen was delicate, and through life he was of a quiet, retiring disposition—in strong contrast with the spirit of many of his most popular songs. He early showed talent for music, and played upon several instruments; he also acquired a fair knowledge of French and German. When thirteen years old he wrote a song afterwards published in his works —"Sadly to Mine Heart Appealing." At sixteen he wrote the then much admired "Open thy Lattice, Love;" at seventeen he entered his brother's business house, Cincinnati, Ohio, where he remained about three years, composing meanwhile such popular pieces as "Old Uncle Ned," "O Susanna!" etc. For the latter he received 100 dollars, which induced him to adopt song-writing as a vocation. His chief successes were songs written for the negro melodists or "minstrels." Besides those mentioned, the following attained great popularity, viz., "Nellie was a Lady," "Old Kentucky Home," "Old Folks at Home," "Massa's in the Cold Ground," etc. For these and other songs the composer received considerable sums, "Old Folks at Home" bringing him, it is said, 15,000 dollars. For the most of his songs Foster wrote both words and music. His reputation rests chiefly on his negro melodies, many of which have been popular on both sides of the Atlantic, and sung in many tongues. His later songs were of a more refined and somewhat higher order of musical composition, and after his mother's death were characterized by melancholy. Among these are "Old Dog Tray," "Gentle Annie," "Willie, we have missed you," etc. His "Come where my Love lies Dreaming" is considered one of the most pleasing and popular vocal quartets ever written. Composers and poets of celebrity recognized his peculiar talent, and great musicians incorporated many of his melodies into concert fantasias. Although as a musician and composer Foster would, strictly speaking, have little claim to high rank, his song-writing made an epoch in popular music of a class which certainly possessed melody united to beauty of harmony, while to the words employed he gave fitting musical expression. He died at New York, January 13, 1864.

FOTHERGILL, John (1712–1780), F.R.S., an eminent physician, a member of the Society of Friends, was born at Carr End in Yorkshire. He took the degree of M.D. at Edinburgh in 1736. After visiting the Continent, he in 1740 settled in London, and gained there an extensive practice. In the epidemics of influenza in 1775 and 1776 he is said to have had sixty patients daily. In his leisure he made a study of conchology and botany; and after his death, which took place in December, 1780, his collections of shells, prints, and other objects were sold for a considerable sum. Fothergill was a licentiate of the College of Physicians of London, and a fellow of that of Edinburgh, of which he was a great benefactor. He was the patron of Sidney Parkinson, the South Sea voyager. A translation of the Bible (1764 *sq.*) by Anthony Purver, a Quaker, was made and printed at his expense. His pamphlet entitled *Account of the Sore Throat attended with Ulcers* (1748, 2d ed. 1754), prepared with the assistance of information supplied by Dr. Letherland, attracted great attention, and was translated into several languages. His works were edited by Dr. John Elliot (1781), by Gilbert Thomson (1782), and by Dr. Lettsom (1783).

FOUCAULT, Jean Bernard Léon (1819–1868), a distinguished French physicist, was the son of a well-known publisher at Paris, where he was born September 18, 1819. After an education received chiefly at home, he studied medicine, which, however, he speedily abandoned for physical science, the improvement of Daguerre's photographic processes being the object to which he first directed his attention. During three years he was experimental assistant to M. Donné in his course of lectures on microscopic anatomy. With M. Fizeau he carried on a series of investigations on the intensity of the light of the sun, as compared with that of carbon heated in the voltaic arc, and of lime in the flame of the oxyhydrogen blowpipe; on the interference of heat rays, and of light rays differing greatly in lengths of path; and on the chromatic polarization of light. In 1849 he contributed to the *Comptes Rendus* of the Academy of Sciences, t. xxviii., a description of an electro-magnetic regulator for the electric lamp, and, in conjunction with Regnault, a paper on binocular vision. By the use of a revolving mirror similar to that used by Wheatstone for measuring the rapidity of electric currents, but having a concave mirror centred in its axis, he was enabled in 1850 to demonstrate the greater velocity of light in air than in water, and to establish the law deduced from the undulatory theory that the velocity of light in different media is inversely as the refractive indices of the media. In the same year he was created a chevalier of the Legion of Honor. For his demonstration in 1851 of the diurnal motion of the earth by the rotation of the plane of oscillation of a freely suspended, long, and heavy pendulum in an E.S.W. direction, exhibited by him at the Pantheon in Paris, and again in the following year by means of his invention the gyroscope, he in 1855 received the Copley medal of the Royal Society of London. He was also in 1855 made physical assistant in the imperial observatory at Paris. In September of that year he discovered that the force required for the rotation of a copper disc moving in its own plane becomes greater, the disc at the same time growing hotter, when the disc is made to rotate with its rim between the poles of a horse-shoe magnet. Foucault invented in 1857 the polarizer which bears his name, and in the succeeding year a method of giving to the speculum of reflecting telescopes the form of a spheroid or a paraboloid of revolution. His reflector for the great telescope in the Paris observatory was mounted in June, 1859. With Wheatstone's revolving mirror he in 1862 determined the absolute velocity of light to be 298,000 kilometres (about 185,000 miles) a second, or 10,000 kilom. less than that obtained by previous experimenters. He was created in that year a member of the Bureau des Longitudes and an officer of the Legion of Honor, in 1864 a foreign member of the Royal Society of London, and next year a member of the Mechanical Section of the Institute. In 1865 appeared his papers on a modification of Watt's governor, upon which he had for some time been experimenting with a view to making its period of revolution constant, and on a new apparatus for regulating the electric light; and in the following year (*Compt. Rend.* lxiii.) he showed how, by the deposition of a transparently thin film of silver on the outer side of the object glass of a telescope, the sun could be viewed without injuring the eye by excess of light. Foucault died of paralysis, February 11, 1868. From the year 1845 he edited the scientific portion of the *Journal des Débats.* His chief scientific papers are to be found in the *Comptes Rendus*, t. xxv., 1847–lxix., 1869.

See *Revue Cours Scient.* vi., 1869, pp. 484–489; *Proc. Roy. Soc.* xvii., 1869, pp. lxxxiii.–lxxxiv.; Lissayous, *Notice historique sur la vie et les travaux de Léon Foucault*, Paris, 1875.

FOUCHÉ, Joseph (1763–1820), duke of Otranto, minister of police under Napoleon I., was born in a small village near Nantes, 26th May, 1763. He was the son of a ship captain, and at the age of nine years began the study of mathematics at the college of his native place, with the view of entering the merchant marine. That such a calling would have proved congenial to him is not very probable, and at any rate it presented so little attraction to his youthful fancy that he induced his father to consent to the abandonment of this intention, and to permit him to continue his studies at Paris under the superintendence of the principal of the Oratory. He afterwards taught successively in the colleges of Juilly, Arras, and Vendôme; and at the time of the Revolution he was *préfet des études* at Nantes. He now renounced his connection with the ecclesiastical profession, and in 1792 succeeded in being chosen one of the national deputies for Loire-Inférieure. In this capacity he made a violent speech in support of the execution of Louis XVI., without respite and without appeal to the people, taunting those who hesitated to adopt such an extreme measure with "trembling before the shade of a king." In the midst of the political chaos he determined to "ride on the whirlwind and direct the storm:" though he had little or no interest in moral speculation, he became an ardent asserter of atheism; and, though devoid of all political predilections, and actuated in his political purposes simply by a cool calculation of advantages that was seldom if ever surprised or ruffled even by the most critical contingencies, he soon manifested a zeal for republicanism which exceeded that of the wildest enthusiasts of that exceptional time. Having at the end of 1793 been commissioned to put in operation the law *des suspects* in the department of Nièvre, then one of the centres of the royalist sympathizers, he not only succeeded in completely crushing all insurrectionary symptoms, but initiated the movement for the spoliation of the churches, by which the treasury was supplied with money for the campaign of 1794; and he also further inaugurated the age of reason by suppressing the priests and causing to be inscribed on the doors of the cemeteries a sentence afterwards generally adopted for this purpose—*La mort est un sommeil éternel.* In November of the same year he was appointed, along with Collot d'Herbois, to execute the decree of the convention against the royalist city of Lyons; and here he vied with his colleague in a mania for destruction and bloodshed, inditing bombastic regrets that the mine and the guillotine did their work too slowly to accord with the impatience of the republic or to express the omnipotence of the people. This devoted enthusiasm for freedom led to his being elected president of the Jacobin Club, 4th June, 1794, soon after his return to Paris. He now so far allowed his audacity to overcome his discretion as to make some derisive allusions to the part played in the fête de l'Être Suprême by Robespierre, who on that account denounced him as an impostor and peculator, and procured his expulsion from the society. Fouché had erred, however, only by a too quick anticipation of public opinion, for the execution of Robespierre followed on the 25th July. The star of Fouché was thus for a short time again in the ascendant; but having awakened distrust by some new intrigues, he was denounced as a terrorist, expelled the convention 9th August, 1795, and placed under arrest. He obtained his freedom by the amnesty of the 26th October following; and having obtained the confidence of the socialist Babeuf, and revealed his conspiracy to Barras, then president of the directory, he was rewarded by an interest in the contracts of the army, and by being appointed in 1798 ambassador to the Cisalpine republic. Soon afterwards his intrigues against the directory of Milan led to his recall, but when the party of Barras again came into power he was appointed to the Hague. There he remained only a few months, returning to Paris to enter upon his famous career as minister of police. In this capacity he for some years exercised an influence on the internal affairs of France perhaps greater than that of any one else; and it was chiefly owing to his well-chosen measures of repression, his ready and dexterous use of expedients, his almost omniscient faculty of detection, and his just appreciation of political contingencies, that at this critical period of France's history the reign of anarchy was averted. Recognizing the necessity of a new political departure, he suppressed the Jacobin clubs and newspapers, and was concerned in instigating the beginning of a reaction towards monarchical principles. Though he failed to effect an understanding between Barras and Napoleon, he resolved rather to desert his patron than to share his overthrow, and exerted all his powers of management and finesse to bring the *coup d'état* of the 18th Brumaire to a successful termination. Besides taking an important though carefully guarded share in the preliminary negotiations, he suspended in the name of the directory the twelve municipalities of Paris, tranquillized the citizens by posting on the walls reassuring intimations, and took the precaution of shutting the gates of Paris to prevent the fugitive deputies from re-entering the city.

Under the consulate, Fouché, notwithstanding the opposition of Sieyès, was continued minister of police, partly because he was to be dreaded as an opponent, and partly because no one else could bear comparison with him in fitness for the office. Its duties he discharged, not only with unequalled tact and discretion, but with a justice and mildness rendered possible only by his perfect confidence in his superior cunning. At the same time there was necessarily attached to it a very great irresponsible power, and far from neglecting to make undue use of this he took care to lend an additional appearance of necessity and value to his services by a continual supply of political fomentations. If his audacity and assumption aroused the jealousy of Napoleon, his cool impenetrability no less disconcerted him, and matters were not improved by the ludicrous blunders of the secret police which Napoleon had the folly to employ, in order both to test his minister's fidelity and render him less indispensable. Actuated therefore most probably by a regard to his own position, Fouché endeavored to prevent a too rapid abandonment of the lines of republicanism, and deprecated as imprudent the means that were being used towards the establishment of a monarchical government. Such advices doubtless increased Napoleon's irritation and distrust, and on becoming consul for life in 1802 he determined to rid himself of the galling fetters of his minister's ascendency. He did this, however, with great caution and respect; and while he suppressed the office as no longer necessary, he conferred on Fouché the dignity of a senator, and presented him with half the police reserve funds. The association of the functions of the old office with those of the ministry of justice did not prove a happy arrangement; and Fouché, by maintaining for his own purposes the same system of espionage as formerly, was able, by revealing the Georges conspiracy, to reassert his influence in the affairs of state. Divining Napoleon's secret wishes and intentions, he now took every opportunity to press upon him the advisability of immediately assuming the monarchical crown, and applied himself to the furtherance of this object with an ostentatious zeal that was doubtless meant to suggest that he was almost the sole agent in determining events towards that end. And indeed he might, after Napoleon, justly claim the chief merit of that great political change, for at any rate the smoothness with which it was accomplished was greatly due to Fouché's skilful management.

After Napoleon's coronation Fouché was therefore reinstalled in his old office, 4th July, 1804, uniting with its functions those of the ministry of the interior. In this position he took a very prominent part in the rule of France under Napoleon, and to some extent rivalled his master in influence; for if the empire gained glory by Napoleon's achievements, it owed its internal harmony to Fouché, who had for a time the entire direction of its administration. On the revival of the titles of nobility he was created duke of Otranto, and it appeared as if his tenure of office were indissolubly connected with the empire's stability. The bond between him and the emperor was, however, solely one of interest, and the very antipodes of one of affection and mutual esteem. His imperturbable self-control, his connection with the old republicans, the obscurity and mystery in which he shrouded his intentions, and his power of secret strategy gained him almost a kind of mastery over the arbitrary spirit of Napoleon, but it was a mastery borne both with impatience and with resentment. Apart from this, his cold and vulgar ambition and his cynical contempt for all unsubstantial glory irritated the sensitive egoism of Napoleon, whose magnificent projects he often pierced with shafts of truth that were too painfully effective, and whom he somewhat imprudently tormented with warnings as to the necessity of limiting his designs of conquest. When matters were in this critical condition, they were brought to a crisis by a proclamation of Fouché calling on France—then threatened by the English invasion—to prove that Napoleon's presence was not necessary to scatter his enemies. The proclamation was effectual; but on Napoleon's return to Paris Fouché was deprived of the ministry of the interior. Shortly afterwards he sent an agent to England to carry on negotiations with the English Government, in ignorance that Napoleon had sent another for the same purpose; and the English minister, suspecting a trick, declined all further negotiations. This mischance completed Fouché's disgrace; he ceased to be minister of police, 3d June, 1810; and to secure his absence from France, he was appointed governor of Rome. While delaying his departure he was requested to deliver up the autograph letters of Napoleon and other Government documents in his possession; and his answer that they were all destroyed was deemed so little satisfactory that he found it expedient to go into voluntary exile. On delivering up the papers the destruction of which he had asserted, he was afterwards permitted to return to his estate at Pont-Carré; but in 1813 Napoleon judged it prudent to appoint him governor of Illyria, after which he was sent to Rome to watch the movements of Murat. Being recalled to France some time before the entrance of the allies into Paris, he in anticipation of events came to an understanding with Talleyrand, and becoming one of the principal members of the provisional Government, proposed that a deputation should be sent to the Comte d'Artois, brother of Louis XVIII. He afterwards wrote letters to the king recommending the adoption of certain measures fitted to reconcile the opponents of the Bourbon dynasty, and on the 25th April addressed a letter to Napoleon at Elba, advising him, instead of making an effort to remount the throne of France, to seek a sphere for his ambition in America, "where his genius would be admired without being feared." On the news of Napoleon's escape from Elba the Government of Louis offered Fouché the portfolio of police, but he declined it on the ground that the Government could no longer hold its position. Next day he was ordered to be arrested, but deluding by a clever stratagem the officers sent for that purpose, he escaped to the hôtel of Hortense Beauharnais, and received on the following day his old office from the hands of Napoleon. He now determined merely to prepare for Napoleon's downfall, which he saw to be imminent; and besides securing the confidence of both patriots and royalists, he opened a communication with the allies. After the battle of Waterloo it was therefore to him that all eyes turned for guidance; and, becoming the head of the provisional Government, he succeeded in producing the impression that his skilful diplomacy had saved Paris from extreme humiliation. Having played such an important part in this political crisis his name could not be omitted from the list of the new Government, and he received his old office from the king, of whose brother's death he had been one of the principal instigators. His dexterity, however, had now set itself a task for which it was incompetent; and gradually finding his position untenable, he resigned office 19th September, 1815. As a kind of solatium he was appointed ambassador to Dresden; but on the passing of the law of banishment against those who had voted for the death of Louis XVI., he retired to Prague. He became a naturalized Austrian subject in 1818, and died at Trieste, 25th December, 1820, in possession of enormous wealth.

Fouché, notwithstanding his equivocal expression of countenance and his known untrustworthiness, had a peculiar faculty of captivating the eminent politicians with whom he came into contact. This was due at once to his instinctive divination of their weak point, and to his wonderful knowledge of the varying conditions of the political barometer. Though somewhat boastful, his conversation was remarkably agreeable and interesting, and was frequently lighted up by terse and sarcastic witticisms which would have done credit to Talleyrand. His temperament was too cold to enable him to achieve success as an orator, but his writings, though sometimes bombastic, must be allowed the merit of cleverness, and are often characterized by a graphic felicity. His unparalleled political career is to be accounted for not perhaps so much by his peculiar intellectual abilities as by the apparent fact that he was, as M. Thiers has expressed it, completely "indifferent to good and evil"—that he was influenced neither by the impulses of passion nor by the dictates of conscience. His private life was virtuous compared with that of many of his contemporaries, and his political life—apart from his connection with the death of Louis XVI., and the atrocities of Nantes and Lyons—was not only unstained by heinous crime, but to an unenlightened spectator seemed wholly devoted to the public interest. Inhabiting a region beyond the influence of party bias, he appeared when a political crisis was at hand almost in the character of the guardian angel of France, cherishing no remembrance of past ingratitude, but benevolently proffering for her acceptance the only aid that could save her from disaster. He was, if not the leading actor, at least the principal wire-puller and prompter in many of the great events of his time; but his only important legacy to posterity is the grand spy-system which he brought almost to perfection, and which has since exercised such a baneful influence on European politics. Next to his love of intrigue, his main motive in all his purposes was something resembling avarice; but in all probability he did not love even money, and sought to lay hold of it chiefly as the one stable rock amid the billows and quicksands of political life. Though his purposes were not held in check by any moral principle, yet so strong was his self-control, and so calm his estimate of possibilities, that he never committed himself irrevocably to a conspiracy that was not successful. The atrocities, however, which inaugurated his political career, and at the close of it his acceptance of office under Louis XVIII., were, though widely separated in time, so incompatible with each other that he at last completely lost the confidence of all parties in the state, and his past career was placed in a light so strongly sinister as to render its character unmistakable. Many politicians of his own time had been guilty of equally heinous crimes; but few of any age have so consistently and uninterruptedly sacrificed every political and moral consideration, including that of self-respect, to a temporary success.

Fouché is the author of *Réflexions sur le jugement de Louis Capet*, 1793; *Réflexions sur l'éducation publique*, 1793; *Rapport et projet de loi relatifs aux colléges*, 1793; *Rapport sur la situation de Commune-Affranche*, 1794; *Lettre aux préfets, concernant les prêtres, etc.*, 1801; two *Rapports aux Roi* and *Notes aux ministres étrangers*, 1815, where he ably discusses the condition of France at the time; and *Lettre au duc de Wellington*, 1817. He is said to have been the author of the *Précis de la vie publique du duc d'Otrante*, published at London and Leipsic in 1816. The *Mémoires de Fouché*, Paris, 1824, were declared by his family to be a forgery, but although their naïveté is often too pronounced to be compatible with their authenticity, they are evidently founded on original sources of information. See also *Vie de Fouché*, 1821; Bourrienne, *Life of Napoleon;* Desmarest, *Témoignages historiques, ou quinze Ans de haute police sous Napoléon*, 1833; Martel, *Étude sur Fouché et sur le communisme dans le pratique en 1793*, 1873, which contains a number of documents never before published; and an interesting account of an interview with Fouché by Earl Stanhope, in Lord Brougham's collected works, vol. v. (T. F. H.)

FOUCHER, Simon (1644–1696), a sceptical writer during the latter part of the 17th century, was born at Dijon on the 1st March, 1644. Extremely little is known of his life. He was the son of a merchant at Dijon, and appears to have taken orders at a very early age. For some years he held the position of honorary canon at Dijon, but this he resigned in order to take up residence in Paris. He graduated at the Sorbonne, and spent the remainder of his life in literary work in Paris. Foucher's name is now almost completely forgotten, but in his day he enjoyed considerable repute as a keen opponent of Malebranche. His point of view in philosophy may be called the sceptical, but the scepticism extends to only one doctrine, external perception. On this point he revived the old arguments of the Academy, and advanced them with much ingenuity against Malebranche's doctrine. Otherwise his scepticism is subordinate to orthodox belief, the fundamental dogmas of the church seeming to him intuitively evident. His writings against Malebranche were collected under the title *Dissertations sur la Recherche de la Vérité*, 1693. See Rabbe, *L'Abbé Simon Foucher*, Dijon, 1867.

FOUGÈRES, a town of France, at the head of an arrondissement in the department of Ille-et-Vilaine, situated for the most part on an eminence near the left bank of the Nançon, a tributary of the Couesnon, by which the lower town is not unfrequently laid under water. It was formerly one of the strongest places on the frontier towards Normandy, and it still preserves some portions of its 15th-century walls. The castle is now a picturesque ruin, with abundant evidence in its noble towers and outworks at once of its strength and its magnificence. The finest of all the towers was erected in 1242 by Hugues of Lusignan, and named after Melusine the mythical foundress of the family. The churches of St. Léonard and St. Sulpice both date, at least in part, from the 15th century; and the town-hall has a gate of the 16th and a belfry tower of the 15th. Among the other public buildings are a hospital founded in 1688, a civil and military prison, an institution for deaf mutes, an orphanage, and a normal school. The trade and manufactures of the town are considerable—the former consisting mainly of agricultural and dairy produce, and the latter of shoes and boots, sail-cloth and other hempen fabrics, flannel, hats, and leather. Fougères frequently figures in history from the 11th to the 15th century. It was taken by the English in 1202, and again in 1448; and the name of Surienne, the captor on the second occasion, is still borne by one of the towers of the castle. Population in 1851, 8771; in 1876, 10,396.

FOULD, Achille (1800–1867), French financier and politician, was born at Paris, November 17, 1800. The son of a rich Jewish banker, he was associated with and afterwards succeeded his father in the management of the business. As early as 1842 he entered political life, having been elected in that year as a deputy for the department of the Hautes Pyrénées. From that time to his death he actively busied himself with the affairs of his country. He readily acquiesced in the revolution of February, 1848, and is said to have exercised a decided influence in financial matters on the provisional Government then formed. He shortly afterwards published two pamphlets against the use of paper money, entitled, *Pas d' Assignats!* and *Opinion de M. A. Fould sur les Assignats.* During the presidency of Louis Napoleon he was four times minister of finance, and took a leading part in the economical reforms then made in France. His strong conservative tendencies led him to oppose the doctrine of free trade, and disposed him to hail the "Coup d'État" and the new empire. On the 25th of January, 1852, in consequence of the decree confiscating the property of the Orleans family, he resigned the office of minister of finance, but was on the same day appointed senator, and soon after rejoined the Government as minister of state and of the imperial household. In this capacity he directed the Paris exhibition of 1855. The events of November, 1860, led once more to his resignation, but he was recalled to the ministry of finance in November of the following year, and retained office until the publication of the imperial letter of the 19th of January, 1867, when M. Émile Olivier became the chief adviser of the emperor. During his last tenure of office he had reduced the floating debt, which the Mexican war had considerably increased, by the negotiation of a loan of 300 millions of francs (1863). Fould, besides uncommon financial abilities, had a taste for the fine arts, which he developed and refined during his youth by visiting Italy and the eastern coasts of the Mediterranean. In 1857 he was made an honorary member of the Academy of the Fine Arts. He died at Tarbes on the 5th October, 1867.

FOULIS, Andrew and Robert, two learned Scotch printers and publishers, whose enterprise and devotion to the interests of the higher education deserve to be gratefully remembered. Robert, the elder of the two, was born in 1707, and his brother in 1712. Their father was a maltman in Glasgow, and they consequently had very ordinary opportunities for intellectual culture in their early years. Robert was apprenticed to a barber; but his ability attracted the attention of Dr. Francis Hutchison, who strongly recommended him to establish a printing press. After spending 1738 and 1739 in England and France in company with his brother Andrew, who had been intended for the church and had received a better education, he started business about 1740–1, and in 1743 was appointed printer to the university. In this same year he brought out Demetrius Phalereus, the first Greek book ever printed in Glasgow; and this was soon followed by the famous 12mo edition of Horace, which was long but erroneously believed to be immaculate: though the successive sheets were suspended in the university and a reward offered for the discovery of any inaccuracy, six errors at least, according to Dibdin, escaped detection. Soon afterwards the brothers entered into partnership, and they continued for about 30 years to issue carefully corrected and elegantly printed editions of classical works in Latin, Greek, English, French, and Italian. Upwards of 500 separate publications proceeded from their press—among the more noticeable being the small editions of Cicero, Tacitus, Cornelius Nepos, Virgil, Tibullus and Propertius, Lucretius, and Juvenal; a beautiful edition of the Greek Testament in small 4to; Homer, 4 vols. fol., 1756–1758; Herodotus, Greek and Latin, 9 vols. 12mo, 1761; Xenophon, Greek and Latin, 12 vols. in 12mo, 1762–1767; Gray's Poems; Pope's Works; Milton's Poems. The brothers spared no pains, and Robert went to France to procure manuscripts of the classics, and to engage a skilled engraver and a copper-plate printer. Unfortunately it became their ambition to establish an institution for the encouragement of the fine arts; and though one of their chief patrons, the earl of Northumberland, warned them to "print for posterity and prosper," they spent their money in collecting pictures, pieces of sculpture, and models, in paying for the education and travelling of youthful artists, and in copying the masterpieces of foreign art. Their countrymen were not ripe for such an attempt, and the "Academy" not only proved a failure but involved the projectors in ruin. Andrew died in 1775, and his brother went to London, hoping to realize a large sum by the sale of his pictures. They were sold for much less than he anticipated, and he returned broken-hearted to Scotland, where he died at Edinburgh in June, 1776. The debts of the firm amounted to £6500. Robert was the author of a *Catalogue of Paintings with Critical Remarks*, 3 vols.

See W. J. Duncan, *Notices and Documents illustrative of the Literary History of Glasgow*, printed for the Maitland Club, 1831, which *inter alia* contains a catalogue of the works printed at the Foulis press, and another of the pictures, statues, and busts in plaster of Paris produced at the "Academy" in the university of Glasgow.

FOUNDING, the art of reproducing solid objects in metal or other fusible substances by pouring the melted substance into moulds. It is also known as *casting*, and objects so produced are said to be of cast metal. Works where founding or casting is carried on are termed foundries, and their proprietors founders. The verb to found is not, however, in current use, being almost entirely replaced by cast. The root of the word is the Latin *fundus*.

Three principal operations are involved in founding:—(1) moulding, or the production of a hollow mould to receive the melted metal; (2) melting, or running down the metal; and (3) pouring, or filling the mould with the liquid metal. The preparation of the original object or pattern from which the mould is made is not strictly part of foundry work proper, the founder receiving the pattern prepared in wood from the original drawings from the engineer's patternmaker, except in those cases where no pattern is required, and the model is built up on the foundry floor by the moulder by the use of revolving templates, dividing engines, or other contrivances.

The metals best suited for foundry work are those that possess the property of increasing in volume at the moment of passage from the liquid to the solid state, so that its particles may be pressed into and fill up the finest cavities of the mould in setting. This property is best developed in bismuth, the alloys of copper with tin and zinc (bronze and brass), and cast iron. Lead does not take a sharp impression unless alloyed with tin or antimony, as in type metal. Copper also does not give sound castings.

Patterns for moulding require to be made somewhat larger than the cast required, the difference being determined by the linear dilatation of the metal between the ordinary temperature and that at the moment of solidification. This varies for different metals; for cast iron it is about $\frac{1}{96}$; for hard bronze, $\frac{1}{63}$; soft bronze, $\frac{1}{134}$; brass, $\frac{1}{65}$; zinc, $\frac{1}{62}$; lead, $\frac{1}{92}$; tin, $\frac{1}{147}$; and bismuth, $\frac{1}{265}$. Patterns for iron founders are therefore made larger than the finished size required in the proportion of one-eighth of an inch to the foot in their linear measurement, an allowance known as "shrinkage"—the patternmaker's rule being longer by that quantity than the ordinary engineer's rule. Patterns are usually made of wood, except when the object is intended to be reproduced in great numbers, when brass or iron ones are often used. The more easily fusible alloys, such as pewter, type metal, Britannia metal, etc., are cast in metallic (iron or brass) moulds, which are used indefinitely; but with metals having a higher melting point, a separate mould is required for each cast, metal moulds being only used with these, for the production of ingots or masses that are brought to shape by other means, or when a special quality of surface is required, as in chill casting.

In most cases castings are hollow, the thickness being determined by the empty space included between the mould proper which represents the external surface of the object, and a false mould or core, which may also reproduce a finished surface, as in cylinders, pipes, etc., or be rough and uneven, as in statuary castings, where only the external surface is exposed. The material generally used in moulding from patterns is fine sand, either "green," *i.e.*, slightly damp, or dry, that is, dried by artificial heat—the first method being adopted for all castings of moderate size and weight, while dry sand mouldings are chiefly used for heavy castings where great solidity and strength are required.

The principal requisites of a good foundry sand are fine and uniform grain, a certain amount of cohesiveness without being sticky, infusibility at the temperature of the metal poured, and freedom from combustible or other substances giving off gases when heated. These are best fulfilled by a nearly pure quality of siliceous sand, with at most 3 or 4 per cent. of clay and a slight proportion of hydrated peroxide of iron; the particles when moulded should allow free passage for gases to escape, while perfectly impermeable to the melted metal. Good foundry sands are easily procured in most parts of the United Kingdom, the best being those obtained from reconstructed sandstones in the alluvia of the Thames and other large rivers, and the drift of the New Red Sandstone districts of central England. In other countries not so well provided, foundry sands are often imported or brought from considerable distances inland.

The same sand is used continuously,—the moulds after use being emptied into a pit in the foundry floor, whence the supply for new moulds is taken as required. Fresh sand is added from time to time to make up the waste and to maintain the required plasticity, which diminishes by constant heating. A proportion of ground coal or charcoal is mixed with the sand, so that, although the latter is actually red or brown when fresh, it is reduced to a dark gray or black in the foundry.

The sand forming the mould is held together by an outer frame or box called a flask, as many flasks being used as there are separate parts in the mould. These are united by lugs and cotters, the top one being sometimes loaded when the object is large to prevent it moving under the pressure of the fluid metal. A proper division of the mould is one of the chief points to be attended to in foundry work; where the object is divisible by a central plane into two equal and similar halves, two flasks are usually sufficient; but in complex and irregular forms three, four, or even a larger number are required, its divisions being so arranged that no portion of the pattern overhangs within any section, so that it may be withdrawn by a straight pull without shaking the sand.

The ordinary operation of moulding is as follows. A flask laid with its lugs uppermost is rammed up with old sand to a smooth surface. In this the lower half of the pattern is imbedded, and the surface is covered with dry or facing sand to prevent adhesion. Upon this a second flask is placed, and sand is carefully rammed upon the pattern until the box is completely filled, when the whole is turned over, and the first or false part is emptied, the surface of the upper half smoothed down or faced with sand or finely ground coal or charcoal, and a runner stick, which forms the passage or ingate for the metal, inserted. The second half is then similarly moulded in a second flask, and when finished the upper box is lifted by a crane, leaving the pattern in the lower one or *drag*, from which it is lifted by spikes or rods screwed on temporarily, a slight vibrating motion being set up by striking it rapidly with a piece of wood or iron in order to start it more easily. This is an operation of some nicety, as the blows must be moderate so as not to risk injury to the sand. Provision is made for the exit of gases by piercing vent holes through the sand by a fine wire during ramming. The surface of the mould is finished by dusting it over with charcoal or graphite.

In moulding railway chairs and similar objects of an irregular form required in great numbers, metal patterns are used with loose pieces united by spikes and dove-tails for the overhanging parts, such as the inner faces of the jaws,—the joints being so arranged that the straight parts of the pattern may be withdrawn, leaving the loose parts behind in the mould, whence they are afterwards removed by hand. Fig. 1 represents in section an arrangement of this kind, as applied to moulding railway chairs. The right-hand figure shows the pattern in place with the sand rammed, and the left the mould with the pattern D withdrawn, the loose jaws or "core prints" *a*, *b*, *c*, remaining in the sand, but in such a position as to be easily removed when the flask is turned over. The pattern is withdrawn by a straight pull on the handle H. The stop P gives support to the cores, etc., which represent the trenail holes in the finished casting (fig. 2), and prevent them being dragged away with the pattern, as they might be if left unsupported. The regular descent of the pattern is ensured by the deep sides A and the guides they move in. Usually four patterns are fixed upon one table, so that four chairs are moulded at one operation, the withdrawal of the pattern being effected by lowering the table by a hydraulic press or other mechanical arrangement. The lower mould forming the base of the chair is a nearly flat plate moulded in another machine.

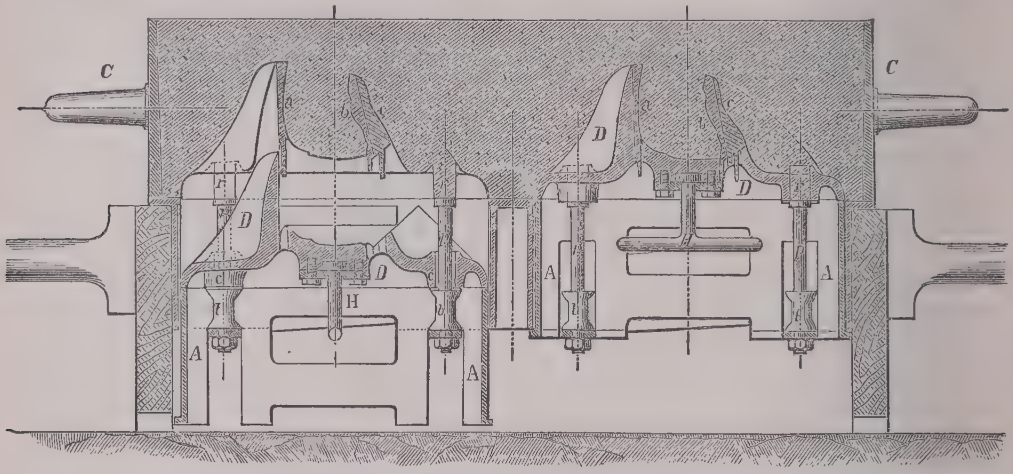

Fig. 1.—Arrangement of Patterns in casting Railway Chairs.

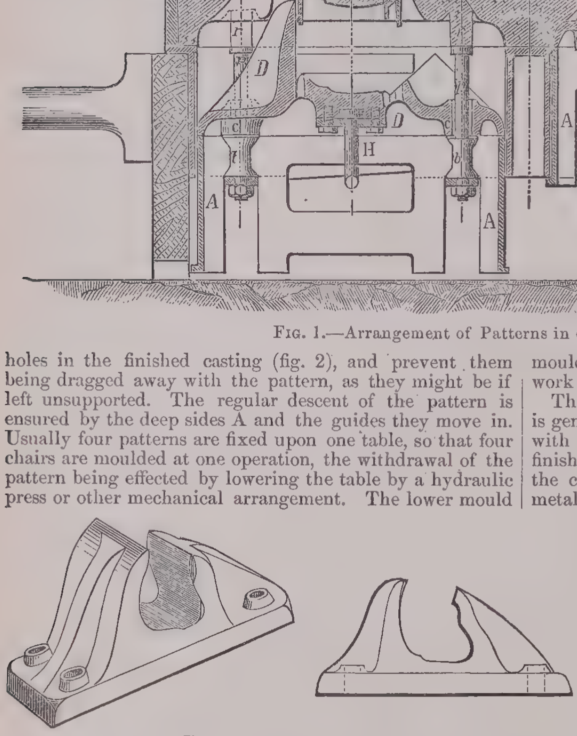

Fig. 2.—Finished Castings.

In loam moulding, as used for large pipes or cylinders, a hollow core of iron or brick is placed in the centre of the foundry, and around it a layer of loam, that is, a mixture of sand and clay rendered plastic by mixture with water, is laid on by trowels and finished up by a revolving template working round a central vertical spindle to the dimension of the interior, forming the "nowel" or core, which when dried is washed with finely ground charcoal and water. Upon this a loam pattern is made up by another template representing the outer surface of the cylinder to the thickness of the finished work. This in like manner is dried and black-washed, and finally a shell of brickwork is built outside, leaving a few inches space between it and the second moulded surface, which is carefully filled up with loam, and forms the "cope" or mould proper. This when dried is lifted by a crane, and either separates from the pattern or "thickness" or drags it away with it, but in either case the latter is broken away, and when the cope is replaced the mould is ready for use as soon as the necessary air-vents, ingates, runner passages, etc., have been provided. In many large foundries, however, gas and water pipes of large size are now produced from permanent moulds of cast iron faced with a thin layer of sand or loam; the outer moulds, being divided into two parts, are brought up to the work and removed by trucks running upon railways.

The method of moulding for bell-founding and statuary is generally similar in principle to that of a loam moulding, with this difference, that the thickness representing the finished object is made up not of loam but of wax, and in the case of statuary, where the object is to use as little metal as possible, it is usually very thin. A plaster cast divided into sections, taken from the original work, forms the matrix within which the wax is moulded of the proper thickness, the inside core being formed of clay with some metal bars to give support, when the work is large. When the plaster mould is removed, the waxen surface is finished up by the sculptor, and the outer mantle or mould proper is formed by coating it with a porous clay mixture. This when dried is carefully baked or burned in a furnace, and the wax melting at the same time leaves the hollow to receive the metal. It is sometimes necessary to leave holes in the casting to allow of the withdrawal of the surface; these are afterwards stopped with plugs of the same metal. Great care is required in the placing of the ingates and runners so as to allow the mould to be regularly and rapidly filled, and prevent any part of the metal setting or chilling before the proper moment.

Melting.—This may be effected either with or without contact with the fuel. In the former case the metal is charged alternately with coke, and occasionally a little flux, into a cylindrical or slightly conical blast furnace known as a cupola, and accumulates in a hollow or sump at the bottom below the tuyeres or blast pipes, whence it is tapped out from time to time, either directly into the mould or more generally into a ladle, for conveyance to the moulds arranged upon the foundry floor. In the second case the fusion takes place either upon the bed of a reverberatory furnace or in crucibles in air furnaces heated by coke or by gaseous fuel. Of these methods the first or cupola is only fitted for iron founding, the reverberatory furnace is used for bronze and iron, and in special forms for steel; while crucible melting is most general for brass and bronze small castings, as well as for the finer kinds of steel, or generally for any metal that is likely to be altered by direct contact with the fuel. The description of these appliances belongs more properly to the article Furnace. The founder's ladle or "shank" is a bucket or cup-shaped vessel of wrought iron lined with a shell of fire-clay, with a lip for pouring, having two projecting handles. One of these is straight and serves as a pivot; the other with a cross bar called a crutch is used as a tipping handle when pouring. When of small size the filled ladle can be carried from the cupola to the work and poured by two men, but when of large size containing several tons of metal they are slung from a crane and tipped by a tangent screw and worm wheel, manipulated by a man standing at a distance. The perfection of ladle arrangement is to be seen in Bessemer's process of steel making, where several tons of melted steel are distributed into a ring of ingot moulds in a circular pit by two or three men in a very few minutes. In Krupp's arrangements for making large steel castings from crucibles an intermediate or equalizing ladle is used. The crucibles, which contain about 70 ℔ each, are drawn from the furnaces in regular order, and poured in such a manner that an uninterrupted stream of metal is kept up from the ladle to the mould.

Large castings when filled from above are liable to be spongy or unsound in the upper part of the mould, or that last filled. In such cases an extra length is given at the top of the mould, as the unsound portion or dead-head is afterwards removed. This plan is usually followed in casting bronze guns. Sound and dense castings can be obtained by filling with a vertical side runner, so that the metal enters the mould from below and solidifies under the hydrostatic head represented by the vertical height of the runner. A method employed by Sir Joseph Whitworth, of applying hydraulic pressure to the metal in the mould until it solidifies, has been adopted with great success by the inventor in the prevention of blow holes and similar imperfections in steel ingots.

In "chill casting" a portion of the surface of the whole or a part of the mould is made of cast iron, so that the metal brought in contact with it is rapidly cooled. It is adopted in the production of Palliser's cast iron projectiles for penetrating armor plates, rolls for boiler and other iron plates, and paper glazing, and in America for hardening the treads of railway wheels. The iron where in contact with the chill surface becomes white, of a platy crystalline structure, and intensely hard, while such portions as are cooled in contact with the sand remain finely granular, dark gray, and comparatively soft. (H. B.)

FOUNDLING HOSPITALS are intended to save children from death by exposure, and it is therefore difficult to describe them properly apart from the general subject of infanticide. This practice was extremely common among nearly all ancient nations. It may still be studied in such horrible institutions of savage life as the Areoi of the Society Islands, or the Meebra of New South Wales; and it may be found in the greatest variety of form among the tribes of Hindustan.[1] The motives which suggested the practice were sometimes superstitious, more often extremely practical. As the natives of Gujarat said to Major Walker, "Pay our daughters' marriage portions, and they shall live." The feeling here was one of social dignity mixed with the strong contempt which many savages express for the single life. But in most cases children were killed simply because the parents, having no realized wealth, did not expect to be able to clothe and feed them. This is especially seen in the frequent killing of female children and those who are sick or deformed. In some places the practice has been confined to the children of concubines, of stranger fathers, or of mothers dying from sickness. In the earliest society the right to kill belonged to the father, sometimes assisted by a person skilled in omens, or by a council of friends. But the usage soon hardened into a binding custom or into express legislation. Thus in the exogamous communities girls were clearly a source, not of weakness only, but of danger. At a much later period the number of a family, or of the daughters, was often fixed by law, and both Lycurgus and the Roman decemvirs directed the slaughter of deformed children. This violence to the domestic affections was probably made easier by the notion which appears in Greek science and in Roman law that neither the fœtus nor the newly-born child is entitled to the privileges of humanity. The Greek pastoral of Longus (*The Loves of Daphnis and Chloe*), and the *Heautontimorumenos* of Terence, show still better than the text of laws how the conscience of a civilized society reconciled itself to such cruelties. And the sober reasoning of Aristotle (*Republic*, vii. c. 16) goes even beyond the custom of his time. Pliny the elder defends infanticide as a necessary check on population, and Quintilian and Seneca bear witness to the frightful mortality among children exposed, and the systematic mutilation of those who survived. Notwithstanding the eloquent protests of the Christian fathers, it was not till the time of Severus and Caracalla that a Roman lawyer ventured to make the noble statement, "Necare videtur non tantum is qui partum perfocat, sed is qui abjicit et qui alimonia denegat, et is qui publicis locis misericordiæ causa exponit quam ipse non habet."[2] The legislation of Constantine did not go beyond a declaration that the killing of a son was parricide, but the famous law of Valentinian, Valens, and Gratian (unusquisque suam sobolem nutriat, C. viii. 52, 2) punished exposure by the loss of the *patria potestas*, and secured the rights of the foster-father. Finally, by Novel 153, Justinian declared that the foundling should no longer be the slave of the foster-father, but should be free. This, however, did not affect western Europe, where social disorder and the recurrence of famine led to extensive sales of children. Against this evil, which was noticed by several councils, the church provided a rough system of relief, children being deposited (*jactati*) in marble shells at the church doors, and tended first by the *matricularii* or male nurses, and then by the *nutricarii* or foster-parents.[3] Nothing is known of the brephotrophia which are said to have existed in the Eastern empire at this time nor of the public tables (such as Velleiana, Bœbiana) which particular emperors are said to have provided for the support of children. The earlier traditions of a hospital at the Cynosarges in Athens and at the Columna Lactaria in the vegetable market at Rome are disputed. It is in the 7th and 8th centuries that definite institutions for foundlings are established in such towns as Trèves, Milan, and Montpellier. In the 15th century Garcias, archbishop of Valentia, is a conspicuous figure in this charitable work; but his fame is entirely eclipsed by that of St. Vincent de Paul, who in the reign of Louis XIII., with the help of the countess of Joigny, Mme. le Gras, and other religious ladies, rescued the foundlings of Paris from the horrors of a primitive institution named La Couche (Rue St. Landry), and ultimately obtained from Louis XIV. the use of the Bicêtre for their accommodation. Letters patent were granted to the Paris hospital in 1670. The Hôtel-Dieu of Lyons was the next in importance. No provision, however, was made outside the great towns; the houses in the cities were overcrowded and administered with laxity; and in 1784 Necker prophesied that the state would yet be seriously embarrassed by this increasing evil.[4] From 1452 to 1789 the law had imposed on the *seigneurs de haut justice* the duty of succoring children found deserted on their territories. The first constitutions of the Revolution undertook as a state debt the support of every foundling. For a time premiums were given to the mothers of illegitimate children, the "enfants de la patrie." By the law of 12 Brumaire, An II., "Toute recherche de la paternité est interdite," while by art. 341 of the Code Napoléon, "la recherche de la matérnité est admise."

France.—The present laws of France relating to this part of what is called L'Assistance Publique are the decree of January, 1811, the instruction of February, 1823, the decree of 5th March, 1852, and the law of 5th May, 1869. These laws carry out the general principles of the law of 7th Frimaire, An V., which completely decentralized the system of national poor relief established by the Revolution. The "enfants assistés" include, besides orphans and foundlings proper, infants brought by their parents into the asylum, and those born in lying-in hospitals and left there by their mothers, children of persons undergoing a judicial sentence, children temporarily taken in while their parents are in the hospital, and an increasing number of children, legitimate, illegitimate, and orphans, who are supported by a system of out-door relief. The asylum which receives them is a departmental and not a communal institution. The state pays only the cost of inspection and superintendence. There remain the "home" expenses, for the nurse (nourrice sédentaire), washing and clothes; and the "out-door" expenses, which include (1) temporary assistance to unmarried mothers in order to prevent desertion; (2) allowances to the foster-fathers (pères nourriciers) in the country for board, school money, etc.; (3) clothing; (4) travelling money for nurses and children; (5) printing, etc.; and (6) expenses in time of sickness and for burials and apprentice fees. In 1868 the total cost was 11,300,171 frs., of which 2,570,171 frs. were paid by the regular foundling asylums, and 8,730,000 frs. by the departments and communes. This represented the support of 67,000 children. In 1828 there were 112,730 children supported at a cost of 9,794,737 frs. The decrease is attributed partly to out-door relief and partly to the suppression of the "tours," of which there were 235 in 1812, and only 25 in 1860. No payments are made for the children after the age of twelve. They are generally apprenticed to a peasant or artisan, and until majority they remain under the guardianship of the administrative commissioners of the department. These commissioners are about to receive a representative character, the councils of the communes and the department, the chambers of commerce, and the chief religious communities receiving a right of nomination, as well as the prefect who represents the state. The ministry of marine have a legal claim to the services of male foundlings, which is seldom exercised. The *droit de recherche* is conceded to the parent on payment of a small fee. The decree of 1811 contemplated the repayment of all expenses by a parent reclaiming a child. The same decree directed a "tour" or revolving box (*Drehcylinder* in Germany) to be kept at each hospital. These have been gradually discontinued. The "Assistance Publique" of Paris is specially provided for by the law of 10th January, 1849. The management consists of a "directeur" appointed by the minister of the interior, and associated with a representative "conseil de surveillance." The Paris Asylum for Enfants Trouvés, with a small branch at Forges, contains about 700 beds. It receives about 4200 children in the year, or nearly one-seventh of the whole annual supply in France; and the total average cost of each child for twelve years is said to be only 1500 frs. There is also in Paris (43 Rue de Journelles) a private charity called *Œuvre de l'Adoption* for the adoption of poor children and orphans. Among the better known school farms which receive children from the hospitals at very small rates of board are those of M. Fournet at Montagny near Chalon-sur-Saône, and of l'Abbé Vedey at Varaignes in the Dordogne. It is impossible here to give even a sketch of the long and able controversies which have occurred in France on the principles of management of foundling hospitals, the advantages of "tours" and the system of admission *à bureau ouvert*, the transfer of orphans from one department to another, the free communication between parent and child, the hygiène and service of hospitals and the inspection of nurses, the education and reclamation of the children and the rights of the state in their future. Reference may be made to the work of Terme and Montfalcon noticed at the end of this article.

---

[1] Compare Moore on *Hindu Infanticide*, 1811, with Brown on *Infanticide in India*, 1868. In Baluchistan, where children are often drowned in milk, there is a euphemistic proverb, "The lady's daughter died drinking milk."

[2] See *Julius Paulus, sive de partus expositione et nece apud veteres*, by Gerard Noodt, 1700, criticised by Bynkershoek, *De Jure occidendi, vendendi, et exponendi liberos apud Romanos*, 1719.

[4] *De l'Administration des Finances*, iii. 136; see also the article "Enfant Exposé" in Diderot's *Encyclopédie*, 1755, and Chamousset's *Mémoire politique sur les Enfants*, 1757.

Belgium.—In this country the arrangements for the relief of foundlings and the appropriation of public funds for that purpose very much resemble those in France, and can hardly be usefully described apart from the general questions of local government and poor law administration. The Commissions des Hospices Civiles, however, are purely communal bodies, although they receive pecuniary assistance from both the departments and the state. A decree of 1811 directed that there should be an asylum and a wheel for receiving foundlings in every arrondissement. The last "wheel," that of Antwerp, was closed in 1860. The present law of 30th July, 1834, distinguishes foundlings born of unknown parents from infants abandoned by known parents. Of the former the cost is divided between commune and province; of the latter the cost falls entirely on the *domicile de secours*. The law of 1834 directs that the state budget shall contain an annual foundling subsidy, which is distributed among the provinces. The suppression of the "wheels" is supposed to have reduced the subsidy from 94,608 frs. to 50,000 frs. in 1873, and the number of foundlings from 7703 in 1849 to 5745 in 1860. The great mass of the foundlings are in Brabant, that is, in Brussels, which in 1872 paid out nearly 300,000 frs. on their account. In the Netherlands many of the foundlings are sent to the "beggar colonies,"—agricultural, spinning, and weaving establishments introduced in 1810 in imitation of the French *dépôts de mendicité*. They also resemble the Flemish *écoles agricoles de réforme*. (See *Des Institutions de Bienfaisance et de Prévoyance en Belgique, 1850 à 1860*, par M. P. Lentz.)

Italy is very rich in foundling hospitals, pure and simple, orphans and other destitute children being separately provided for. Piedmont has 18, making an annual expenditure of 1,084,000 frs.; Genoa has 6, with an expenditure of 350,000 frs.; Lombardy has 13, with an expenditure of 1,468,000 frs.; and the Emilia has 15, with an expenditure of 833,000 frs. In 1870 the gross expenditure in Italy on foundlings alone was 8,044,754 frs., more than twice the sum expended on pauper lunatics. The law concerning charitable works (3d August, 1862) contemplates the erection of a charity board in every commune. At present both the communal council and the provincial deputation have certain rights of control over charitable administration. (See *Della Carita Preventiva in Italia*, by Signor Fano.) In Rome one branch of the St. Spirito in Sassia (so called from the Schola Saxonum built in 728 by King Ina in the Borgo) has, since the time of Pope Sixtus IV., been devoted to foundlings. For ten years before 1869 the annual average of children admitted was 1141, of whom 382 were ascertained to be illegitimate and 300 legitimate, the rest uncertain. The average annual number of foundlings supported is 3268, the average annual deaths 981. The death-rate in the hospital is said to be 88·78; in the country at the nursing houses 12·80. The *Conservatory* is for the support of foundling girls who after passing through the hospital do not get settled in life. The whole institution costs 305,603 frs. per annum. (See *The Charitable Institutions of Rome*, by Cardinal Morichini.) In Naples the foundling hospital is called "L'Annunziata." It receives yearly about 2000 "figli della Madonna," as they are called. It must not be confounded with the more famous Albergo Reclusorio, or Seraglio dei Poveri, which is an ordinary charity for the education of children and the maintenance of infirm old persons. The chief house at Florence is called "degli Innocenti;"[1] at Genoa the "Pammatome;" at Milan, "Santa Caterina alla ruota." In Venice the Casa degli Esposti or foundling hospital, founded in 1346, and receiving 450 children annually, was recently separated from the "Riunione di Instituti Pii," and placed under provincial administration. The splendid legacy of the last doge, Ludovico Manin, is applied to the support of about 160 children by the "Congregazione di Carita" acting through 30 parish boards (deputatione fraternate).

Austria.—In Austria foundling hospitals occupied a very prominent place in the general instructions which, by rescript dated 16th April, 1781, the emperor Joseph II. issued to the charitable endowment commission. Acting under the advice of Count Boucquoy, the author of *The Neighborly Love Association*, which supplied first Bohemia and then the empire with a type of poor law administration, the emperor provided for the case of destitute children before proceeding to deal with the cases of destitute sick and infirm poor. This class of children includes, besides foundlings proper, the children born in lying-in hospitals of unmarried women, and the children of unmarried women who can show that they have been suddenly confined when on their way to the lying-in hospital, and even in some cases legitimate children whose parents are prevented by illness or other temporary cause from maintaining them, and orphans when below the age required for admission to a regular orphanage. In 1818 these foundling asylums and the lying-in houses were declared to be state institutions. They were accordingly supported by the state treasury until the fundamental law of 20th October, 1860, handed them over to the provincial committees. They are now local institutions, depending on provincial funds, and are quite separate from the ordinary parochial poor institute. Admission is gratuitous when the child is actually found on the street, or is sent by a criminal court, or where the mother undertakes to serve for four months as nurse or midwife in an asylum, or produces a certificate from the parish priest and "poor-father" (the parish inspector under the Boucquoy scheme) that she has no money. In other cases payments of 30 to 100 florins are made. When two months old the child is sent for six or ten years to the houses in the neighborhood of respectable married persons, who have certificates from the police or the poor-law authorities, and who are inspected by the latter and by a special medical officer. These persons receive a constantly diminishing allowance, and the arrangement may be determined by 14 days' notice on either side. The foster-parents may retain the child in their service or employment till the age of twenty-two, but the true parents may at any time reclaim the foundling on reimbursing the asylum and compensating the foster-parents. The enlightened principles of the rescript of 1781, with regard to the general and technical education of the children, do not seem to be carried out in practice. It is said that there are in the empire 35 foundling hospitals, receiving annually 120,000 children.

Turkey.—Under the Greek system of vestry relief, which works very efficiently at Constantinople, a large sum is spent on foundlings. There is no hospital, but the children are brought before the five members (ἐπίτροποι) of the vestry (fabrique) or parish church committee, who, acting as the *coumbaros* or god-father, board out the child with some poor family for a small monthly payment, and afterwards provide the child with some sort of remunerative work.

Russia.—Under the old Russian system of Peter I. foundlings were received at the church windows by a staff of women paid by the state. But since the reign of Catherine II. the foundling hospitals have been in the hands of the provincial officer of public charity (prykaz obshestvennago pryzrenya). The great central institutions (Vospitatelnoi Dom), at Moscow and St. Petersburg (with a branch at Gatchina) were founded by Catherine. When a child is brought the baptismal name is asked, and a receipt is given, by which the child may be reclaimed up to the age of ten. The mother may nurse her child. After the usual period of six years in the country very great care is taken with the education, especially of the more promising children. Of the 26,000 sent annually to these two houses from all parts of Russia, only 25 per cent. are said to reach majority. The hospital is still, however, a valuable source of recruits for the public service. Malthus (*The Principles of Population*, vol. i. p. 434) has made a violent attack on these Russian charities. He argues that they discourage marriage and therefore population, and that the best management is unable to prevent a high mortality. He adds: "An occasional child murder from false shame is saved at a very high price if it can be done only by the sacrifice of some of the best and most useful feelings of the human heart in a great part of the nation." It does not appear, however, that the rate of illegitimacy in Russia is comparatively high; it is so in the two great cities. The rights of parents over the children were very much restricted, and those of the Government much extended by a ukase issued by the emperor Nicholas in 1837. The most eminent Russian writer on this subject is M. Gouroff. See his *Recherches sur les Enfants Trouvés*, and *Essai sur l'histoire des Enfants Trouvés*, Paris, 1829.

---

[1] For the history of the Misericordia and Bigallo (White Cock), founded by the Brothers of Mercy, see Horner's *Walks in Florence*, vol. i.

In *America* the foundling hospitals are chiefly private charities. There is a large one called the *Cuna* in the city of Mexico. The house for girls at Rio de Janeiro is once a year frequented by men in want of wives, each application being considered by the managers. In Brazil there are several houses of mercy for foundlings, and exposures are often made at the doors of private houses. The foundling asylum of the sisters of charity in New York was opened in 1869. In 1873 it received 1124 infants not three weeks old. The annual cost is 115,000 dollars. A crib is placed in the vestibule at night, and the name and date of birth are generally left with the child.

Great Britain.—The Foundling Hospital of London was incorporated by Royal Charter in 1739 "for the maintenance and education of exposed and deserted young children." The petition of Captain Thomas Coram, who is entitled to the whole credit of the foundation,[1] states as its objects "to prevent the frequent murders of poor miserable children at their birth, and to suppress the inhuman custom of exposing new-born infants to perish in the streets." At first no questions were asked about child or parent, but a distinguishing mark was put on each child by the parent. These were often marked coins, trinkets, pieces of cotton or ribbon, verses written on scraps of paper. The clothes, if any, were carefully recorded. One entry is, "Paper on the breast, clout on the head." The applications became too numerous, and a system of balloting with red, white, and black balls was adopted. In 1756 the House of Commons came to a resolution that all children offered should be received, that local receiving places should be appointed all over the country, and that the funds should be publicly guaranteed. A basket was accordingly hung outside the hospital; the maximum age for admission was raised from two to twelve months, and a flood of children poured in from the country workhouses. In less than four years 14,934 children were presented, and a vile trade grew up among vagrants of undertaking to carry children from the country to the hospital,—an undertaking which, like the French *meneurs*, they often did not perform, or performed with great cruelty. Of these 15,000 only 4400 lived to be apprenticed out. The total expense was about £500,000. This alarmed the House of Commons. After throwing out a bill which proposed to raise the necessary funds by fees from a general system of parochial registration, they came to the conclusion that the indiscriminate admission should be discontinued. The hospital, being thus thrown on its own resources, adopted a pernicious system of receiving children with considerable sums (*e. g.*, £100), which sometimes led to the children being reclaimed by the parent. This was finally stopped in 1801; and it is now a fundamental rule that no money is received. The committee of inquiry must now be satisfied of the previous good character and present necessity of the mother, and that the father of the child has deserted it and the mother, and that the reception of the child will probably replace the mother in the course of virtue and in the way of an honest livelihood. The principle is in fact that laid down by Fielding in *Tom Jones*—"Too true I am afraid it is that many women have become abandoned and have sunk to the last degree of vice by being unable to retrieve the first slip." At present the hospital supports about 500 children up to the age of fifteen. The average annual number of applications is 236, and of admissions 41. The children used to be named after the patrons and governors, but the treasurer now prepares a list. After three years in the country the children come back to town. At sixteen the girls are generally apprenticed as servants for four years, and the boys at the age of fourteen as mechanics for seven years. There is a small benevolent fund for adults. The hospital has an income of above £11,000, which will be enormously increased in 1895, when the leaseholds of the Lamb's Conduit grounds expire. From the famous chapel built by Jacobsen in 1747 the hospital derives a net income of £500. The musical service, which was originally sung by the blind children only, was made fashionable by the generosity of Handel, who frequently had the "Messiah" performed there, and who bequeathed to the hospital a MS. copy (full score) of his greatest oratorio. The altar-piece is West's picture of Christ presenting a little Child. In 1774, Dr. Burney and Signor Giardini made an unsuccessful attempt to form in connection with the hospital a public music school, in imitation of the Conservatorium of the Continent. In 1847, however, the present successful "Juvenile Band" of about 30 boys was started. The educational effects of music have been found excellent, and the hospital supplies many musicians to the best army and navy bands. The early connection between the hospital and the eminent painters of the reign of George II. is one of extreme interest. The exhibitions of pictures at the Foundling, which were organized by the Dilettanti Club, undoubtedly led to the formation of the Royal Academy in 1768. Hogarth painted a portrait of Captain Coram for the hospital, which also contains his March to Finchley, and Roubiliac's bust of Handel. Coram, the founder, was remarkable for the versatility of his public spirit. He did much for the development of Georgia and Nova Scotia. (See *History and Objects of the Foundling Hospital, with Memoir of its Founder*, by J. Brownlow, 3d ed., 1865.)

In 1704 the Foundling Hospital of Dublin was opened. No inquiry was made about the parents, and no money received. From 1500 to 2000 children were received annually. A large income was derived from a duty on coal and the produce of car licenses. In 1822 an admission fee of £5 was charged on the parish from which the child came. This reduced the annual arrivals to about 500. In 1829 the select committee on the Irish miscellaneous estimates recommended that no further assistance should be given. The hospital had not preserved life or educated the foundlings. The mortality was nearly 4 in 5, and the total cost £10,000 a year. Accordingly, in 1835, Lord Glenelg (then Irish Secretary) closed the institution.

Scotland never seems to have possessed a foundling hospital. In 1759, John Watson left funds which were to be applied to the pious and charitable purpose "of preventing child murder" by the establishment of a hospital for receiving pregnant women and taking care of their children as foundlings. But by an Act of Parliament in 1822, which sets forth "doubts as to the propriety" of the original purpose, the money was given to trustees to erect a hospital for the maintenance and education of destitute children. The fundamental difference between Scotland and most other Protestant countries on the one hand, and those Catholic countries which have adopted the Code Napoléon on the other, is that in the former proceedings for aliment may be taken against the putative father. Hence the mother is not helpless. She cannot, however, in Scotland deposit her bastard in the poorhouse, unless she herself is entitled to relief and prepared to go there; and relief is of course given only so long as the mother is not able to support herself. An infant absolutely deserted would of necessity be taken care of by the poor law authority. It is in Scotland a crime at common law to "expose" a young child to the risk of death or to any serious danger; and it is also an offence against the Poor Law Act of 1845 for either the mother or the putative father (who has acknowledged the paternity) to desert an illegitimate child. In England the offence is defined as the abandoning or exposing a child under the age of two, whereby its life is endangered, or its health is, or is likely to be, permanently injured (24 and 25 Vict. c. 100, § 27). Besides this the provisions of the Industrial Schools Acts apply to a large proportion of the cases of homeless and deserted children which in other countries might be entrusted to the foundling hospitals. And indeed the system of boarding out pauper children seems to have realized most of the advantages promised by the hospital. The disagreeable feature of the Scotch practice is the number of women who, without any feeling of shame, get a family of illegitimate children by different fathers, whom they attack in succession for aliment. The rate of illegitimacy in some Scotch counties has reached 14, 15, and 16 per cent. It is not likely, however, that the hospital principle, though cured of its worst fault, that of secret admission without inquiry,[2] will ever be received in Great Britain or Ireland. The key-note of public opinion on the question was probably struck by Lord Brougham in his *Letters to Sir Samuel Romilly on the Abuse of Charities*, and by Dr. Chalmers in his *Christian Economy of Large Towns*. The true solution, however, depends less on abstract political reasoning than on prudent management of existing institutions. In France, for instance, a great fund of practical skill in administration has been accumulated. In Great Britain the evil may be more safely left to private charity and religious effort. If fewer women fall there, there is perhaps a profounder degradation of those who do.

The following are the most important systematic works on this subject: *Histoire Statistique et Morale des Enfants Trouvés*, by MM. Terme et Montfalcon, Paris, 1837. The authors were eminent medical men at Lyons, connected with the administration of the foundling hospital. Remacle, *Des Hospices d'Enfants Trouvês en Europe*, Paris, 1838. Hügel, *Die Findelhäuser und das Findelwesen Europas*, Vienna, 1863. Emminghaus, "Das Armenwesen und die Armengesetzgebung," in *Europäischen Staaten*, Berlin, 1870. An English translation of part of this book was published in 1873, by Mr. E. B. Eastwick, M. P., in the interests of the Charity Organization Society, but it does not contain the German editor's European statistics. Some recent information may also be got in the Reports on Poor Laws in Foreign Countries, communicated to the Local Government Board by the Foreign Secretary. *Accounts and Papers*, 1875, vol. 65, c. 1225. See also the well-informed articles by MM. Esquiros and de Marisy, in vols. xiii. and liv. of the *Revue des Deux Mondes*. The references to Montesquieu, *Esprit des Lois*, xxiii. 22, and to Voltaire, *Dict. Phil.*, article "Charité," are more of literary than of practical interest. (W. C. S.)

---

[1] Addison had suggested such a charity (*Guardian*, No. 3).

[2] As M. de Marisy has said, the *Enfant trouvé* exists no longer; he has been replaced by the *Enfant assisté*.

FOUNTAIN, a spring of water. The term is applied in a restricted sense to such springs as, whether fed by natural or artificial means, have arrangements of human art at a point where the water emerges. Pure water is so necessary to man, and the degree of plenty, constancy, and purity in which it is procured, transported, prepared for use, and distributed in populous districts is so fair a standard of civilization, that it hardly seems unreasonable in Pausanias to put it among the criteria, asking, with reference to Panopæus, if that can rightly be called a city which has neither ruler, gymnasium, forum, nor fountain of water. Among the Greeks we learn, mainly from Pausanias, that fountains were very common in the cities; and springs being very plentiful in Greece, little engineering skill was required to convey the water from place to place. Receptacles of sufficient size were made for it at the springs; and to maintain its purity, structures were raised inclosing and covering the receptacle.

It is not surprising that so beneficent an object as a spring of water should be connected with religious belief. It is certain that until modern times fountains have been in some way connected with the religion of the people among whom they sprang, and dedicated to one or other of its personalities. In Greece they were dedicated to gods and goddesses, nymphs and heroes, and were frequently placed in or near temples. The references to fountains by Pausanias are frequent, but he gives no full descriptions. That of Pirene at Corinth (mentioned also by Herodotus) was formed of white stone, and contained a number of cells from which the pleasant water flowed into an open basin. Legend connects it with the nymph Pirene, who shed such copious tears, when bewailing her son who had been slain by Diana, that she was changed into a fountain. The city of Corinth possessed many fountains. In one near the statues of Diana and Bellerophon, the water flowed through the hoofs of the horse Pegasus. The fountain of Glauce, inclosed in the Odeum, was dedicated to Glauce, because she was said to have thrown herself therein, believing that its waters could counteract the poisons of Medea. Another Corinthian fountain had a bronze statue of Neptune standing on a dolphin from which the water flowed. The fountain constructed by Theagenes at Megara was remarkable for its size and decorations, and for the number of its columns. One at Lerna was surrounded with pillars, and the structure contained a number of seats affording a cool summer retreat. Near Pharæ was a grove dedicated to Apollo, and in it a fountain of water. Pausanias gives a definite architectural detail when he says that a fountain at Patræ was reached from without by descending steps. Mystical, medicinal, surgical, and other qualities, as well as supernatural origin, were ascribed to fountains. One at Cyanæ near Lycia was said to possess the quality of endowing all persons descending into it with power to see whatever they desired to see; while the legends of fountains and other waters with strange powers to heal are numerous in many lands. The fountain Enneacrunus at Athens was called Callirrhoe before the time the water was drawn from it by the nine pipes from which it took its later name. Two temples were above it, according to Pausanias, one dedicated to Demeter and Proserpine, and the other to Triptolemus. The fountain in the temple of Erechtheus at Athens was supplied by a spring of salt water, and a similar spring supplied that in the temple of Poseidon Hippias at Mantinea.

Though no doubt most tribes of other than nomadic habits of life must have contrived, in their settlements, appliances of some kind for maintaining the supply of water constant and pure, very few remains of these have been found that possess any degree of architectural importance. Layard mentions an Assyrian fountain, found by him in a gorge of the river Gomel, which consists of a series of basins cut in the solid rock, and descending in steps to the stream. The water had been originally led from one to the other by small conduits, the lowest of which was ornamented by two rampant lions in relief.

The water-supply of Rome and the works auxiliary to it were on a scale to be expected from a people of such great practical power. The remains of the aqueducts which stretched from the city across the Campagna are amongst the most striking monuments of Italy. Vitruvius (book viii.) gives minute particulars concerning the methods to be employed for the discovery, testing, and distribution of water, and describes the properties of different waters with great care, proving the importance which was attached to these matters by the Romans. The aqueducts supplied the baths and the public fountains, from which last all the populace, except such as could afford to pay for a separate pipe to their houses, obtained their water. These fountains were therefore of large size and numerous. They were formed at many of the *castella* of the aqueducts (see AQUEDUCT.) According to Vitruvius, each *castellum* should have three pipes,—one for public fountains, one for baths, and the third for private houses. Considerable revenue was drawn from the possessors of private water-pipes. The Roman fountains were generally decorated with figures and heads. Fountains were often also the ornament of Roman villas and country houses; in those so situated the water generally fell from above into a large marble basin, with at times a second fall into a still lower receptacle.

To the remains of Pompeii we are indebted for much exact knowledge of Roman antiquity in its minutest particulars; and not the least interesting of the disinterred forms are those of the public and private fountains which the city possessed. Two adjacent houses in Pompeii had very remarkable fountains. "One," says Gell, "is covered with a sort of mosaic consisting of vitrified tesseræ of different colors, but in which blue predominates. These are sometimes arranged in not inelegant patterns, and the grand divisions as well as the borders are entirely formed and ornamented with real sea-shells, neither calcined by the heat of the eruption nor changed by the lapse of so many centuries" (*Pompeiana*, i. 196). Another of large size was similarly decorated with marine shells, and is supposed to have borne two sculptured figures, one of which, a bronze, is said to be in the museum at Naples. This fountain projects 5 feet 7 inches from the wall against which it is placed, and is 7 feet wide in front, while the height of the structure up to the eaves of the pediment is 7 feet 7 inches. On a central column in the piscina was a statue of Cupid, with a dove, from the mouth of which water issued. Cicero had, at his villa at Formiæ, a fountain which was decorated with marine shells.

Fountains were very common in the open spaces and at the crossways in Pompeii. They were supplied by leaden pipes from the reservoirs, and had little ornament except a human or animal head, from the mouth of which it was arranged that the water should issue. Not only did simple running fountains exist, but the remains of *jets d'eau* have been found; and a drawing exists representing a vase with a double jet of water, standing on a pedestal placed in what is supposed to have been the impluvium of a house. There was also a *jet d'eau* at the eastern end of the peristyle of the Fullonica at Pompeii.

As among the Greeks, so with the early Celts, traces of superstitious beliefs and usages with relation to fountains can be traced in monumental and legendary remains. Near the village of Primaleon in Brittany was a very remarkable monument,—one possibly unique, as giving distinct proof of the existence of an ancient cult of fountains. Here, according to Freminville, is a dolmen composed of a horizontal table supported by two stones only, one at each end. All the space beneath this altar is occupied by a long square basin formed of large flat stones, which receives a fountain of water. At Lochrist is another vestige of the Celtic cult of fountains. Beneath the church, and at the foot of the hill upon which it is built, is a sacred fountain, near which is erected an ancient chapel, which with its ivy-covered walls has a most romantic appearance. A Gothic vault protects this fountain. Miraculous virtues are still attributed to its water, and on certain days the country people still come with offerings to draw it (see La Poix de Freminville, *Antiquités de la Bretagne*, i. 101). In the enchanted forest of Brochelande, so famous from its connection with Merlin, was the fountain of Baranton, which was said to possess strange characteristics. Whoever drew water from it, and sprinkled the steps therewith, produced a tremendous storm of thunder and hail, accompanied with thick darkness.

The Christian missionaries could not easily overcome beliefs so planted in the heart of the people, and so strengthened by daily practices. By a wise stroke, whether of policy or instinct, finding themselves unable to eradicate the superstitions which ascribed miraculous power to rocks and woods, streams and fountains, and connected them with the divinities of the old religions, they changed their form and direction by dedicating these objects to the Virgin and to saints, so making the force of the old belief an instrument for its own overthrow.

Fountains were attached to the new religion by the erection of statues of the Virgin or of saints upon the possibly rude structures that collected the water and preserved its purity. There is some uniformity in the architectural characteristics of these structures during the Middle Ages. A very common form in rural districts was that in which the fountain was reached by descending steps (*fontaine grotte*). A large basin received the water, sometimes from a spout, but often from the spring itself. This basin was covered by a sort of porch or vault, with at times moulded arches and sculptured figures and escutcheons. On the bank of the Clain at Poitiers is a fountain of this kind, the Fontaine Joubert, which though restored in 1597 was originally a structure of the 14th century. This kind of fountain is frequently decorated with figures of the Virgin or of saints, or with the family arms of its founder; often, too, the water is the only ornament of the structure, which bears a simple inscription. A large number of these fountains are to be found in Brittany and indeed throughout France, and the great antiquity of some of them is proved by the superstitions regarding them which still exist amongst the peasantry. A form more common in populous districts was that of a large open basin, round, square, polygonal, or lobed in form, with a columnar structure at the centre, from the lower part of which it was arranged that spouts should issue, playing into an open basin, and supplying vessels brought for the purpose in the cleanest and quickest manner. The columns take very various forms, from that of a simple regular geometrical solid, with only grotesque masks at the spouts, to that of an elaborate and ornate Gothic structure, with figures of virgins, saints, and warriors, with mouldings, arches, crockets, and finials. At Provins there is a fountain said to be of the 12th century, which is in form an hexagonal vase with a large column in the centre, the capital of which is pierced by three mouths, which are furnished with heads of bronze projecting far enough to cast the water into the basin. In the public market-place at Brunswick is a fountain of the 15th century, of which the central structure is made of bronze. Many fountains are still existing in France and Germany which, though their actual present structure may date no earlier than the 15th or 16th century, have been found on the place of, and perhaps may almost be considered as restorations of, pre-existing fountains. Except in Italy few fountains are of earlier date than the 14th century. Two of that date are at the abbey of Fontaine Daniel, near Mayenne, and another, of granite, is at Limoges. Some of these Middle Age fountains are simple, open reservoirs inclosed in structures which, however plain, still carry the charm that belongs to the stone-work of those times. There is one of this kind at Cully, Calvados, walled on three sides, and fed from the spring by two circular openings. Its only ornamentation is a small empty niche with mouldings. At Lincoln is a fountain of the time of Henry VIII., in front of the church of St. Mary Wickford. At Durham is one of octangular plan, which bears a statue of Neptune.

The decay of architectural taste in the later centuries is shown by the fountain of Limoges. It is in form a rock representing Mount Parnassus, upon which are carved in relief Apollo, the horse Pegasus, Philosophy, and the Nine Muses. At the top Apollo, in 16th century costume, plays a harp. Rocks, grass, and sheep fill up the scene.

About the earliest drawing of any drinking fountain in England occurs in Moxon's *Tutor to Astronomie and Geography* (1659): it is "surmounted by a diall, which was made by Mr. John Leak, and set upon a composite column at Leadenhall corner, in the majoralty of Sir John Dethick, Knight." The water springs from the top and base of the column, which stands upon a square pedestal and bears four female figures, one at least of which represents the costume of the period. This fountain is referred to and a copy of the engraving given in Chambers's *Book of Days*. The public drinking fountains in towns and villages are now very common and quite secular objects. In the East they are a very important institution. In Cairo alone there are 300. These "sebeels" are not only to be seen in the cities, but are plentiful in the fields and villages, and the great number of them endowed for the gratuitous supply of water to the passengers is referred to by Lane as proving the possession by the Egyptians of a benevolent and charitable character.

Purely ornamental fountains and jets d'eau are found in or near many large cities, royal palaces, and private seats. The Fontana di Trevi, at Rome, is very large and very celebrated, but from an artistic point of view about as bad work as could possibly be conceived. It was erected early in the last century under Pope Clement XII., and has all the characteristics of decadence. La Fontana Paolina and those in the piazza of St. Peter's are perhaps next in celebrity to that of Trevi, and are certainly in better taste. At Paris, the Fontaine des Innocens (the earliest) and those of the Place Royal, of the Champs Élysées, and of the Place de la Concorde are the most noticeable. The fountain of the lions and other fountains in the Alhambra Palace are, with their surroundings, a very magnificent sight. The largest *jets d'eau* are those at Versailles, at the Sydenham Crystal Palace, and at San Ildefonso. With the exception of the last, these are supplied from artificial elevated reservoirs.

For information regarding the geological conditions which cause natural springs and aid in the formation of artificial ones, see ARTESIAN WELLS. (W. HE.)

FOUNTAINS ABBEY. See ABBEY, vol. i. p. 25.

FOUQUÉ, FRIEDRICH HIENRICH KARL, BARON DE LA MOTTE (1777–1843), one of the most industrious and popular of German authors in the early part of this century, was born February 12, 1777, at Brandenburg on the Havel. The family of De la Motte Fouqué was, as the name suggests, of French extraction, but had been driven from France by the revocation of the edict of Nantes; and Fouqué's grandfather, having entered the Prussian army, rose to the rank of general, and became the friend of Frederick the Great. Fouqué's father, at one time an officer of dragoons, lived, at the date of the boy's birth, in retirement at Brandenburg; and his mother, who died in 1788, was a daughter of the Hofmarschall von Schlegell of Dessau. The little Friedrich, godson and namesake of the great king, was brought up in the neighborhood of Potsdam, first at his father's estate Sacro, and afterwards at Lentzke, a property to which they removed when he was nine years old. An only child, he was educated at home by a succession of tutors, one of whom, the author August Hülse, did much to encourage the boy's literary tastes. The somewhat monotonous home life, also, was relieved by holidays spent with relations in a romantic old castle near Halle, and by brilliant visits to Potsdam, whence he came with his little head turned by glimpses of the revered king, by blasts of military music and the tramp of soldiers. When the French Revolution broke out, the young Fouqué eagerly espoused the cause of the royal family. He became discontented with the prospect of studying law at the university of Halle, and in 1794 entered the army as *über-completer Cornet* in the grand-duke of Weimar's cuirassier regiment, then in the field. At the age of nineteen he served in the unfortunate campaign of the Rhine; and for several years afterwards he led a half military half literary life with his regiment, whose headquarters were first at Aschersleben and then at Bückeburg.

Fouqué married very early in life; but the union was an unhappy one and ended in divorce. In 1802, when still only twenty-five, he married his second wife, the widowed Frau von Rochow, better known as Caroline, Baroness de la Motte Fouqué, herself an authoress of some note; and, having obtained his discharge from military service, he retired to his wife's family estate of Nennhausen, near Rathenau, devoting himself to the study of Italian and Spanish, and to bringing out his first work *Dramatische Spiele*, under the feigned name of Pellegrin (1804). The volume was published by the brothers Schlegel, and their names were enough to win popularity for what Fouqué himself afterwards called a "Schülerwerk." It was followed by *Romanzen aus dem Thal Ronceval*, and by two plays, the *Falk* and the *Reh*, which appeared simultaneously. Cheered by praise from the brothers Schlegel, Fouqué set to work with renewed vigor, and in 1806 published a metrical rendering of an old prose romance, the *Historie vom edlen Ritter Galmy, und einer schönen Herzogin von Bretagne.* In the same year appeared the poem *Schiller's Todtenfeier*, the joint work of Bernhardi and Fouqué, who still wrote under the name of Pellegrin; and in 1808 he published *Alwin*, a romance in 2 vols. This won for him many literary admirers, perhaps the chief of whom was Jean Paul Friedrich Richter. *Sigurd der Schlangentödter* (published 1808) was founded on the story of the Nibelungenlied, and formed the first of a collection which appeared in 1818 under the title *Heldenspiele. Sigurd* was the first work published in Fouqué's own name. In 1811 appeared a play, *Eginhard und Emma*, two volumes entitled *Vaterländische Schauspiele*, and the chivalric romance *Der Zauberring.* Conjointly with Frau von Helvig of Heidelberg he issued a *Taschenbuch der Sagen und Legenden* (1812–13), and with his friend Wilhelm Neumann began a periodical called *Die Musen* (1812–14). Another collection of plays, *Schauspiele für Preussen*, was published in 1813, and in 1814 *Corona*, a poem, and *Der Todesbund*, a romance, forming the first of a series in six separate volumes entitled *Kleine Romane* (1814–19). In the same year (1814) he published a series in four parts entitled the *Jahreszeiten*, the spring number of which contained his romance *Undine*, the summer number *Die beiden Hauptleute*, the autumn number *Aslauga's Ritter* and *Algin und Jucunda*, and the winter number *Sintram und seine Gefährten. Die Fahrten Thiodolfs des Isländers*, another story of chivalry, appeared in 1814, and was considered by Fouqué himself to be one of his most successful works. In 1816 he translated a tragedy, *Numancia*, from the Spanish of Cervantes, and published also *Der Sängers Liebe, Karl's des Grossen Geburt und Jugendsjahre*, and a tragedy called the *Pilgerfahrt.* Meanwhile in February, 1813, he had rejoined the army as lieutenant of cavalry, and twice narrowly escaped with his life at the battle of Lützen. After the battle, while he was carrying an important dispatch over country at night, his horse stumbled into deep water; and this misadventure resulted in an illness which disabled him for further service. He received an honorable discharge, was presented with the decoration of the "Johanniterorden," and promoted to the rank of major of cavalry. The invalided soldier now returned to his wife and daughter at Nennhausen, and again took up his pen. His wife died in 1831; and, having removed to Halle, he married there for the third time. He delivered lectures in Halle on the history of poetry and other forms of literature, and had gone to Berlin with the purpose of lecturing there also, when he died suddenly, January 23, 1843, aged 66.

The following is a list of his publications from 1817 downwards:—*Die Wunderbaren Fahrten des Grafen Alethes von Lindenstein* (1817); *Altsächsische Bildersaal* (1818–20); *Der Mord Augusts von Kotzebue: Freundesruf an Deutschlands Jugend* (1819); *Bertrand du Guesclin* (1821); *Hieronymus von Stauf* (1821); *Der Verfolgte, Wilde Liebe*, and *Ritter Elidone* (1822); *Refugié, oder Heimath und Fremde: ein Roman aus der neuen Zeit* (1824); *Lebensbeschreibungen des Konigl. Preuss. Generals der Infanterie, H. A. Baron de la Motte Fouqué* (1824); a collection of his poems in 5 vols., containing most of his lyrics and dramas (1816–27); *Geschichte der Jungfrau von Orleans* (1826); *Der Sängerkrieg auf der Wartburg* (1828); *General v. Rüchel, eine militärische Biographie* (1828); *Fata Morgana* (1830); *Erzählungen u. Novellen* (1833); *Die Weltreiche* (1835–40); *Büchlein von der Liebeslehre* (1837); *Der Pappenheimer Cuirassier* (1842); *Lebensgeschichte des Baron Friedrich de la Motte Fouqué, aufgezeichnet durch ihn selbst* (1840); *Goethe und Einer seiner Bewunderer* (1840); *Ausgewählte Werke des Baron Fr. de la Motte Fouqué, Ausgabe letzter Hand* (1841). A posthumous romance, entitled *Abfall und Busse, oder die Seelenspiegel,—ein Roman aus der Grenzscheide das 18 und 19 Jahrh.*, was published in 1844; also a collection entitled *Geistliche Gedichte* (1858), and *Christlicher Liederschatz* (1862).

Fouqué's popularity was great; but he had the misfortune to outlive it. A disciple of the brothers Schlegel and the Romance School in Germany, he became one of its most illustrious representatives. There was a time when Fouqué's volumes were in every German household, and people waited eagerly at the libraries for his newest work. But he lived to see the change in literary taste which shelved the romance school, and with it almost all his own writings. The greater part of these are being now quickly forgotten. Those which have survived, and will survive, the variations of popular taste, are his romances—the *Zauberring* and the contents of the *Jahreszeiten*, especially the exquisite *Undine*, which has always been considered his masterpiece. Fouqué's was not an intellect of the very highest order, neither was he a man of intense feelings; and those who expect to find in his works deep thinking or highly-wrought passion will be disappointed. Should they, however, desire the graceful, the romantic, the exquisite, it is there in abundance. They will find a beauty and simplicity of style unsurpassed in the German language; plots, light and airy, laid in scenes of opal hue. For Fouqué aimed at ethereal beauty, delighted in word-painting, and flitted continually between the glories of a crimson Spanish sunset and the cold steel-blue of a north German nightfall. There is in his works plenty of sweet pathos, of a kind which may wet the eye but never wrings the heart; there is also a truly German love of the weird and supernatural; but their especial characteristic is their pure, chivalric tone:—"An ideal of Christian knighthood," says the translator of *Wilhelm Meister*, in his *German Romance*, "whencesoever borrowed or derived, has all along, with more or less distinctness, hovered round his fancy." It is in allusion to this same characteristic that Jean Paul Richter, Fouqué's illustrious critic in the *Heildelberger Jahrbücher*, has christened him "Der Tapfere," or "The Valiant."

Of Fouqué's works, the *Undine*, the *Zauberring*, *Aslauga's Ritter*, and *Sintram* have been translated into English. The translation of *Aslauga's Ritter* is in Carlyle's *German Romance*. (F. M.)

FOUQUET, Nicolas (1615–1680), viscount of Melun and of Vaux, marquis of Belle-Isle, superintendent of finance under Louis XIV., was born at Paris in 1615. Destined to official life, he was carefully educated; and so evident was his superior ability that he was appointed master of requests at the age of twenty. He was only thirty-five when he obtained the important post of *procureur-général* to the parliament of Paris (1650). During the civil war Fouquet devoted himself to the interests of the queen-mother, Anne of Austria, and enjoyed in return her protection and patronage. At her instance he was called in 1652 to the office of superintendent of finance. The finances were then in a state of the utmost disorder, from the long wars and the shameless greed of courtiers and officials; and it is stated that Fouquet for a time provided the means of meeting the expenses of the state out of his own fortune or by loans obtained on his own credit. He had long been in the confidence of the first minister, Cardinal Mazarin, and was his zealous instrument. But soon after the marriage of Louis XIV. a quarrel broke out between them, and thenceforth each was bent on injuring the other. The increasing deficit in the treasury alarmed the king; inquiries were addressed to Colbert, who was secretly ambitious of succeeding Fouquet as minister of finance, and he consequently made the worst of the case against Fouquet. The extravagant expenditure and personal display of the superintendent served to intensify the ill-will of the king. Fouquet had bought the port of Belle-Isle, and strengthened its fortifications, with a view to taking refuge there in case of disgrace. He had spent enormous sums in building a palace on his estate of Vaux, which in its extent, magnificence, and splendor of decoration, was almost a forecast of Versailles. He had cherished the hope of succeeding Mazarin as first minister, and had even made advances to Mademoiselle de la Vallière. In August, 1661, he entertained the king at his palace of Vaux, giving him a fête unrivalled for magnificence, at which *Les Fâcheux* of Molière was for the first time produced. But the king could not be appeased. By crafty devices Fouquet had been induced to sell his office of *procureur-général*, thus losing the protection of its privileges, and he had paid the price of it into the treasury. The king, however, was only prevented from arresting him at the fête by the pleading of the queen mother. He dissembled for a short time, and the arrest was made about three weeks later at Nantes. Fouquet, after several removals from prison to prison, was sent to the Bastille. His trial extended over several years, and excited the deepest interest. In 1664 he was condemned and sentenced to perpetual exile and confiscation of his property. The sentence, however, was commuted into one of imprisonment for life in the fortress of Pignerol. He bore his fate with manly fortitude, and composed in prison several devotional works. He died at Pignerol March 23, 1680. The report of his trial was published in Holland, in 15 vols., in 1665–1667, in spite of the remonstrances which Colbert addressed to the states-general. A second edition, under the title of *Œuvres de M. Fouquet*, appeared in 1696.

FOUQUIER-TINVILLE, Antoine Quentin (1747–1795), was born at Hérouel, a village in the department of the Aisne. Originally a *procureur* (attorney) attached to the châtelet jurisdiction at Paris, he is said to have been driven by his debts to accept a humble employment under the lieutenant-général de police. When the Revolution broke out he was, as the friend of Danton and Robespierre, appointed public prosecutor to the revolutionary tribunal of Paris, and discharged this office with the most unimpassioned rigor from the 10th of March, 1793, to the 28th of July, 1794. He dealt as pitilessly with his friends as with his enemies, if only they were charged by the committee of public safety. He sent to the guillotine his protector Danton, just as he had sent Vergniaud and the Girondists. He was not an eloquent speaker, but maintained his accusations with an obstinacy so cold, convincing, and pressing that he never failed to obtain from the judges the sentence of capital punishment, which he always claimed. Although it seems that he had been somewhat unscrupulous in the earlier part of his career, he was, during the period of his bloody mission, inaccessible to bribery; and, having accepted it as his business to provide the guillotine with a constant supply of victims, he might well boast of faithfulness in its discharge. And this he actually did in the pamphlet that he published in his own defence, when he had been imprisoned by order of the convention (August 1, 1794), on the motion of Fréron, whose hands had been as deeply imbrued in blood as those of Fouquier. But the men then in power wielded the terrors of the law in a spirit of revenge that made them as unsparing as Robespierre and his companions had been. After a trial which lasted forty-one days, Fouquier-Tinville was in his turn sent to the scaffold, on the 8th of May, 1795.

See *Mémoire pour A. Q. Fouquier, ex-accusateur public près le tribunal révolutionnaire établi à Paris, et rendu volontairement à la Conciergerie le jour du décret qui ordonne son arrestation*, Paris, 1794, 4to; A. J. T. Berriat-Saint-Prix, *La Justice révolutionnaire à Paris, Bordeaux, Brest, Lyons, Nantes, etc.*, Paris, 1861, 18mo; E. Campardon, *Histoire du Tribunal révolutionnaire de Paris*, Paris, 1861, 2 vols. 18mo (the 2d edition, Paris, 1866, 2 vols. 8vo, has a slightly altered title, *Tribunal révolutionnaire de Paris*); Mortimer-Ternaux, *Histoire de la Terreur d'après les documents authentiques et des pièces inédites*, Paris, 1861, etc., 8 vols. 8vo.

FOURCHAMBAULT, a town of France in the department of Nièvre, on the right bank of the Loire, with a station on the railway about 5 miles S.E. of Nevers. It owes its importance to its extensive iron-works, which were established in 1821 by MM. Boignes, and give employment to from 2000 to 5000 workmen. Among the more remarkable *chefs d'œuvre* which have been produced at Fourchambault are the metal portions of the Pont du Carrousel, some of the bronzes of the Colonne du Juillet, the framework of the cathedral at Chartres, and the vast spans of the bridge over the Dordogne at Cubzac. The population of the town in 1871 was 5835, and of the commune 6054.

FOURCROY, Antoine François, Comte de (1755–1809), a celebrated chemist, son of an apothecary in the household of the duke of Orleans, was born at Paris, June 15, 1755. Some of his ancestors had been distinguished at the bar, but the branch of the family to which he belonged had become greatly reduced in circumstances. At the age of fourteen Fourcroy left the college at Harcourt, where he had profited but little by the instruction of a harsh teacher. Deterred by the ill-success of a friend from going upon the stage, he for two years maintained himself as a copyist and writing-master; he then, in consequence of unjust treatment there received, left the office of his employer. At this juncture, Vicq d'Azyr, who having boarded at his home had become acquainted with the young man's talents, encouraged him to enter upon a medical career. We accordingly now behold Fourcroy a poor and hard-working student of medicine, his lodging a garret, in the middle only of which was it possible to stand upright, and his near neighbor a water-carrier, to whose family of twelve he acted as physician, receiving for his services a good supply of water. To support himself he gave lessons to other students, and made translations for a bookseller, who 30 years later, when Fourcroy had become director-general of public instruction, conscientiously offered to make up for the meagreness of his former remuneration. In 1777, under the auspices of the Société Royale de Médecine, appeared Fourcroy's first publication, *Essai sur les Maladies des Artisans*, the translation of a Latin work by Ramazzini, with notes and additions. At length Fourcroy, who was recognized as the most successful alumnus of the Parisian medical school, became an applicant for a gratuitous degree and license, provision for the granting of which to the best deserving poor student had been made by the bequest of a Dr. Diest. It so happened that the faculty of physic at Paris entertained feelings of the most jealous enmity against the newly-founded Société Royale de Médecine, of which Vicq d'Azyr was perpetual secretary, and to humiliate him, and in him the whole society, it rejected his protégé Fourcroy. Upon this the society itself subscribed the fees requisite for a diploma (£250), which was obtained by Fourcroy in 1780; but as the degree of "docteur regent" was unanimously refused, it was impossible for him to procure any professorship under the faculty. However, in 1784 his reputation as a chemist gained for him, although Berthollet was his fellow candidate, the lectureship of chemistry at the college of the Jardin du Roi, which had become vacant by the death of Macquer, one of the last of the phlogistic school. This post he continued to hold for the next 25 years; and so great were the crowds which his eloquence attracted that it was twice necessary to enlarge his lecture-theatre. Fourcroy was one of the first converts to the theories of Lavoisier, which he designated "La Chimie Française," a name which, as Thomson remarks (*History of Chemistry*, ii. p. 130), "certainly contributed more than anything else to give the new notions currency, at least in France." Together with Berthollet, Fourcroy was associated with Lavoisier and Guyton de Morveau in 1786 and 1787 in the preparation of a work entitled *Méthode de Nomenclature Chimique*, published in the latter year. In 1785 a memoir on the tendons, subsequently completed in six parts, gained for him admission into the French Academy of Sciences. He became in 1792 one of the deputies of the National Convention, and in 1793 a member of the Assembly, and soon proved himself one of the most active of the committee for the public instruction. To him was due the enlargement of the Jardin des Plantes, and the formation of a commission for the preservation of works of art. He further was the means of releasing from imprisonment Desault, surgeon of the Hôtel-Dieu, and of preventing the execution of Darcet, though, unfortunately for science, he found no opportunity of rescuing Lavoisier. On the 9th of Thermidor he was appointed a member of the committee for the public safety, and in this capacity he instituted three schools of medicine, assisted in the organization of the École Polytechnique (at that time the École des Travaux Publiques), and was concerned also in the establishment of the École Normale, the Institut, and the Musée d'Histoire Naturelle. After the revolution of the 9th November, 1799, he was made a councillor of state; and, being appointed director-general of instruction, he in the course of 5 years superintended the formation of 12 schools of law, over 30 lyceums, afterwards called royal colleges, and 300 elementary schools. His incessant labors at length told on his health, and he suffered greatly from palpitation of the heart. On the 16th December, 1809, the very day on which by letters patent he had been created a count of the French empire, with a yearly pension of 20,000 francs, he was signing some despatches when he suddenly exclaimed "Je suis mort," and with those words expired.

Among the separate publications of Fourcroy are *Leçons élémentaires d'Histoire naturelle, et de Chimie*, 2 vols. 8vo, 1782, enlarged, after several editions, to 10 vols. 8vo, with the title *Système des Connaissances chimiques*, 6 vols. 4to, 1801–2; *Mémoires et Observations de Chimie*, 8vo, 1784; *L'Art de connaître et d'employer les Médicamens dans les Maladies*, 2 vols. 8vo, 1785; *Essai sur le Phlogistique et les Acides*, 8vo, 1788, from the English of Kirwan, with notes by De Morveau and De Fourcroy; *Philosophie Chimique, ou Vérités fondamentales de la Chimie moderne*, 8vo, 1795, perhaps his best work, of which several editions and translations appeared; *Notice sur la Vie et* *les Travaux de Lavoisier*, 8vo, 1796; *Tableaux synoptiques de Chimie*, 4to, 1800; *Discours sur l'Instruction publique*, 8vo, 1802. He was the author of more than 160 papers on chemical subjects, contributed to the *Mémoires* of the Academy and the Institute, the *Annales de Chimie*, and the *Annales de Musée d'Histoire Naturelle*, and was editor of *Le Médecin Éclairé*. The more important of his later researches were published jointly in his own name and that of Vanquelin, whom he befriended, and was the means of first bringing into notice.

See Palissot de Beauvois, *Éloge Historique*, 1810; G. Cuvier, "Éloge Historique," *Mém. de l'Inst.*, 1810, pp. xcvi.–cxxviii., and *Ann. Mus. Hist. Nat.*, xvii. 1811, pp. 99–132; Thomson, *Annals*, i. 1818.

FOURIER, FRANÇOIS CHARLES MARIE (1772–1837), one of the most celebrated socialist writers, was born at Besançon in Franche-Comté, on the 7th April, 1772. His father was a draper in good circumstances, and Fourier received an excellent education at the college in his native town. After completing his studies there he travelled for some time in France, Germany, and Holland. On the death of his father he inherited a considerable amount of property, which, however, was lost when Lyons was besieged by the troops of the Convention. Being thus deprived of his means of livelihood, Fourier entered the army, but after two years' service as a chasseur was discharged on account of ill-health. In 1803 he published a remarkable article on European politics which attracted the notice of Napoleon, some of whose ideas were foreshadowed in it. Inquiries were made after the author, but nothing seems to have come of them. After leaving the army Fourier entered a merchant's office in Lyons, and some years later undertook on his own account a small business as broker. He obtained in this way just sufficient to supply his wants, and devoted all his leisure time to the elaboration of his first work on the organization of society.

During the early part of his life, and while engaged in commerce, he had become deeply impressed with the conviction that social arrangements resulting from the principles of individualism and competition were essentially imperfect and immoral. He proposed to substitute for these principles co-operation or united effort, by means of which full and harmonious development might be given to human nature. The scheme, worked out in detail in his first work, *Théorie des Quatre Mouvements* (2 vols., Lyons, 1808, published anonymously), has for foundation a particular psychological proposition and a special economical doctrine. Psychologically Fourier held what may with some laxity of language be called natural optimism,—the view that the full, free development of human nature or the unrestrained indulgence of human passion is the only possible way to happiness and virtue, and that misery and vice spring from the unnatural restraints imposed by society on the gratification of desire. This principle of harmony among the passions he regarded as his grandest discovery—a discovery which did more than set him on a level with Newton, the discoverer of the principle of attraction or harmony among material bodies. Throughout his works, in uncouth, obscure, and often unintelligible language, he endeavors to show that the same fundamental fact of harmony is to be found in the four great departments,—society, animal life, organic life, and the material universe. In order to give effect to this principle and obtain the resulting social harmony, it was needful that society should be reconstructed; for, as the social organism is at present constituted, innumerable restrictions are imposed upon the free development of human desire. As practical principle for such a reconstruction Fourier advocated co-operative or united industry. In many respects what he says of co-operation, in particular as to the enormous waste of economic force which the actual arrangements of society entail, still deserves attention, and some of the most recent efforts towards extension of the co-operative method, *e.g.*, to house-keeping, were in essentials anticipated by him. But the full realization of his scheme demanded much more than the mere admission that co-operation is economically more efficacious than individualism. Society as a whole must be organized on the lines requisite to give full scope to co-operation and to the harmonious evolution of human nature. The details of this reorganization of the social structure cannot be given briefly, but the broad outlines may be thus sketched. Society, on his scheme, is to be divided into departments or *phalanges*, each *phalange* numbering about 1600 persons. Each *phalange* inhabits a *phalanstère* or common building, and has a certain portion of soil allotted to it for cultivation. The *phalanstères* are built after a uniform plan, and the domestic arrangements are laid down very elaborately. The staple industry of the *phalanges* is, of course, agriculture, but the various *series* and *groupes* into which the members are divided may devote themselves to such occupations as are most to their taste; nor need any occupation become irksome from constant devotion to it. Any member of a group may vary his employment at pleasure, may pass from one task to another. The tasks regarded as menial or degrading in ordinary society can be rendered attractive if advantage is taken of the proper principles of human nature: thus children, who have a natural affinity for dirt, and a fondness for "cleaning up," may easily be induced to accept with eagerness the functions of public scavengers. It is not, on Fourier's scheme, necessary that private property should be abolished, nor is the privacy of family life impossible within the phalanstère. Each family may have separate apartments, and there may be richer and poorer members. But the rich and poor are to be locally intermingled in order that the broad distinction between them, which is so painful a feature in actual society, may become almost imperceptible. Out of the common gain of the phalange a certain portion is deducted to furnish to each member the minimum of subsistence; the remainder is distributed in shares to labor, capital, and talent,—five-twelfths going to the first, four-twelfths to the second, and three-twelfths to the third. Upon the changes requisite in the private life of the members Fourier was in his first work more explicit than in his later writings. The institution of marriage, which imposes unnatural bonds on human passion, is of necessity abolished; a new and ingeniously constructed system of license is substituted for it. Considerable offence seems to have been given by Fourier's utterances with regard to marriage, and generally the later advocates of his views are content to pass the matter over in silence, or to veil their teaching under obscure and metaphorical language.

The scheme thus sketched attracted no attention when the *Théorie* first appeared, and for some years Fourier remained in his obscure position at Lyons. In 1812 the death of his mother put him in possession of a small sum of money, with which he retired to Bellay in order to perfect his second work. The *Traité de l'Association Agricole Domestique* was published in 2 vols. at Paris in 1822, and a summary appeared in the following year. After its publication the author proceeded to Paris in the hope that some wealthy capitalist might be induced to attempt the realization of the projected scheme. Disappointed in this expectation, he returned to Lyons. In 1826 he again visited Paris, and as a considerable portion of his means had been expended in the publication of his book, he accepted a clerkship in an American firm. In 1829 and 1830 appeared what is probably the most finished exposition of his views, *Le Nouveau Monde Industriel*. In 1831 he attacked the rival socialist doctrines of St. Simon and Owen in the small work *Piéges et Charlatanisme de deux Sectes, St. Simon et Owen*. His writings now began to attract some attention. A small body of adherents gathered around him, and the most ardent of them, Victor Considérant, published in 1834 his *Destinée Sociale*, undoubtedly the most able and most important work of the Fourierist school. In 1832 a newspaper, *Le Phalanstère ou la Réforme Industrielle*, was started to propagate the views of the school, but its success was not great. In 1833 it declined from a weekly to a monthly, and in 1834 it died of inanition. It was revived in 1836 as *Le Phalange*, and in 1843 became a daily paper, *La Democratie Pacifique*. In 1850 it was suppressed.

Fourier did not live to see the success of his newspaper, and the only practical attempt during his lifetime to establish a phalanstère was a complete failure. In 1832 M. Baudet Dulary, deputy for Seine-et-Oise, who had become a convert, purchased an estate at Condé sur Vesgre, near the forest of Rambouillet, and proceeded to establish a socialist community. The capital supplied was, however, inadequate, and the community broke up in disgust. Fourier was in no way discouraged by this failure, and till his death, in October, 1837, lived in daily expectation that wealthy capitalists would see the merits of his scheme, and be induced to devote their fortunes to its realization. It may be added that subsequent attempts to establish the phalanstère have been uniformly unsuccessful.

For an examination of the principles on which Fourier's socialist scheme is based, reference must be made to the general articles COMMUNISM and SOCIALISM, but a word must be added as to the character of the man and his works. Fourier seems to have been of extremely retiring and sensitive disposition. He mixed little in society, and appeared, indeed, as if he were the denizen of some other planet. Of the true nature of social arrangements, and of the manner in which they naturally grow and become organized, he must be pronounced extremely ignorant. The faults of existing institutions presented themselves to him in an altogether distorted manner, and he never appears to have recognized that the evils of actual society are immeasurably less serious than the consequences of his arbitrary scheme. Out of the chaos of human passion he supposed harmony was to be evolved by the adoption of a few theoretically disputable principles, which themselves impose restraints even more irksome than those due to actual social facts. With regard to the economic aspects of his proposed new method, it is of course to be granted that co-operation is more effective than individual effort, but he has nowhere faced the question as to the probable consequences of organizing society on the abolition of those great institutions which have grown with its growth. His temperament was too ardent, his imagination too strong, and his acquaintance with the realities of life too slight to enable him justly to estimate the merits of his fantastic views. That this description of him is not expressed in over-strong language must be clear to any one who not only considers what is true in his works—and the portion of truth is by no means a peculiar discovery of Fourier's,—but who takes into account the whole body of his speculations, the cosmological and historical as well as the economical and social. No words can adequately describe the fantastic nonsense which he pours forth, partly in the form of general speculation on the universe, partly in the form of prophetic utterances with regard to the future changes in humanity and its material environment. From these extraordinary writings it is no extreme conclusion that there was much of insanity in Fourier's mental constitution.

FOURIER, JEAN BAPTISTE JOSEPH (1768–1830), French mathematician, was born at Auxerre, March 21, 1768. He was the son of a tailor, and was left an orphan in his eighth year; but through the kindness of a friend, who observed in him the promise of superior abilities, admission was gained for him into the military school of his native town, which was then under the direction of the Benedictines of Saint-Maur. He soon distinguished himself as a student, and made rapid progress, delighting most of all, but not exclusively, in mathematics. It was his wish to enter the artillery or engineer corps, but failing in this, he was appointed professor of mathematics in the school in which he had been a pupil. This post he held for about four years (1789–1794), and during this time he was frequently called to lecture on other subjects, rhetoric, philosophy, and history. On the institution of the normal school at Paris he was sent to teach in it, and was afterwards attached to the polytechnic school. Fourier was one of the savants who accompanied Bonaparte to Egypt in 1798; and during this expedition he was called to discharge important political duties in addition to his scientific ones. He was for a time virtually governor of half Egypt, was for three years secretary of the institute of Cairo, and undertook to deliver the funeral orations for Kléber and Desaix. On his return to France he was nominated prefect of Grenoble, and was created baron and chevalier of the Legion of Honor. He took an important part in the preparation of the famous *Description de l'Egypte*, and wrote the historical introduction. He held his prefecture for 14 years; and it was during this period that he carried on his elaborate and fruitful investigations on the propagation of heat in solid bodies. His first memoir on the mathematical theory of heat was crowned by the Academy. On the return of Napoleon I. from Elba in 1815, Fourier published a royalist proclamation, and left Grenoble as Napoleon entered it. He was then deprived of his prefecture, and, although immediately named prefect of the Rhône, was soon after again deprived. He now settled at Paris, was elected to the Academy of Sciences in 1816, but in consequence of the opposition of Louis XVIII. was not admitted till the following year, and was afterwards made perpetual secretary in conjunction with Cuvier. In 1822 he published his most celebrated work, entitled, *La Théorie Analytique de la Chaleur*, which by its new methods and great results made an epoch in the history of mathematical and physical science. Of this work M. Cousin said that the grandeur of its results was no more to be questioned than their certainty, and that in the opinion of scientific Europe the novelty of the analysis on which they rest is as evident as its completeness. In 1827 Fourier was received at the French Academy, and the same year succeeded Laplace as president of the council of the polytechnic school. In 1828 he became a member of the Government commission established for the encouragement of literature. He died at Paris, May 16, 1830. After his death appeared his remarkable work entitled *Analyse des équations determinées*, which was written in his youth and left unfinished. It was completed and edited by M. Navier in 1831. In addition to the works above mentioned, Fourier wrote many memoirs on scientific subjects, and *éloges* of distinguished men of science.

FOURMONT, ÉTIENNE (1683–1745), a French Orientalist, was born at Habelai, near St. Denis, in 1683. He studied in Mazarin College, and afterwards in the seminary of Trente-trois. Here his attention was attracted to Oriental languages, and shortly after leaving the seminary he published a *Traduction du Commentaire du Rabbin Abraham Aben Esra sur l'Ecclésiaste*. He subsequently studied at Navarre, and in 1705 brought out *Nouvelle Critique Sacrée*, which gained him the notice of the professors of the Sorbonne. In 1711 Louis XIV. appointed Fourmont to assist a young Chinese, Hoan-ji, in compiling a Chinese grammar, and notwithstanding that Hoan-ji died in 1716, Fourmont persevered alone at the task assigned him, and published in 1737 *Meditationes Sinicæ*, and in 1742 *Grammatica Sinica*. Besides numerous other works connected with Oriental literature, he is the author of *Réflexions Critiques sur les Histoires des Anciens Peuples*, Paris, 1735, and several dissertations printed in the *Mémoires* of the Academy of Inscriptions. He became professor of Arabic in the Royal College in 1715. In 1713 he was elected a member of the Academy of Inscriptions, in 1738 a member of the Royal Society of London, and in 1741 a member of that of Berlin. He died at Paris in December, 1745. He must not be confounded with Michel Fourmont (1690-1746), his youngest brother, who also was a member of the Academy of Inscriptions, was professor of the Syriac language in the Royal College, and was sent by the Government to copy inscriptions in Greece.

FOURNIER, PIERRE SIMON (1712–1768), French engraver and type-founder, was born at Paris, September 15, 1712. He was the son of a printer, and was brought up to his father's business. After studying drawing under the painter Colson, he practised for some time the art of wood-engraving, and ultimately turned his attention to the engraving and casting of types. He designed many new characters, and his foundry became celebrated not only in France but in foreign countries. Not content with his practical achievements, he sought to stimulate public interest in his art by the production of various works on the subject. In 1737 he published his *Table des Proportions qu'il faut observer entre les Caractères*, which was followed by several other technical treatises. In 1758 he assailed the title of Guttenberg to the honor awarded him as inventor of printing, claiming it for Schöffer, in his *Dissertation sur l'Origine et les Progrès de l'Art de graver en Bois*. This gave rise to a controversy in which Schöpflin and Baer were his opponents. Fournier's contributions to this debate were collected and reprinted under the title of *Traités historiques et critiques sur l'Origine de l'Imprimerie*. His principal work, however, was the *Manuel Typographique*, which appeared in 2 vols. 8vo in 1764, the first volume treating of engraving and type-founding, the second of printing, with examples of different alphabets. It was the author's design to complete the work in four volumes, but he did not live to execute it. He died at Paris, October 8, 1768.

FOWL (Danish *Fugl*, German *Vogel*), originally used in the sense that Bird[1] now is, but, except in composition,—as Sea-Fowl, Wild-Fowl, and the like,—practically almost confined[1] at present to designate the otherwise nameless species which struts on our dunghills, gathers round our barn-doors, or stocks our poultry yards—the type of the genus *Gallus* of ornithologists, of which four well-marked species are known. The *first* of these is the Red Jungle-Fowl of the greater part of India, *G. ferrugineus*,—called by many writers *G. bankiva*,—which is undoubtedly the parent stock of all the domestic races (*cf.* Darwin, *Animals and Plants under Domestication*, i. pp. 233-246). It inhabits Northern India from Sindh to Burmah and Cochin China, as well as the Malay Peninsula and many of the islands as far as Timor, besides the Philippines. It occurs on the Himalayas up to the height of 4000 feet, and its southern limits in the west of India proper are, according to Jerdon, found on the Raj-peepla hills to the south of the Nerbudda, and in the east near the left bank of the Godavery, or perhaps even further, as he had heard of its being killed at Cummum. This species greatly resembles in plumage what is commonly known among poultry-fanciers as the "Black-breasted Game" breed, and this is said to be especially the case with examples from the Malay countries, between which and examples from India some differences are observable—the latter having the plumage less red, the ear-lappets almost invariably white, and slate-colored legs, while in the former the ear-lappets are crimson, like the comb and wattles, and the legs yellowish. If the Malayan birds be considered distinct, it is to them that the name *G. bankiva* properly applies. This species is said to be found in lofty forests and in dense thickets, as well as in ordinary bamboo-jungles, and when cultivated land is near its haunts, it may be seen in the fields after the crops are cut in straggling parties of from 10 to 20. The crow to which the cock gives utterance morning and evening is described as being just like that of a Bantam, but never prolonged as in some domestic birds. The hen breeds from January to July, according to the locality; and lays from 8 to 12 creamy-white eggs, occasionally scraping together a few leaves or a little dry grass by way of a nest. The so-called *G. giganteus*, formerly taken by some ornithologists for a distinct species, is now regarded as a tame breed of *G. ferrugineus* or *bankiva*. The *second* good species is the Gray Jungle-Fowl, *G. sonnerati*, whose range begins a little to the northward of the limits of the preceding, and it occupies the southern part of the Indian peninsula, without being found elsewhere. The cock has the shaft of the neck-hackles dilated, forming a horny plate, the terminal portion of which is like a drop of yellow sealing-wax. His call is said to be very peculiar, being a broken and imperfect kind of crow, quite unlike that of *G. ferrugineus*, and impossible, says Jerdon, to describe. The two species, where their respective ranges overlap, occasionally interbreed in a wild state, and the present readily crosses in confinement with domestic poultry, but the hybrids are nearly always sterile. The *third* species is the Cingalese Jungle-Fowl, *G. stanleyi* (the *G. lafayettii* of some authors), peculiar to Ceylon. This also greatly resembles in plumage some domestic birds, but the cock is red beneath, and has a yellow comb with a red edge, and purplish-red cheeks and wattles. He has also a singularly different voice, his crow being dissyllabic. This bird crosses readily with tame hens, but the hybrids are believed to be infertile. The *fourth* species, *G. varius* (the *G. furcatus* of some authors), inhabits Java and the islands eastward as far as Flores. This differs remarkably from the others in not possessing hackles, and in having a large unserrated comb of red and blue, and only a single chin wattle. The predominance of green in its plumage is another easy mark of distinction. Hybrids between this species and domestic birds are often produced, but they are most commonly sterile. Some of them have been mistaken for distinct species, as those which have received the names of *G. æneus* and *G. temmincki*.

---

[1] *Bird* (cognate with *breed* and *brood*) was originally the young of any animal, and an early Act of the Scottish parliament speaks of "Wolf-birdis," *i.e.*, Wolf-cubs.

Several circumstances seem to render it likely that Fowls were first domesticated in Burmah or the countries adjacent thereto, and it is the tradition of the Chinese that they received their poultry from the West about the year 1400 B.C. By the Institutes of Manu, the date of which is variously assigned from 1200 to 800 B.C., the tame Fowl is forbidden, though the wild is allowed to be eaten—showing that its domestication was accomplished when they were written. The bird is not mentioned in the Old Testament nor by Homer, though he has Ἀλέκτωρ (Cock) as the name of a man, nor is it figured on ancient Egyptian monuments. Pindar mentions it, and Aristophanes calls it the Persian bird, thus indicating it to have been introduced to Greece through Persia, and it is figured on Babylonian cylinders between the 6th and 7th centuries B.C. It is sculptured on the Lycian marbles in the British Museum (*circa* 600 B.C.), and Blyth remarks (*Ibis*, 1867, p. 157) that it is there represented with the appearance of a true Jungle-Fowl, for none of the wild *Galli* have the upright bearing of the tame breed, but carry their tail in a drooping position. For further particulars of these breeds see POULTRY. (A. N.)

FOWLER, CHARLES (1792–1867), architect, was born at Collumpton, Devon, May 17, 1792. After serving an apprenticeship of five years at Exeter, he went to London in 1814, and entered the office of David Laing, where he remained till he commenced practice for himself. His first work of importance was the Court of Bankruptcy in Basinghall Street, finished in 1821. Although he gained in the following year the first premium for a design for the new London bridge, a design by another architect was ultimately agreed upon and carried out. Among Fowler's other designs for bridges is that for the one constructed across the Dart at Totness. He was also the architect for the markets of Covent Garden and Hungerford, the new market at Gravesend, and Exeter lower market; and besides several churches he designed Devon lunatic asylum (1845), the London fever hospital (1849), and the hall of the Wax Chandlers' Company, Gresham Street (1853). For some years he was honorary secretary of the institute of British architects, and he was afterwards created vice-president. He retired from his profession in 1853, and died at Great Marlow, Bucks, September 26, 1867.

FOWLER, JOHN (1826–1864), inventor of the steam plough, was born at Melksham, Wilts, July 11, 1826. He learned practical engineering at Middlesborough-on-Tees, and in 1849 invented a machine for laying drain tiles, which was at first worked by horses, but afterwards by steam. In 1852 he began experiments in steam cultivation, and at the Chester meeting in 1858 he received for his steam plough the Royal Agricultural Society's prize of £500. In conjunction with two partners he established in 1861, at Leeds, the well known firm of Fowler & Co. He died 4th December, 1864. See AGRICULTURE.

FOWLER, WILLIAM (*c.* 1560–1614), one of the poets who frequented the court of James VI. before his accession to the throne of England, was born about the year 1560. After attending St. Leonard's College, St. Andrews, between 1573–74 and 1578, he seems to have selected the legal profession, and in 1580, when about twenty years of age, he was at Paris studying the civil law. He subsequently became private secretary and master of requests to Anne of Denmark, wife of James VI. On the occasion of the baptism of Prince Henry on 30th August, 1594, the preparation of the pageants exhibited "was by the king's majesty committed to the lord of Lindores and Mr. William Fowler;" and the description of these "rareshows and singular inventions" was published at the time. The sister of Fowler, Susannah, was married to Sir John Drummond, Knight, and gentleman usher of the black rod, and was mother of the celebrated poet Drummond of Hawthornden. On the title of some of his works Fowler styles himself P. of Hawick, thus indicating that he was parson or rector of Hawick. He is frequently styled Sir William Fowler, but there is no evidence that he was ever knighted. That Fowler was a man of very superior literary merit is evinced by his works, which are still preserved. The first of these is a collection of sonnets entitled *The Tarantula of Love;* the other is a translation from the Italian of the *Triumphs of Petrarch.* These two manuscripts were presented by his nephew, Drummond of Hawthornden, to the library of the university of Edinburgh in 1626, and it is understood both will shortly be published. Fowler was a great favorite at court. He prefixed a panegyrical sonnet to *The Furies*, a composition of James VI., while the king in return performed a similar office for his *Triumphs of Petrarch*, in a strain of versification which for vigor and fluency was vastly superior to his common style. Besides the above, two volumes of his manuscript notes, scrolls of poems, etc., are preserved among the Drummond MSS., in the library of the Society of Antiquaries of Scotland. Specimens of Fowler's verses were published in 1823 by Leyden in his *Scottish Descriptive Poems*, and are also to be found in other collections illustrating the poetry of the period.

---

[1] Like *Deer* (Danish *Dyr*, German *Thier*). *Beast*, too, with some men has almost attained as much specialization.

FOWNES, George (1815–1849), Ph.D., F.R.S., an eminent chemist, was born in London. He early showed an interest in scientific pursuits, and when seventeen or eighteen years of age joined with Dr. Henry Watts and Mr. Everett in establishing a philosophical class at the Western Literary Institution in Leicester Square. In 1837 he entered the laboratory of Everett, lecturer on chemistry at the Middlesex Hospital; and in 1839 he studied for some time under Professor Liebig at Giessen. He was lecturer on chemistry first at the Charing Cross and then at the Middlesex Hospital Medical School, as also at the school of the Pharmaceutical Society. In 1845 he was appointed director of the Birkbeck Chemical Laboratory in University College, London. He died of consumption, January 31, 1849. Besides his well-known and frequently re-edited *Manual of Chemistry*, and the Acton prize essay of the Royal Institution, entitled *Chemistry, as exemplifying the Wisdom and Beneficence of God*, Fownes wrote numerous scientific papers, among others the following:—

"On the Direct Formation of Cyanogen from its Elements," *Rep. Brit. Assoc.*, 1841, part ii. pp. 52, 53; "On the Preparation of Artificial Yeast," *Mem. Chem. Soc.*, i., 1841–43, pp. 100–103; "On the Preparation of Hippuric Acid," *Phil. Mag.*, xxi. 1842. pp. 382–384; "On the Food of Plants [prize essay], *Journ. Agric. Soc.*, iv., 1843, pp. 498–556; "On the Existence of Phosphoric Acid in Rocks of Igneous Origin," *Phil. Trans.*, 1844, pp. 53–56; "An Account of the Artificial Formation of a Vegeto-alkali" (Furfurol), and "On Benzoline," *ib.*, 1845, pp. 253–268; "On the Production of Furfurol," *Pharm. Journ.*, 1849, 113–116; "On the Equivalent or Combining Volumes of Solid Bodies," *ib.*, pp. 334–339.

FOX (*Vulpes*), a genus of digitigrade Carnivora, belonging to the *Canidæ* or dog family, but differing from the true dogs (*Canis*) in the greater elongation and sharpness of the muzzle, and in the greater length and bushiness of the tail. They likewise differ in the pupil of the eye being elliptical when contracted, and in the possession of a subcaudal gland, in which a fetid substance is secreted, the emission of which gives to foxes their peculiarly disagreeable odor. There are 24 recent species of foxes known, distributed over all the great continents except South America and Australia. Of these the Fennec foxes are exclusively African, and the bristle-tailed foxes North American. The Common Fox (*Vulpes vulgaris*), the pet of the hunting field and the pest of the farmyard, occurs throughout Europe, wherever it has not been exterminated by man. It is the Scottish *tod* and the French *renard*. It measures about two feet in length exclusive of the tail, which is about a foot long. Its fur is of a reddish-brown color above, and more or less white beneath; the back of its ears and the fore part of its limbs are black, and the tip of its bushy tail, or brush as it is called, is white. Its long, sharp muzzle, erect pointed ears, and sharp eye give it an appearance of sagacity and cunning which its real character fully justifies. The fox is undoubtedly the subtlest of British beasts of the field, its intellectual capacity having no doubt been enlarged by the peculiarly hard conditions under which alone it is permitted to exist in this country. It is regularly hunted by the fleet and keen-scented fox-hounds, urged on by mounted huntsmen, all of whom are not unfrequently baffled by the speed, cunning, and ingenuity of this wily creature. The fox is a solitary animal, inhabiting a burrow known as its earth, which it either excavates for itself, or, as more usually happens, obtains by previously ejecting the badger or the rabbit from its home. So averse, indeed, is the fox to dig for itself, that when foiled in its attempts to dispossess the badger, it has been known to take up its quarters with the latter, and in Germany it is readily induced to make its home in artificial burrows, constructed of stone and earth for the purpose of facilitating the operation of digging out the cubs. The fox also occurs in woods, and even in the open country without burrows, lying in its "cover" by day and stealing forth at night, when alone it can be said to see properly in search of its prey. Its food consists of rabbits, hares, poultry, and game-birds, although when these are not to be had it is fain to satisfy its hunger with rats, mice, and even insects—"the droppings of these creatures," says Bell, "being often composed almost entirely of the wing cases of beetles." The fox also visits the sea-shore, where it feeds on shell-fish and crustaceans; and on the Continent it is said to frequent the vineyards in order to gratify its taste for ripe grapes. Although the flesh of most birds forms its favorite food, it is a curious circumstance, noticed by Dr. Weissenborn, that even the severest hunger cannot compel it to eat the flesh of birds of prey, while there is good reason to believe that the fox enjoys, if it does not even prefer, "high" meat. The female produces her young in April—the period of gestation extending from 60 to 65 days. These are usually from 5 to 8 in number, and for them she shows the greatest solicitude, defending them with the utmost courage, and exhibiting a boldness altogether foreign to her character at other times. The cubs attain their full size in about 18 months, and the duration of life in the species, judging from individuals kept in confinement, probably extends to 13 or 14 years. The cubs, like those of most Carnivora, are exceedingly playful, and may often be seen amusing themselves, after the manner of young dogs, in pursuit of their own brushes. Their resemblance to the dog does not, however, extend much further, for, unlike it, they seem incapable of attachment to man. Although taken young and brought up with dogs, their attachment does not go beyond refraining from biting the hand that is accustomed to feed them. They remain timid and suspicious, and are always ready to snap at any one seeking to be familiar. This incapability of domestication, and the fact that the dog and fox have never been known to interbreed, would seem to prove that these animals are by no means so nearly related as was at one time supposed. Ample proof of the very considerable intellectual capacity of the fox is to be found in the stratagems to which it has recourse in securing its prey, but still more in the quickness with which it detects man's strategic efforts to outwit and capture it. "Its instinctive cunning," says Bell, "leads it soon to suspect the wiles of its enemies, and it will in a very short time ascertain the design of a trap or a gin, though concealed with the utmost care." Nothing can exceed the caution with which reynard approaches and examines the baited trap, or the *nonchalance* with which he approaches, enters, and rifles the snare in which some animal has been already caught, and which he evidently knows can do him no injury until reset. There are also several well-authenticated cases of the fox counterfeiting death in order to escape from its enemies. Attempts have been made to put a different interpretation on such instances, but examples of "feigning" have of late years been noticed in so many and such diverse animals,—among insects, reptiles, birds, and mammals,—that there seems no reason to doubt that the wily fox has recourse to a stratagem which, for want of a better term, may be described as counterfeiting death.

Closely allied to the common fox of Europe is the Red Fox (*Vulpes fulvus*) of eastern North America, regarded by many naturalists as only a variety of the common species—an opinion which receives some confirmation from the fact that hitherto no remains of the red fox have been found in the cave deposits of that continent, although remains of the gray fox are abundant. It may thus possibly be the descendant of individuals of the European species, introduced at a comparatively early period, and owing the differences that now distinguish it to the greatly altered conditions under which for centuries it has existed. It is altogether larger than the common fox of Europe, and the fur is longer and softer, the color more brilliant, and the muzzle less extended. According to Sir J. Richardson, it preys largely on the smaller animals of the rat family, and is very fond of fish. "The red fox," he says, "does not possess the wind of its English congener. It runs for about 100 yards with great swiftness, but its strength is exhausted in the first burst, and it is soon overtaken by a wolf or a mounted horseman." In Canada and the United States it is largely hunted for its valuable fur, about 60,000 skins of this species being annually imported into the London market. There are several well-known varieties of the red fox, as the cross fox and the black or silver fox. The latter is very scarce, and its fur is more valuable than any other found in North America. La Hontan states that in his time a skin of the silver fox was worth its weight in gold, and an unusually fine skin has been sold in the London market for £50. The fur is sometimes of a uniform black shining color, except at the tip of the tail, which is white; but more usually it has a hoary appearance from the admixture of white tipped hairs with those entirely black. This fox is exceedingly shy and difficult of approach, owing probably to the persistency with which it is hunted by the fur traders. About 1600 skins of the silver fox are annually imported into Britain. The Arctic fox (*Vulpes lagopus*) is an inhabitant of the boreal regions of Europe, Asia, and America. It is somewhat smaller than the

European fox, its ears being less pointed and the muzzle shorter. The soles of its feet are densely furred, resembling those of a hare, hence its specific name, *lagopus*. As with many Arctic animals the color of its fur changes with the season, being in most cases of a pure white color in winter, with the exception of a few black hairs at the extremity of the tail. Towards the end of April, however, when the Arctic snows begin to disappear, the long white fur gives place to shorter hair of a dark brown or sooty color. Occasionally a dark-colored fox may be seen in winter, and a white one in summer, and in Iceland, according to Professor Newton, the winter coat differs very slightly in color from that of summer, probably owing to the comparatively mild character of the Icelandic winter. The Arctic fox has little of the proverbial cunning of its kind, having been seen to walk unsuspiciously into the trap which had been baited in its presence. It is an exceedingly cleanly animal, and the fetid odor characteristic of the entire genus is almost absent in this species. It differs also from the common fox in being gregarious, living, according to Richardson, in little villages consisting of 20 or 30 burrows placed near each other. The Arctic foxes seek their food, which consists of lemmings, birds, eggs, and carrion, at night, and their first impulse, says Captain Lyon, on securing it is to hide it, even though suffering severely from hunger. It was suggested some years ago by Professor Newton that this species supported itself during winter on a store of provisions laid up during summer, and Captain Feilden was able during the recent polar expedition (1875) to confirm this. When in Grinnell Land he and his companions came upon Arctic foxes, and were greatly surprised on discovering numerous deposits of dead lemmings. "In one nook," says Captain Feilden, "under a rock we pulled out over 50; we disturbed numerous *caches* of 20 and 30, and the ground was honeycombed with holes, each of which contained several bodies of these little animals, a small quantity of earth being placed over them" (*A Voyage to the Polar Sea*, by Captain Sir G. Nares, 1878). Nearly 10,000 skins of the Arctic fox, chiefly in winter fur, are annually brought into Britain.

Foxes are found fossil in caverns in many parts of Europe, and extinct species occur in the Tertiary deposits of both hemispheres. (J. G. I.)

FOX, Charles James (1749–1806), born on the 24th of January, 1749, at 9 Conduit Street, in the city of Westminster, was the third son of Henry Fox, first Lord Holland. His mother was the eldest daughter of the second duke of Richmond. As his great-great-grandmother was duchess of Portsmouth, he had in his veins the blood of Charles II. of England and Henry IV. of France. His paternal grandfather, Sir Stephen Fox, was born shortly after Charles I. ascended the throne, and died shortly after the accession of George I. The public services of this member of the Fox family have received less notice than they deserve. He was a yeoman's son who, having been taught to read, write, and cipher, was considered capable of rising in the world. When a youth he first obtained a situation in the household of the earl of Northumberland; then he entered the service of Lord Percy, the earl's brother, and he was present with the royalist army at the battle of Worcester as Lord Percy's deputy at the ordnance board. Accompanying Charles II. in his flight to the Continent, he served him in a menial capacity during his exile, till he was promoted to be keeper of the privy purse. He was employed as intermediary between the king and General Monk. Honors and emolument were his reward after the Restoration; he was knighted, and appointed to the lucrative offices of clerk of the green cloth and paymaster of the forces. He entered the House of Commons, first as member for Salisbury, and secondly for Westminster. He succeeded the earl of Rochester as a commissioner of the treasury, filling that office for 23 years and during three reigns. At the mature age of seventy-seven he married for the second time; four children were the issue of this marriage. He died in 1716 at the age of eighty-nine, and left a large fortune. It is his distinction to have founded Chelsea hospital, and to have contributed £13,000 in aid of this laudable public work. Though his place as a statesman is in the second or even the third rank, yet he was a useful man in his generation, and a public servant who creditably discharged all the duties with which he was entrusted. Unlike other statesmen of his day, he grew rich in the service of the nation without being suspected of corruption, and without forfeiting the esteem of his contemporaries. Sir Stephen Fox's second son by his second marriage was named Henry. Inheriting a large share of the riches which his father had accumulated, he squandered it soon after attaining his majority. Henry Fox went to the Continent to escape from his creditors. There he made the acquaintance of a countrywoman of fortune, who became his patroness and was so lavish with her purse that, after several years' absence, he was in a position to return home and to enter parliament as member for Hindon. He became the favorite pupil and devoted supporter of Sir Robert Walpole, achieving unequalled and unenviable proficiency in the worst political arts of his master and model. As a speaker he was fluent and self-possessed, imperturbable under attack, audacious in exposition or retort, and able to hold his own against Pitt himself. Thus he made himself a power in the House of Commons, and an indispensable member of several administrations. He heaped up riches when acting as paymaster of the forces during the war which Pitt conducted with extraordinary vigor, and in which the nation was intoxicated with glory. He served under the earl of Bute in order that he might exercise his skill in cajolery and corruption to induce the House of Commons to approve of the treaty of Paris; as a recompense, he was raised to the House of Lords with the title of Baron Holland. He strove, but in vain, to obtain promotion to the dignity of an earl, a dignity upon which he had set his heart, and he died a sorely disappointed man, with a reputation for cunning and unscrupulousness which cannot easily be matched, and with an unpopularity which justifies the conclusion that he was the most thoroughly hated statesman of his day. Henry Fox's affection for his son Charles James verged on idolatry. The boy was both precocious and engaging. Whatever he chose to learn, he acquired with ease, and he displayed more than a boy's good sense in correcting his faults. Once he overheard his mother, with whom he was no favorite, remark to his father, "Charles is dreadfully passionate; what shall we do with him?" and the reply, "Oh, never mind; he is a very sensible little fellow, and he will learn to cure himself." Thereupon he resolved to repress his angry passions, and he succeeded in rendering himself a pattern for gentle bearing and command of temper. He went to Eton when he was nine, having spent the preceding year, at his own request, in the school kept at Wandsworth by Pampelonne a French refugee. The boy's health was delicate, and this caused his father much anxiety. He was not diligent in learning, nor was his tendency towards indolence at school counteracted by the discipline to which he was subjected. The Rev. Dr. Francis, his tutor, sent to his father accounts more flattering than just of his son's progress and attention, and better fitted to gratify parental fondness than set forth the truth. He often went home in order to accompany his parents to some notable spectacle, chief among them being the coronation of George III., where he met with a slight accident, which, being reported in the newspapers, caused his father to write, "The article [in the newspapers] of Charles's mishap has brought several messages. The boy is a great deal better beloved than his father is." When fourteen he left school for four months, which he spent with his parents at Spa and Paris. His father taught him to game at Spa, giving him several gold pieces wherewith to try his luck, as the saying is, every evening. Hence he early became addicted to the vice which was for some years his besetting sin, and for which he could urge no other excuse, when taunted with it later by Lord Hillsborough in the House of Commons, than that it was a vice "countenanced by the fashion of the times, a vice to which some of the greatest characters had given way in the early part of their lives, and a vice which carried with it its own punishment, and entailed a curse upon those who were addicted to it." He returned to Eton thinking himself a thorough young man of the world; but his dandified airs only excited the ridicule of his comrades, and Dr. Barnard, the head master, by flogging him for misconduct, made him feel keenly that he was still a mere schoolboy. More instructive and advantageous than trips to the Continent and visits to Continental gaming houses were the visits which he made to the Houses of Parliament, in company with his father, to hear important debates. He was in the gallery of the House of Commons when Lord North moved "that the paper entitled the *North Briton* is a false, scandalous, and seditious libel." His father impressed upon him that John Wilkes was a bad man, and that the earl of Bute was a sagacious minister; these opinions were embodied by him in some French verses, which injudicious admirers have reproduced to show his want of mastery over the French language, and the absurdity of his boyish political sentiments. Leaving Eton in 1764, Fox went to Oxford, where he entered Hertford College. In a letter to his friend Mr. Macartney he professed a great liking for Oxford and fondness for mathematics, adding, in another letter, that he believed mathematics were useful, and was sure they were entertaining, this being enough, in his opinion, to recommend them. The same letter contained his judgment on a newly published poem, which is far less paradoxical and more creditable to his discernment than the foregoing statement concerning mathematics. The poem was the *Traveller*, which the youthful critic pronounced, with perfect truth, "to have a good deal of merit." A trip to Paris and a stay there of two months interrupted Fox's university career. Dr. Newcome, the head of his college, readily sanctioned this holiday, making the complimentary remark that such application as his required "some intermission, and you are the only person with whom I have ever had connection to whom I could say this. . . . You need not interrupt your amusements by severe studies; for it is wholly unnecessary to make a step onward without you, and therefore we shall stop until we have the pleasure of your company." This visit to the capital of France was no more serviceable to him, in a moral sense, than his previous one. His father encouraged him to indulge himself without stint in pleasures to which young men are only too prone, and, what is still more blameworthy, jested at the scruples of a son who had no strong liking for vicious courses. On his return to Oxford he worked hard at his studies, spending the greater part of a vacation in systematic reading along with his friend Dickson, who was afterwards bishop of Down. Their leisure was devoted to perusing the works of the early English dramatists, all of which they read. Taking his degree in 1766, he left Oxford and spent the succeeding two years in Continental travel, traversing France and Italy, either in company with his parents, or else with his friends Lord Carlisle, Lord Fitzwilliam, and Mr. Uvedale Price. Along with Mr. Price he visited Voltaire at Ferney, where he was heartily welcomed by the great Frenchman for his father's sake, and was advised to read Voltaire's published works in order that he might emancipate himself from religious prejudices and increase his stock of ideas. He became a proficient in speaking the French tongue, and he practised himself in writing it by penning poetical epistles in French to his friend Fitzpatrick. He also mastered Italian, which he admired beyond measure, saying that there was "more good poetry in Italian than in all other languages that I understand put together." He was then passionately fond of amateur acting and of wearing fine clothes. In after days his friends could scarcely credit the assurance of the friends of his youth when the latter stated that Fox, who had become a sloven in dress, was once a "macaroni," having made a journey from Paris to Lyons in order to buy waistcoats, and was in the habit of walking about with a little French hat on his head and red-heeled shoes on his feet. As difficult was it for some among them to realize that Fox, the leader of the Whigs, and even further advanced in Liberal opinions than the majority of his party, had been such a Tory at the outset of his parliamentary career as to write to George Selwyn in the following terms: "I am reading Clarendon, but scarcely get on faster than you did with your Charles V. I think the style bad, and that he has a great deal of the old woman in his way of thinking, but hate the opposite party so much that it gives one a kind of partiality for him." Hating the opposite party so thoroughly, it is not surprising that he should have been inimical to the first administration of the marquis of Rockingham, an administration that repealed the Stamp Act which George Grenville had designed to raise a revenue in the American Colonies, an administration which was far too liberal in tendency and independent in character to suit the narrow and personal views of George III., and that he should have written to Sir George Macartney, "everybody laughs at its members, holds them cheap, but, according to the fashionable phrase, doing justice to their good *intentions*." In 1768, when still under age, Fox was returned for Midhurst, then a pocket borough. His father having made the arrangements necessary for his election had thereby provided a supporter of the ministry of the day which the earl of Chatham had formed, and in which the duke of Grafton was first lord of the treasury. Fox's maiden speech in the House of Commons was delivered in defence of the ministry and in opposition to seating John Wilkes as member for Middlesex. He at once made his mark as a parliamentary speaker, recalling to some members the best traits of Charles Townshend and the elder Pitt. His father, delighted at the success achieved by his favorite son, communicated his satisfaction to his acquaintances, and wrote to one of them that he had been told Charles had spoken extremely well:—"It was all off-hand, all argumentative, in reply to Mr. Burke and Mr. Wedderburn, and excessively well indeed. I hear it spoken of by everybody as a most extraordinary thing, and I am, you see, not a little pleased with it." Fox had his reward by being appointed a lord of the admiralty immediately after attaining his majority, and when Lord North had succeeded the duke of Grafton as prime minister. Two years afterwards he resigned, on account of a misunderstanding with his chief and a determination to oppose the Royal Marriage Bill, which the ministry introduced out of deference to George III., and about which the king wrote to Lord North:—"I do expect every nerve to be strained to carry the Bill through both Houses with a becoming firmness, for it is not a question that immediately relates to administration, but personally to myself; therefore I have a right to expect a hearty support from every one in my service, and shall remember defaulters." Fox not only opposed this bill, which was framed to discourage members of the royal family from marrying, and to throw artificial obstacles in their way should they desire to make love matches, but he also introduced a bill to amend Lord Hardwicke's Act, "For the better preventing of Clandestine Marriages," which his father had virulently opposed. This conduct, which gave great offence to George III., was the origin of that implacable enmity to his great subject which ever after prevailed in the royal breast, to the detriment alike of the throne and the country. In introducing his bill Fox is said by Horace Walpole to have spoken "with ease, grace, and clearness;" he effectively answered Edmund Burke and Lord North who opposed it, ridiculing the arguments of the former and confuting those of the latter, "with a shrewdness that, from its multiplicity of reasons, as much exceeded his father in embracing all the arguments of his antagonists as he did in his manner and delivery." This was doubly agreeable to his father, who had formed a clandestine marriage, and who thought such an Act as Lord Hardwicke's a slur upon himself. The attempt of his son failed, though he had the triumph of beating the ministry by a majority of one on a motion for leave to introduce the bill. After being a year out of office, he became reconciled to Lord North, and re-entered the administration as a junior lord of the treasury. But he soon reasserted his independence, differing from Lord North on a question of procedure, and causing the defeat of the ministry in the House of Commons by pressing an unwelcome motion to a division. The king was incensed at what he styled Charles Fox's presumption, adding, in a letter to the premier, "Indeed, that young man has so thoroughly cast off every principle of common honor and honesty that he must become as contemptible as he is odious; and I hope you will let him know you are not insensible of his conduct towards you." Lord North, acting in conformity with the king's suggestion, wrote as follows to Fox:—"Sir, his Majesty has thought proper to order a new commission of the treasury to be made out, in which I do not see your name." Thus ended the first stage of Fox's political career. A year later he avowed in the House of Commons that "the greatest folly of his life was in having supported Lord North." He was chargeable with follies of another kind. Among the young men of the day he was conspicuous for staking money at play and making bets on horse races. Sometimes he won bets made at Newmarket, but he almost invariably lost larger sums in a gaming club at Almack's, where the stakes were £50, and where as much as £10,000 was on the table at a time. Lord Holland advanced £40,000 to pay his debts, but this did not suffice, and he became the dupe of a Mrs. Grieve, who, on the pretext of introducing him to a Miss Phipps, a West Indian heiress, obtained money from him. His reputation stood so low in public estimation that, according to Horace Walpole, it was commonly supposed he had been dismissed by Lord North for robbing the treasury. In 1774 Fox began that opposition to the ill-advised and ill-fated measures of Lord North which gave him a place among the greatest of orators and the most prescient of statesmen. He lost both his parents in that year, and his brother Stephen, second Lord Holland, soon followed them to the grave, leaving behind him the boy whom Fox treated with almost paternal fondness and care, whose memory as third Lord Holland is held in kindly remembrance, and who, with characteristic modesty, considered it his chief glory to have been the nephew of Fox and friend of Grey. Soon after Fox entered the ranks of the Opposition he became its acknowledged chief. This rapid advancement was largely due to the lessons in practical politics taught him by Edmund Burke, whose acquaintance he had made in early life. The story of his career from 1774, when he left Lord North's administration, to 1782, when Lord North resigned and when he became secretary of state in the second Rockingham administration, is associated with the unsparing and brilliant opposition of the Whig party to the war which ended with the ratification of the independence of the Thirteen United Colonies of America. An important episode during that period was his election as member for the city of Westminster. On the 2d of February, 1780, a meeting in favor of parliamentary reform was held in Westminster Hall, at which such leading members of the Whig party were present as the duke of Portland, Earl Temple, John Wilkes, General Burgoyne, Alderman Sawbridge, Edmund Burke, and over which Fox presided. He delivered a stirring speech in favor of a redress of grievances, and in particular of a reform in the representation of the people. After it had been resolved that a petition to that effect should be presented to parliament, it was proposed and carried by acclamation that Fox, "the Man of the People," should become a candidate to represent Westminster in the House of Commons, and before the year closed he was a member for the constituency which he represented till the end of his life. A little more than a century had then elapsed since Sir Stephen Fox, his grandfather, had been first returned for the city of Westminster. George III. encouraged the opposition to the election of the "Man of the People," of whom he wrote that "Fox never had any principle, and can therefore act as his interest may guide him." Eight thousand pounds were contributed out of the civil list to promote the success of Lord Lincoln, the favorite of the court, yet neither corrupt expenditure nor royal disapproval sufficed to hinder the triumph of Fox. As secretary of state in the ministry of the Marquis of Rockingham, and leader of the House of Commons, Fox displayed great business aptitude and capacity for conciliation. A short time before he became minister, Horace Walpole wrote to Sir Horace Mann:—"Mr. Fox is the first figure in all the places I have mentioned,—the hero in parliament, at the gaming-table, at Newmarket." After he became minister, the same writer informed his correspondent—"Mr. Fox already shines as greatly in place as he did in opposition, though infinitely more difficult a task. He is now as indefatigable as he was idle. He has perfect temper, and not only good humor but good nature, and, which is the first quality of a prime minister in a free country, has more common sense than any man, with amazing parts that are neither ostentatious nor affected." His experience of high office was very short. Lord Rockingham became premier on the 27th of March, 1782; he died on the first of the following July, and Fox resigned immediately afterwards. He had finally resolved to do so before the death of his chief, having been outvoted in the cabinet on the question of unconditionally acknowledging the independence of the United Colonies. His brother secretary of state, the earl of Shelburne, and other colleagues thought that the concession of independence should be made one of the conditions of peace. Fox regarded Shelburne with undisguised aversion. When the administration was formed, he fancied that Shelburne was disposed to imitate Lord North and to pay undue deference to George III., and he told him that it appeared "the administration was to consist of two parts, one belonging to the king, the other to the public." Four weeks after being in office Fox wrote to his friend Fitzpatrick:—"Shelburne shows himself more and more every day, is ridiculously jealous of my encroaching on his department, and wishes very much to encroach upon mine." Shelburne, in turn, suspected Fox of designs to monopolize power, and to have his own way in all things. This unfortunate antagonism between two men of remarkable ability caused a split in the Whig party, and enabled the king to succeed in his policy of entrusting power only to ministers who were subservient to his will. Succeeding Lord Rockingham as premier, Shelburne held office till the 24th February, 1783. The coalition ministry, in which the duke of Portland was premier, and Lord North and Fox were secretaries of state, took the place of that over which Shelburne had presided. It was with extreme and undisguised reluctance that the king permitted this administration to be formed. When he found it hopeless to struggle against the inevitable result, he communicated his real feelings on the subject to those politicians who prided themselves upon being his friends. In conversation with Mr. Wyndham Grenville, he poured out his indignation "upon Fox, whom he loaded with every expression of abhorrence; upon the duke of Portland, against whom he was little less violent; upon Lord North, to whose conduct he imputed all the disasters of the country; upon American independence, which seemed to have been a most bitter pill indeed." His early detestation of Fox had now been intensified, owing to the unnatural behavior of his eldest son, which he erroneously attributed to the teaching of the great Whig statesman. The king even consulted Lord Chancellor Thurlow and Lord Ashburton as to "what redress he could have against a man who alienated from him the affections of his son," and it is said that Thurlow told him "he would have no peace till his son and Fox were secured in the Tower." One of the first acts of the coalition was to arrange about the establishment and income of the Prince of Wales. The king was shocked at the proposition which the ministry laid before him, considering the sum which had been agreed upon as a fitting one for the prince to receive utterly extravagant; and he alleged that his advisers were ready to sacrifice the public interests to gratify an "ill-advised young man." In consequence of the king's disapproval of the scheme, his eldest son had to content himself with an allowance which was wholly inadequate; hence he had to make repeated applications to parliament to pay his debts. While the coalition ministry held office the definitive treaties of peace were signed between Great Britain and France, Spain, and the United States of America, and thus the war which a ministry after George III.'s own heart had provoked and carried on with amazing incompetence ceased to impoverish and humiliate the nation. But the chief act of the administration and the cause of its downfall was the introduction of a bill for the just and efficient government of British India. Though Burke had the principal share in planning the measure, yet Fox, having made himself thoroughly master of the questions at issue, expounded the scheme in the House of Commons with great lucidity and impressiveness. The opposition to it was vehement and disingenuous; the measure was falsely described as having been solely designed in order to confiscate the property of the East India Company and establish the supremacy of the Whig party. William Pitt, who was then unsparing and unfair in his criticism, afterwards did practical justice to the wisdom of Fox and his colleagues by bringing a measure into parliament resembling that of the coalition ministry in many essential particulars. Fox's prediction was thus verified, for the day arrived when his statesmanlike and much maligned bill was "regarded in its true light as a strong, but as a necessary and a just measure." But the king had determined that the bill which Fox had safely piloted through the House of Commons should never pass into law; several persons calling themselves his friends aided him in accomplishing his object, and the ministry, after being defeated by a small majority in the House of Lords, was summarily and contemptuously dismissed. Twenty-two years elapsed before Fox returned to office.

During three months after his dismissal, Fox endeavored to counteract the power of the sovereign to dissolve parliament; but he was baffled by the boldness and patience of William Pitt, the young prime minister. Then followed a more trying discomfiture when the country pronounced in favor of his rival at the general election of 1784. Even the Nonconformists, who had no warmer advocate than Fox, and whose only hope for the redress of intolerable grievances consisted in the Whig party being in office, turned against their true friends, rallying to the shout of "Pitt and the constitution," instead of aiding by voice and vote the cause of "Fox and free government." They deserted him at a critical juncture. Nevertheless he continued to plead for them with his whole heart and soul, and merely remarked, "on recollection of what had been their conduct upon that occasion [the coalition], the House would at least do him the justice to say that, in supporting them that day, he was not influenced by any very obvious motives of private partiality or attachment. Yet he was determined to let them know that, though they could upon some occasions lose sight of their principles of liberty, he would not upon any occasion lose sight of his principles of toleration." It was not enough for the king and the young and haughty premier that the Whig party should be defeated in the country; they were resolved to exclude Fox from parliament, and in any case to prevent his re-election for Westminster. Admiral Lord Hood, Sir Cecil Wray, and Fox were the candidates for the two seats. The court and the ministry were bent upon the first two being chosen. What the king styled "gold pills" were lavished on the occasion. Moreover, 280 of the Guards were sent to vote as householders, a thing which Horace Walpole said his father "in the most quiet season would not have dared to do." The character of the struggle recalled an envenomed contest 89 years previously, when the Jacobites strove with all their might to hinder the re-election of Sir Stephen Fox, a declared supporter of the Revolution settlement. In 1784, as in 1695, the party of freedom and constitutional government carried the day in Westminster, and Fox was returned by a majority of 236. But the partisans of divine right in 1695 never dreamed of retrieving their defeat in the manner which found favor in the eyes of George III. and his advisers in 1784. A scrutiny was demanded, in order that Fox might not take his seat. Happily, this pettifogging manœuvre was thwarted by the action of attached friends, who procured his election for the Kirkwall burghs. The validity of this election was challenged, but without result, and Fox was able to make that impassioned and masterly protest in the House of Commons against the shameful treatment to which he had been subjected, which is known as his speech on the Westminster scrutiny, and which ranks among the best speeches ever delivered in parliament. The scrutiny went on for a year, till even Pitt's docile majority resented the further continuance of the unconstitutional farce, and voted that it should end. In consequence of this Fox took his seat as member for Westminster, brought an action against the high bailiff, who had conducted himself in the affair as a tool of the ministry, and recovered £2000 damages, which he distributed among the Westminster charities. The remainder of Fox's parliamentary career is more remarkable for eloquent speeches than for stirring personal incident. His criticism of Pitt's measures was always shrewd and vigorous, though not invariably just. He blundered most seriously in denouncing the commercial treaty with France, a scheme of far-seeing policy and admirable patriotism. When this subject was debated he gave utterance to a phrase which, like the utterances of many other notable men, has been repeated to his discredit by persons who, purposely or inadvertently, dissociate it from the context, and withhold the qualifying clauses. Having said that "France was the natural political enemy of Great Britain," he was reproached for calling the French the natural enemies of the English. What he meant to convey was, not that enmity necessarily existed between the English and the French, but that the policy of France, as directed by the house of Bourbon, was irreconcilably opposed to the interests of England, a proposition which was really incontrovertible. His liking for the French people was extreme, and this was openly displayed so soon as they had emancipated themselves from a rule which they detested, and which rendered them the disturbers of the world. Then he avowed his conviction that the new form of government in France "would render her a better neighbor, and less disposed to hostility, than when she was subject to the cabal and intrigues of ambitious and interested statesmen." Again, it is forgotten or concealed by those persons who have censured Fox on account of his objection to this treaty, "that he earnestly recommended, instead of the present treaty, a more intimate connection with the United States of America, such an intercourse for Britain that could be devised, and was entirely consistent with her true political interests, and such an intercourse he had the best reason for believing America was both willing and eager to enter into upon fair and equitable terms." Indeed, Washington was anxious to conclude a commercial treaty with Great Britain, but Pitt discountenanced the notion. It was wise in Fox to urge this as most desirable, yet he would have shown still greater wisdom in aiding to the utmost the project for increasing commercial intercourse with France also. On other questions he displayed genuine liberality of sentiment and the highest statesmanship. He declared emphatically against the slave trade at a time when Pitt took credit for delivering no opinion in favor or in disapproval of the traffic in negroes. He repeatedly moved for the repeal of the Test and Corporation Acts, and he advocated a thorough-going scheme of parliamentary reform. He was one of the managers when Warren Hastings was impeached by the Commons of England of high crimes and misdemeanors; he had mastered the subject, spoke on it in a more businesslike, though less rhetorical and sensational style than Burke and Sheridan, while his judgment was accepted as conclusive when his brother managers differed in opinion. His health being impaired, he went to the Continent in 1788 for relaxation and change, revisiting Switzerland and Italy. He spent a short time with Gibbon at Lausanne. The luminous historian has chronicled the pleasure which he reaped from this visit of the illustrious statesman; how they conversed without ceasing from morning to night, adding, "we had little politics; though Fox gave me in a few words such a character of Pitt as one great man should give of another his rival; much of books, from my own, on which he flattered me very pleasantly, to Homer and the *Arabian Nights;* much about the country, my garden (which he understands far better than I do); and upon the whole I think he envies me, and would do so were he a minister." At Bologna, in November, 1788, he received an urgent summons to return home, owing to the meeting of parliament on the 20th of that month having been rendered necessary on account of the king's sudden and serious illness. While journeying to England he heard a report that George III. was dead, being the truth that the monarch had been suddenly bereft of his reason. Travelling with all the speed possible in those days, Fox arrived in London on the ninth day after leaving Bologna. He had gone abroad for his health; the journey back nearly killed him. Wraxall says that Fox's appearance when he entered the House of Commons on the 4th of December, "excited a great and general sensation. I never saw him, either previously or subsequently, exhibit so broken and shattered an aspect. His body seemed to be emaciated, his countenance sallow and sickly, his eyes swollen; while his stockings hung upon his legs, and he rather dragged himself along, than walked up the floor to take his seat." Both Pitt and he made mistakes during the debates on the regency, both thinking less of what was best to be done in the circumstances than about the most suitable course to pursue for the purpose of securing the supremacy of their respective parties. Pitt dreaded the loss of office should the Prince of Wales become regent, with full power to conduct the government; Fox was confident that, if the prince exercised the royal prerogatives, a Whig administration would be constituted. The unexpected recovery of the king put an end alike to hopes of promotion and fears of dismissal; but the record of blunders which cannot be excused, and of aspirations which were wanting in patriotism, remained to sully the fame of Tory and Whig leaders. The divergence of opinion between the Whig and Tory parties, and among the members of the Whig party, grew wider, and more deplorable when the French Revolution agitated Europe and terrified many Englishmen. An outcry was raised against French principles, and against those persons who held that the surest way to avert danger to England was to remove all reasonable grounds for popular dissatisfaction. The mob of Birmingham, frenzied with panic and overflowing in loyalty, pillaged the houses of Dr. Priestley and other Nonconformists, in order to testify attachment to "church and king," a cry which Dr. Parr characterized as the toast of Jacobites and the yell of incendiaries, meaning, "a church without the gospel, and a king above the laws." Handbills circulated in the neighborhood where Fox dwelt contained the threat, "Destruction to Fox and his Jacobite crew." He expressed in the House of Commons his foreboding that his own dwelling might be dealt with in the same way as Dr. Priestley's, yet he persevered in upholding freedom of speech and of the press when the ministry carried the Traitorous Correspondence Act, the Seditious Practices Act, and the suspension of the Habeas Corpus Act. He too suffered for his attachment to liberal principles.

For proposing as a toast at the Whig club, "the sovereignty of the people of Great Britain," his name was expunged by the king from the list of privy councillors, at the special suggestion of Pitt. The duke of Norfolk had previously been subjected to the like indignity for having proposed on Fox's birthday the toast:—"Our sovereign's health; the majesty of the people." Finding it hopeless to struggle against the ministerial majority, which had been swelled by defections from the ranks of his own party and friends, he discontinued attending parliament in 1797, and spent his time at St. Anne's Hill in literary study and in writing a history of England from the reign of James II. The debts which had long embarrassed him were discharged by private friends in 1793, who settled an annuity of £3000 upon him. From that date he never touched a card. In 1795 he married Mrs. Armitstead, a lady with whom he had lived for some time. During this period he watched over the training of his nephew, the third Lord Holland, and prepared him for playing a useful part on the political stage. Immediately after the peace of Amiens he visited Paris, chiefly in order to examine the archives in the French foreign office for historical purposes. He visited Lafayette, and was cordially welcomed by the republican patriot, planting, in remembrance of his visit, the ivy which now mantles the turrets of the gateway at Lagrange. In common with other distinguished visitors to Paris, he was presented to Bonaparte. The war recommencing soon after his return home, he resumed his advocacy of peace; indeed, as the poet has truly said of this stage in his career, "peace, when he spoke, was ever on his tongue." Another feature of it was a complete understanding with the marquis of Lansdowne, formerly earl of Shelburne, on questions of foreign policy, the two acting in concert when any such matter was under debate in either House of Parliament.

Pitt died in January, 1806. The ministry of "All the Talents" was then formed, with Lord Grenville as first lord of the Treasury and Fox as secretary of state, despite the aversion and resistance of George III. Though loving peace as much as ever, he was yet ready to resist the inordinate pretensions of Bonaparte, and he declared war against Prussia when that power, acting as the vassal of the French conqueror and at his suggestion, annexed Hanover. Fox's last appearance in the House of Commons was on the 10th of June, 1806. Feeble in health, he appeared there at the risk of his life; but he could not forbear making a special effort in order to move resolutions preparatory to introducing a bill for the suppression of the slave trade. The resolutions were carried by large majorities in both Houses. The bill giving effect to them became law the following year. In this, his farewell speech, he said, "So fully am I impressed with the vast importance and necessity of attaining what will be the object of my motion this night, that if, during the almost forty years that I have had the honor of a seat in parliament, I had been so fortunate as to accomplish that, and that only, I should think I had done enough, and could retire from public life with comfort, and the conscious satisfaction that I had done my duty." On the 13th of the following September, he died, at the age of fifty-eight, of a schirrhous affection of the liver. The room in which he drew his last breath is in the duke of Devonshire's villa at Chiswick, and is the one wherein, at a later day, Canning died also. By Fox's death the country lost a statesman, who, despite his failings, is one of the finest and most fascinating figures in modern history,—a man who, in the phrase which Burke uttered six years after the friendship between them had ended, was "a man made to be loved," and of whom even George III., his single open and bitter enemy, said to Lord Sidmouth, "little did I think that I should ever live to regret Mr. Fox's death," and to his daughter Princess Mary, "I never thought I should have regretted the death of Mr. Fox as much as I do." Lamented by an unappreciative sovereign and by all discerning men, the mortal remains of the incomparable Whig statesman were carried in public funeral to Westminster Abbey, and laid alongside those of his brilliant and triumphant rival William Pitt.

It is not easy to determine the exact place which Fox would have held among English statesmen, if he had been allowed a suitable opportunity for the exercise and display of his talents. His name is associated with one great measure of practical legislation, the Act for amending the law of libel. Peace with the United States, the better government of India, the abolition of the slave trade, were some grand results of his untiring efforts and commanding advocacy. Scarcely any of the measures of reform carried into effect after his death had not been sanctioned and supported by him. Yet he performed but a small part of what he desired to accomplish. His fate had a close similarity to that of the earl of Shelburne, for whom, till a late period in his career, he felt a repugnance which was none the less unfortunate because it was reciprocated. Lord Shelburne, in common with Fox, was far in advance of his age. He neither dreaded the people nor overestimated their capacity. But he never had the chance of giving full effect to his convictions, and his best traits remained in obscurity till a descendant, with ample knowledge and admirable taste, has made them clear to the public of our day. Like Shelburne, the Whig commoner has been the victim of popular misunderstanding. His addiction to pleasure was considered by many contemporaries to be a fatal blot on his character. They argued in his case as Junius did in that of the duke of Grafton, who was denounced as an incompetent statesman because he appeared in public with Nancy Parsons, and was supposed to prefer the attractions of Newmarket to the sober business of cabinet councils. That the duke of Grafton was a man of exceptional capacity is now indisputable. Notwithstanding his liking for gaming and horse-racing, Fox was a thorough man of business, and a statesman for whom no work was too severe and no problem too difficult. The obstacles which Fox could not overcome, and which proved equal stumbling-blocks in Shelburne's path, were the dislike and distrust of George III. Yet, intensely as the king detested what he considered the Jesuitism of Shelburne, his feeling of antipathy to Fox was still more extreme and indefensible. This was due to aversion to his father, to the independence displayed by Fox when a member of Lord North's administration, and to the supposition that the undutiful behavior of his worthless eldest son was the result of Fox's direct influence and prompting. Charles Butler notes in his interesting miscellanies—"Cardinal de Retz said to a person who taunted him with the superiority of Cardinal Mazarin, 'Give me the king but for one day, and you'll see who has the real superiority.' Mr. Fox never had the king with him, even for one hour." When he was secretary of state in the coalition ministry, the king in his demeanor to him was "civil, but no more." The reason of this is obvious to all those persons who have studied George III.'s character. Not deficient in shrewdness, and abounding in the cunning which is the characteristic of men conscious and ashamed of their weakness of intellect, that monarch liked to have advisers who were not too strongly in contrast to himself, or else who would veil their capacity in their intercourse with him. A mere simpleton was as distasteful to him as a towering genius. Pitt, who liked to surround himself with dummies, had chosen Lord Hawkesbury to conduct foreign affairs. His incompetency being too conspicuous, the king told George Rose with gusto that, though the foreign ministers differed on many points, they were unanimous in their contempt and dislike for Lord Hawkesbury, and that "his lordship always approached him with a vacant grin, and had hardly ever anything business-like to say to him." In the presence of men of strong individuality and of great intellect, such as Chatham, Shelburne, and Fox, the king felt ill at ease, being conscious that his nominal servants were his real superiors. William Pitt pleased him, because Pitt, though a man of supreme talent and haughty to his equals and inferiors, was supple in the presence of his sovereign, and ready to defer to the sovereign's desires, to flatter his prejudices. Instead of impressing him with the opinion of the public on a given question, he professed anxiety to learn what his own view was in order to give effect to it. Once only did Pitt insist upon having his own way; failing, he resigned. But he returned to power on the clear understanding that he would not press the measure of justice to the Roman Catholics which he previously held to be necessary, and to which the king was sternly opposed. If George III. had deemed it possible that Fox would have been as submissive and considerate as Pitt, he would never have told George Rose that "he had taken a positive determination not to admit Mr. Fox into his councils, even at the hazard of a civil war," nor would he have written to Addington that "Mr. Fox is excluded by the express command of the king to Mr. Pitt." The wonder is that, despite the hindrances which were thrown in Fox's path, and the slight occasion which he had of proving in office how well fitted he was to discharge the most onerous tasks, he should yet have proved that no statesman of his age was better qualified for conducting the government of England. What Gibbon said of him during the war with the American colonies is applicable to his entire political career; he exhibited in the conduct of a party capacity for governing an empire.

It is unquestionable, that as a parliamentary orator, Fox has no superiors. Yet, notwithstanding many volumes contain his speeches, there is an insuperable difficulty in setting forth the secret of his oratorical greatness. One speech only is there printed as it was delivered, the single speech which he wrote out beforehand, being a eulogium on the deceased duke of Bedford. Another, that on the Westminster scrutiny, is said to have been reported with the accuracy which is now the rule. The records of Warren Hastings's trial comprise verbatim reports of the speeches which he delivered before the House of Lords. But no such evidence suffices to explain the extraordinary effects which his spoken words produced; hence, it is necessary to rely upon the testimony of contemporaries, and to accept their decision as conclusive. Pitt styled him a magician who laid a spell upon his hearers so long as words issued from his lips. A noble lord, thinking to curry favor with the premier, abused one of Fox's speeches, and received the generous reply from Pitt: "Don't disparage it; nobody could have made it but himself." Rogers has recorded that never did he "hear anything equal to Fox's *speeches in reply;* they were wonderful. Burke did not do himself justice as a speaker; his manner was hurried, and he always seemed to be in a passion. Pitt's voice sounded as if he had worsted in his mouth." Charles Butler said that Fox had a captivating earnestness of tone and manner; "the moment of his grandeur was when, after he had stated the argument of his adversary, with much greater strength than his adversary had done, and with much greater than his hearers thought possible, he seized it with the strength of a giant, and tore and trampled it to destruction." Sir James Mackintosh records that Fox "certainly possessed, above all moderns, that unison of reason, simplicity, and vehemence which formed the prince of orators." Burke pronounced him "the most brilliant and accomplished debater that the world ever saw." A man may be accomplished in statecraft and unrivalled in oratory, and yet may want the charm which renders him as worthy of love as of admiration. Few men whose statesmanship is indisputable, and whose pre-eminence as orators is acknowledged, have surpassed Fox in the graces which soften life and attract affection. His friends regarded him with idolatry. At the time of the French Revolution, when his party had become a fragment, Lord Thurlow said, "there are but forty of them, but there is not one of them who is not ready to be hanged for Fox." Lord Sidmouth, an uncompromising Tory, could not resist the fascination of his nature, and wrote, after knowing him personally, "I never knew a man of more apparent sincerity, more free from rancor, or even severity, and hardly any one so entirely devoid of affectation." Gibbon, another political opponent, admired in him "the powers of a superior man, as they are blended in his attractive character, with the softness and simplicity of a child. Perhaps no human being was ever more perfectly exempt from the taint of malevolence, vanity, or falsehood." It is unnecessary to supplement these testimonies with the eulogies of enthusiastic friends. Nor can there be any excess of partiality for him in the decision that Charles James Fox stands conspicuous among the English statesmen whose virtues ought to be kept in loving and perpetual remembrance. (W. F. R.)

FOX, GEORGE (1624–1690), the founder of the "Society of Friends" or "Quakers," was born at Drayton, Leicestershire, in July, 1624. His father, Christopher Fox, called by the neighbors "Righteous Christer," was a weaver by occupation; and his mother, Mary Lago, "an upright woman and accomplished above most of her degree," came of a family that had suffered much in former days of religious persecution. Both were members of the Church of England, and took great pains in the training of their children. George from his childhood "appeared of another frame than the rest of his brethren, being more religious, inward, still, solid, and observing beyond his years;" and he himself declares, "When I came to eleven years of age I knew pureness and righteousness; for while a child I was taught how to walk to be kept pure." Some of his relations wished that he should be educated for the church; but his father, after he had barely learned to read and write, lost no time in apprenticing him to a certain shoemaker, who also dealt in wool and cattle. In this service he remained till his nineteenth year, and acquired some proficiency in all the branches of his master's somewhat miscellaneous business; according to Penn, "He took most delight in sheep," but he himself simply says, "A good deal went through my hands. . . . People had generally a love to me for my innocency and honesty." In 1643, being upon business at a fair, and having accompanied some friends to the village public-house, he was deeply scandalized by a proposal to "drink healths," and abruptly withdrew in great grief of spirit. "When I had done what business I had to do, I returned home, but did not go to bed that night, nor could I sleep, but sometimes walked up and down, and sometimes prayed and cried to the Lord, who said unto me, 'Thou seest how young people go together into vanity and old people into the earth; thou must forsake all, both young and old, and keep out of all, and be a stranger unto all.' Then, at the command of God, on the ninth day of the seventh month, 1643, I left my relations and broke off all familiarity or fellowship with old or young." Thus briefly he describes what appears to have been the greatest moral crisis in his life. Of the four years which followed—the "times of the first workings of the Lord in him"—he has left but a confused account. They were on the whole years of great perplexity and distress, though sometimes "I had intermissions, and was sometimes brought into such a heavenly joy that I thought I had been in Abraham's bosom." He did not continue for many months to adhere to the letter of the command he believed himself to have received; he soon began to have some misgivings as to the propriety of his action in having forsaken his relations; and apparently without waiting for any new revelation, he ultimately conceded so much to the claims of natural affection as occasionally to visit those whom he had formerly thought it his duty to leave. Still, throughout this period his wanderings were very numerous, and covered a very wide area. He would go from town to town, "travelling up and down as a stranger in the earth, which way the Lord inclined my heart; taking a chamber to myself in the town where I came, and tarrying sometimes a month, more or less, in a place;" and the reason he gives for this migratory habit is that he was "afraid both of professor and profane, lest, being a tender young man, he should be hurt by conversing much with either." The same fear often led him to shun all society for days at a time; but frequently he would apply to "professors" for spiritual direction and consolation. These applications, however, never proved successful; he invariably found that his advisers "possessed not what they professed." Some recommended marriage, others enlistment as a soldier in the civil wars; one "ancient priest" bade him take tobacco and sing psalms; another of the same fraternity, "in high account," advised physic and blood-letting. About the beginning of 1646 his thoughts began to take more definite shape; or, as he himself expresses it, he began to receive more revelations. For example, as he was one day approaching the gate of Coventry, "the Lord opened to him" that none were true believers but such as were born of God and had passed from death unto life; and this was soon followed by other "openings" to the effect that "being bred at Oxford or Cambridge was not enough to fit and qualify men to be ministers of Christ," and that "God who made the world did not dwell in temples made with hands." "I had also great openings concerning the things written in the Revelations." He also experienced deeper manifestations of Christ within his own soul. "When I myself was in the deep, shut up under all [the burden of corruptions], I could not believe that I should ever overcome; my troubles, my sorrows, and my temptations were so great that I thought many times I should have despaired, I was so tempted. But when Christ opened to me how He was tempted by the same devil, and overcame him and bruised his head, and that through Him, and His power, light, grace, and spirit, I should overcome also, I had confidence in Him; so He it was that opened to me, when I was shut up and had no hope nor faith. Christ, who had enlightened me, gave me His light to believe in; He gave me hope which He Himself revealed in me: and He gave me His spirit and grace, which I found sufficient in the deeps and in weakness." With the knowledge he had thus received, Fox, towards the end of the year 1647, felt himself constrained to begin the work of his life as an itinerant preacher, the positive element in his teaching being to the effect that men ought to give sincere and earnest heed to the inner light—the light of Christ—which God had placed in every human heart. The scenes of his early labors and early successes were in the neighborhood of Dukinfield and Manchester, where he had "great openings and prophecies," and succeeded in establishing his influence over a considerable number of followers. From this date his creed grew rapidly in point of explicitness, especially on its negative and practical sides. For example, in 1648 it was revealed to him by the inner light that he was not to take off his hat to any person, high or low; that he was to use in addressing any single individual of whatever rank no other pronouns than the simple "thou" and "thee;" that he was not to bid people good morning or good evening; and that he was not to "bow or scrape with his leg to any one." Increasingly persuaded of the truth and importance of his message, he daily became bolder in the delivery of it. In the year 1649, as he was walking towards Nottingham on a first-day morning accompanied by some friends, he heard the bell of the "steeple house" of the city, and was admonished by an inward voice to go forward and cry against the great temple and the worshippers in it. Entering the church he found the preacher engaged in expounding the words, "We have also a more sure word of prophecy," from which the ordinary Protestant doctrine of the supreme authority of Scripture was being enforced in a manner which appeared to Fox so defective or erroneous as to call for his immediate and most energetic protest. Lifting up his voice against the preacher's doctrine, he declared that it is not by the Scripture alone, but by the divine light by which the Scriptures were given, that doctrines ought to be judged. The result of the disturbance which not unnaturally ensued was that he was seized by the constables and carried off to prison, where he was detained for some time, and from which he was released only by the favor of the sheriff, whose sympathies he had succeeded in enlisting. A similar adventure at Derby ended less favorably. For raising a discussion which seemed not unlikely to end in a breach of the peace in the church there, he was brought before the magistrates, and after examination, committed along with one of his comrades to the house of correction as a blasphemer;[1] and not till the beginning of 1651, after he had been a prisoner for almost a year, did he succeed in regaining his freedom. It would be here out of place to follow with any minuteness the details of his subsequent imprisonments, such as that at Carlisle in 1653, at London in 1654, at Launceston 1656, at Lancaster in 1660 and again in 1663, at Scarborough in 1666, and at Worcester in 1674. They are related with a certain monotony, which is yet far from being tedious or uninteresting, in the *Journal*, fortunately an easily accessible book. Suffice it to say that during these terms of imprisonment his pen was not idle, as is amply shown by the very numerous letters, pastorals, and exhortations which have been preserved by his followers; while during his intervals of liberty he was unwearied in the work of preaching and making disciples. While his labors were for the most part confined to the midland and northern counties of England, he found time in 1657 for a tour through Scotland, which, in his opinion, was not altogether without result. In 1669 he married the widow of a Welsh judge, Margaret Fell, who, with her family, had been among his earliest converts; but almost immediately afterwards his proselytizing ardor impelled him to proceed alone to Barbados, Jamaica, and the American continent. In all places visited by him there he met with a good reception, and was successful in making many converts. Shortly after his return in 1673 he was, as has been already noted, apprehended in Worcestershire for attending meetings that were forbidden by the law. He was ultimately set at liberty on account of errors in the indictment which had been drawn up against him, but this was not until after he had suffered a captivity of nearly fourteen months. In 1677 he visited Holland along with his followers Barclay and Penn; and this visit he renewed in 1684, extending his tour through a considerable part of North Germany. The later years of his life were spent mostly in London, where he continued to give public addresses, comparatively unmolested, until within a few days of his death, which took place November 13, 1690.

In personal appearance Fox was tall and strongly built, "graceful in countenance, manly in personage, grave in gesture;" in manner he was courteous and unaffected, "civil, beyond all forms of breeding," and "tender, compassionate, and pitiful;" essentially, he was "a heavenly-minded man, zealous for the name of the Lord, and preferred the honor of God before all things;" "a man that God endued with a clear and wonderful depth, a discerner of others' spirits, and very much a master of his own." These and similar characterizations by his friendly contemporaries, who, for the rest, do not pretend that he was in any way remarkable either for grasp of intellect or for profundity in learning, surely deserve some weight as against the somewhat prevalent opinion that Fox was nothing more than a vulgar charlatan whom we have "no reason for placing morally or intellectually above Ludowick Muggleton or Joanna Southcote" (Macaulay). The mere fact that he was able to attract to himself so considerable a body of respectable followers, including such men as Ellwood, Barclay, and Penn, is sufficient to prove that he possessed in a very eminent degree the power of conviction, persuasion, and moral ascendency; while of his personal uprightness, single-mindedness, and sincerity there ought to be no question.

The writings of Fox have been collected in three volumes folio,—the first containing his journal, the second his correspondence, and the third all that he has written in vindication of his doctrines. The *Journal* is especially interesting; of it Sir James Mackintosh has said that "it is one of the most extraordinary and instructive narratives in the world, which no reader of competent judgment can peruse without revering the virtue of the writer." Of other works attributed to him, perhaps the most curious is that originally published in London in 1660, entitled *A battle door for teachers and professors to learn singular and plural; you to many and thou to one; singular, one, thou; plural, many, you.* According to the *Journal*, however, this performance is not to be attributed solely to Fox. "J. Stubbs and Benjamin Furly took great pains in compiling it, which I set them upon, and some things I added to it." Indeed, it has sometimes been seriously doubted whether he was the real author of any of the publications which have been attributed to him; but this doubt, which proceeds merely upon the fact of his very imperfect literary education, seems to be conclusively settled by the clause in his will (which document may be seen in the *Harleian Miscellany*, vii. 599) referring to his "Bookes, Episeles, and Papers." The *Journal* was originally published in London in 1694, and has frequently been reprinted. A very useful edition is the seventh, with notes biographical and historical by Wilson Armistead, London, 1852. Several Memoirs of Fox have recently appeared,—one by J. Marsh in 1846; another by Janney, with dissertations on his views concerning the doctrine, testimonies, and discipline of the Christian church (Philadelphia, 1852); a third by the Rev. John Selby Watson (London, 1860). For details of the principles and history of the Society of Friends, see the article QUAKERS. (J. S. BL.)

FOX, RICHARD, an English prelate, statesman, and diplomatist, bishop successively of Exeter, Bath and Wells, Durham, and Winchester, and founder of Corpus Christi College, Oxford, was born about the close of the reign of Henry VI. He was a native of Ropesley, near Grantham, in Lincolnshire, and his parents are said to have been in humble circumstances. His education, however, was not neglected, for he was sent to school either at Boston or at Winchester, and thence transferred to Magdalen College, Oxford. His studies, in which he gained much distinction, were interrupted by an outbreak of the plague, and he went to continue them at Pembroke Hall, Cambridge. He next went to Paris, and there pursued the study of theology and the canon law. At Paris he became acquainted with Morton, bishop of Ely, then an exile, and by him he was introduced to Henry, earl of Richmond, who was preparing his invasion of England. He at once gained Henry's confidence, and managed for him the delicate business of getting assistance in men and money from the king of France. After the victory of Bosworth and accession of the earl as Henry VII., Fox, now a doctor of divinity, was made a privy councillor, and became one of the most trusted advisers of the king. Honors fell thick upon him. In rapid succession he was made a prebendary of Sarum, bishop of Exeter, keeper of the privy seal, principal secretary of state, and master of St. Cross, Winchester (1487). From this time he was almost constantly employed by the king in political affairs both at home and abroad. He was several times sent ambassador to Scotland, and several times to France. In 1491 he was translated to the see of Bath and Wells, and three years later to that of Durham. In 1497 he personally defended his castle of Norham when besieged by the Scots, until it was relieved by the earl of Surrey. The same year he negotiated a truce for seven years between England and Scotland. He also took part in the treaty for the marriage between James IV. of Scotland and Margaret, daughter of Henry VII. In 1500 he was chosen chancellor of the university of Cambridge, and held the office for two years. The same year he was translated to the see of Winchester, which he held till his death, a period of twenty-eight years. He was master of Pembroke Hall, Cambridge, from 1507 to 1519. During the reign of Henry VII. his influence was supreme in the state, no important affair being undertaken without consulting him. The king named Fox one of his executors, and especially recommended him to his son and successor Henry VIII. But his credit soon declined under the new king, partly owing to the character of Henry, and partly to the rivalry of the earl of Surrey. Amongst the chaplains of Bishop Fox at this time was Thomas Wolsey; and in order to counteract the influence of Surrey, Fox introduced Wolsey to the king. In a little while the new comer took precedence of both the rivals. Fox, however, did not suddenly lose the royal favor. In March, 1510, he was sent ambassador to France with Surrey and the bishop of Durham, and signed the treaty of alliance with Louis XII. In 1513 he attended Henry VIII. in his expedition to France, and was present at the taking of Terouenne. The same year he took part in negotiating a treaty with the emperor Maximilian. Fox was one of the executors of Margaret, countess of Richmond, and in this capacity had a share in completing the settlement of St. John's College, Cambridge. Continually mortified by the supremacy of his former protegé, Wolsey, and by the insults he had to endure from him, he at length (1515) withdrew from the court and retired to his diocese. The rest of his life was devoted to the discharge of his ecclesiastical duties and to works of charity and munificence. During this period he rendered great service to the cause of liberal education by his foundation of Corpus Christi College, Oxford. His first intention was to make it a monkish seminary, and for this he obtained a license. But on the advice of Oldham, bishop of Exeter, he changed his plan, and made it simply a school for the increase of learning. Bishop Oldham contributed largely to the cost of the buildings. Fox was founder also of free schools at Taunton and at Grantham. He became blind some years before his death, and was pressed by Wolsey to resign his see to him, but this he stoutly refused to do. He died, in a good old age, September 14, 1528.

---

[1] It was about this time that the epithet "Quaker" was first bestowed upon Fox and his friends (by Justice Bennett of Derby, it is said) because "they bade the people tremble at the word of the Lord." It soon passed into common use, and is to be found even in the Records of the House of Commons as early as 1654.

FOXE, John (1517–1587), was born at Boston in Lincolnshire in 1517. At the age of sixteen he entered Brasenose College, Oxford, where at twenty-one he took the degree of B.A., and five years later that of M.A. He attained a fair reputation for scholarship, was elected to a fellowship at Magdalen, and wrote several Latin plays on Scriptural subjects, of which the best, the *De Christo Triumphante*, was repeatedly published (London, 1551, Basel, 1556, etc.), and was thought worthy of translation into English by Richard Day, the son of the printer. Having become deeply interested in the more advanced religious inquiry of his time, he devoted himself to the study of Hebrew, of the ancient fathers, and of the doctrines of the Reformers; and at length his views coming to the ears of the authorities were considered so unorthodox that in 1545 he was deprived of his fellowship and expelled from the university. Here his punishment would probably have ended had not his stepfather taken advantage of his misfortune to deprive him of his patrimony. He was glad to accept a situation as tutor to the children of Sir Thomas Lucy, of Charlecote, near Stratford-on-Avon, who is famous as the prototype of Shakespeare's "Justice Shallow." But he did not long retain this situation, and he was in London in very destitute circumstances, when the duchess of Richmond appointed him tutor to the children of her nephew, the unfortunate earl of Surrey. During the reign of Edward, Foxe's circumstances were more comfortable. He married, and settled at Reigate, where, having been ordained deacon by Ridley in 1550, he preached and acted as tutor to the orphan children of Surrey throughout the rest of the reign On the accession of Mary, he was for some time protected by his pupil, the duke of Norfolk, but was at length obliged to seek safety by fleeing with his family to Basel, where he maintained himself by writing and correcting the press for the printer Oporinus. At the suggestion of Lady Jane Grey, he had already commenced a Latin history of the Christian persecutions. He now received assistance from two distinguished exiles, belonging to opposed sections of the Protestant party—from Grindal, who afterwards as Puritan archbishop of Canterbury distinguished himself by the noble firmness with which he maintained his convictions, even at great personal cost, and in opposition to the commands of Queen Elizabeth; and from John Aylmer, the tutor of Lady Jane Grey, who afterwards, as bishop of London, was one of the bitterest enemies of the Puritans. The first outline of the work appeared in 1554, and the first complete edition was published by Oporinus in 1559. About a year after the accession of Elizabeth, Foxe returned to England. The duke of Norfolk again extended to him his patronage. For some time he resided at the duke's manor of Christchurch in London, and on the duke's death he received a small pension. He became associated with John Day, the printer, himself once a Protestant exile, with whom he had many sympathies in common. We find him staying in Grub Street laboriously engaged in varied literary work, and occasionally preaching at St. Paul's Cross and in other parts of London. Church preferment was offered him by the Government, to which his works had rendered invaluable service. Cecil appointed him to the prebend of Shipton in Salisbury Cathedral, and he held for a short time the living of Cripplegate; but true to his Puritan views, which prevented him from subscribing to the Articles, he accepted nothing further, though more was offered him. In 1563 the first English edition of the "Book of Martyrs," in which several gross errors which had been exposed were corrected, appeared from the press of John Day.[1] Its popularity among a people which had just passed through the horrors of the Marian persecutions was naturally immediate and signal. The Government commanded it to be placed in each parish church; and more than any other influence it fanned the flame of that fierce hatred of Spain and the Inquisition which was the master passion of the reign. Nor was its influence transient. For generations the popular conception of popery has been derived from its melancholy and bitter pages. It was vigorously attacked by Catholic writers, and its accuracy in details has been successfully challenged, even such blunders as indicate gross over-credulity having been exposed; but the honorable lives of Foxe and his assistants place the work above the charge of wilful falsehood. If in all those who had been engaged in the persecution he could only recognize the spirit of cruelty and Antichrist—if in the noble Sir Thomas More he could only see "a persecuting spirit,"—this was but natural in a man who had witnessed the untimely destruction of some of the noblest spirits of the age, of some whom he had personally known and loved, and whose own career has been undeservedly blighted by the ruthless hand of persecution; and it must be remembered to his honor that in his firm grasp of the principle of religious toleration he rose far above his age and his fellow Protestants. He hated impartially *all* religious persecution, and he wrote to Queen Elizabeth pleading even for the despised Dutch Anabaptists. It is interesting to note that Foxe was one of the earliest students of Anglo-Saxon, and that John Day was the only printer of the day who could print the Anglo-Saxon characters. In 1571 they published, under the patronage of Archbishop Parker, an edition of the Saxon Gospels, dedicated to the queen. Foxe died on the 18th April, 1587, at the age of seventy, and was buried in the Church of St. Giles, Cripplegate. His life was written by his son, Samuel Foxe.
